TO OUR READERS.

— x —

IN vain have we tried to compose something new for this our periodical address; we must therefore hope that you will accept our thanks for your continued and increased encouragement. It enables us to go on cheerfully and with renewed resolution to use our best powers, and to spare no outlay for obtaining the earliest and most reliable information relative to our legitimate subjects. "When I have endeavoured to be successful I am contented," were the words of a modern statesman, and as we think he was correct we venture to adopt those words and to feel as he does.

THE EDITORS.

INDEX.

- ABERDEEN, BON-ACCORD BIRD SHOW**, 40; Horticultural Society, 300
- Aberdeenshire**, weather in, 284
- Abutilons**, ornamental, 108
- Aconitum spectabilis**, 375
- Aconitum**, 38
- Adelaide Botanic Garden Catalogue**, 411
- Adiantum palmatum**, 31
- Adulterations**, detection of, 291
- Aërides**, descriptions of, 450; various, 484
- Æchynanthus**, in pots, 360; splendens, 48
- Agricultural Show**, proposed international in London, 215, 291
- Alexandra Palace, Bird Show**, 118, 178; Rose Show, 223, 481, 488
- Allan, Mr. J. P.**, 134
- Almond trees**, 222
- Alströmmeria chilensis**, 413
- Alternanthera** green, 116
- Alyssum Wierzbickii**, and culture, 484
- Amaryllises**, culture, 189, 477; a plea for, 374; repotting, 418; seedling, 413; watering, 389
- American blight**, 63
- American**, harvest prospects, 489; corn crop, 475; exports to England, 98
- Amaryllis**, prizes for, 309
- Amateur**, 136, 288; defined, 381
- Ampelopsis hederacea**, 72
- Annual flower management**, 361
- Annals**, sowing hardy and half-hardy, 267, 287; and their culture, 319; distasteful to slugs, 348; at Regent's Park, 461
- Anthurium**, Andreanum, 37, 86; tridatum, 71
- Antirrhinum**, preservation of, 465
- Ants**, 247; r. aphides, 181, 113, 323; banishing, 381, 448; in greenhouse, 65; preserving aphides, 319
- Aphis**, destroying, 307; on Peach trees, 382
- Aponogeton distachyon** from seed, 363
- Apple**, notes on, 84; tree ornamental, 65; grafting old, 75; blooming season, 5; trees in pleasure ground, 6; trees cankered, 136; tree grub, 369; cordon unfruitful, 369
- Apples**, winter, 17; for orchards, 27; for market, 29; market, Baiton Free-Bearer, 45; and Apple trees, 50; protecting, 218; Northern Spy, 286
- Aquatic plants**, 325
- Araucaria Cookii**, 329
- Araucarias**, large, 15, 34
- Arbutus**, fruiting, 95; Uncdo in Yorkshire, 27
- Arrangement of flower beds**, 45
- Artichoke culture**, 249
- Arum crinitum** insectivorous, 483
- Asparagus**, beetle, 108; culture, 217, 240, 251, 253, 254, 438; cutting, 340, 349, 363; forcing, 74; planting, 470; prizes for, 300, 429
- Aucuba** pollen, 270
- Auricula Society**, National, 163, 300
- Auriculas**, 263, 318; hardy, 75; woolly aphid, 85, 133; culture, 94; at Slough and Loxford, 318; culture, 384, 397, 321; showing, 335, 357, 373; forced, 338; Crystal Palace, 340; Manchester Show, 336, 340; propagation, 343; repotting, 362; buying, 363; Society's Show, 371; at Falloworth, 431; striped, 470
- Azalea Souvenir du Prince Albert**, 166
- Azaleas**, culture, 343, 435; in December, 3; after flowering, 363; at Fulham, 308; Ghent Excellence, 114; liquid manure for, 55; mollis, 212; propagating, 212; white for forcing, 212; unhealthy, 388
- BALSAM CULTURE**, 295, 400
- Bamboo**, in Annam, "Commercial Plants," 223; not growing, 343
- Bantams**, 347, 383; varieties of, 420
- Bark of tree**, removing, 288
- Barley cultivation**, L. 4, 153, 174
- Bast**, 471
- Bath and West of England Poultry Show**, 198, 320, 384, 457; Flower Show, 452, 467
- Bause, Mr. F.**, 108
- Beans**, Broad, 111; dwarf for small garden, 116; experiments with Scarlet Runners, 225
- Bedding-out**, 324, 361; stock for, 239
- Bedding plant arrangement**, 359
- Bedding plants**, preparing, 22
- Bee-keepers' Association Show**, 492
- Bees**—keeping, past, present, and future, 23; keeping in Kansas, removing hives, 42; warmth and ventilation, 60; size of bar-framed hives, feeding, dysentery, fallen comb, uniting swarms, 80; mortality, 98; feeding, wintering, 99; Scotch Society, 110; bar-framed hives, 120; wintering, bar-frame hives, 140; chloroforming, wintering, ventilating, introduction of Ligurian, 168; "The Apiary," weak hives, deserted hive, stings, 160; wintering, 178; Ligurian history, 177; sting remedy, apiary work, 178; wintering, 196; feeding, bar-framed hives, 197; mice in hive, 215; wintering, 216; Italian r. British, 235; spring overhaul, crooked combs, 250; in California, 253; Ligurian, swarming r. non-swarming, 254; bar-framed hive management, 273; swarming r. non-swarming, feeding, 274; Ligurian r. black, 291; notes on ancient writers, 292; in America, husbandry of, 311; natural death of, 312; dying, 320; husbandry of, 330; this season, for profit, 347, 348; transferring, 348; hives, swarming r. non-swarming, 367; feeding, 368, combs in hives, 368; bar-framed hives, box r. straw hives, 385; Ligurianizing, 386; dividing, wintering, bar-frame hives, 404; management of, 421; bar-frame hives, eking of, cast-out of hive, comb foundations, 422; unfavourable seasons, 439; early swarms, 439; feeding, 440; prospects, 440; tapping flowers, 438; seasons of 1877 and 1878, 438; and bees, 475; comb foundations, 475; hive chloroformed, 476; strengthening, 476; royal cells, 476; four swarms, 473; pasture for, 483
- Beet**, culture, 315; sowing, 365
- Begonias**, Frobelli, 15; Moonlight, 69; Saundersii semperflorens, 106; tuberous-rooted, 101, 149, 301; cuttings, 260; cuttings of tuberous-rooted, 307
- Belladonna Lily** planting, 343
- Berberis Darw**
- Berberis Imray**, 71
- Biennial** defined, 436
- Biennial flowers**, sowing, 379
- Bignonia**, insects on, 136
- Bilbergia paleacensis**, 171
- Birch tree**, large, 68
- Bird house**, 160
- Birds**, training, 421
- Birmingham Columbarian Society's Show**, 20
- Birmingham Cattle and Poultry Show**, 273, 328
- Bitter Vetch**, 433
- Blackleg in cattle**, 418
- Blasting tree stump**, 219
- Blinds**, outside, 153
- Blossom**, impregnating, 127
- Blue flowers** for bedding, 22
- Boller, Richardson's**, 297
- Bone manure**, 75
- Bones**, dissolving, 193; for manure, 364
- Border flowers**, 93, 109, 146, 163, 305, 254, 304, 357, 453
- Boronia** and culture, 430
- Botanic Society (Royal)**, 68; Show, 241, 318, 391, 447
- Botanical Exchange Society**, 281
- Bouvardia** culture, 277, 323
- Box hedge**, 75
- Brahma**, cockerel, 140; feeding, 100
- Brahmas** lame, 274
- Briers** for stock, 363
- Bridge Hall**, 300
- Bristol Horticultural Show**, 248
- Bristol Poultry Show**, 196
- Brocchis**, for succession, 37; culture, 82; transplanting, 92, 105; sowing, 249, 324; Suttons' Late Queen, 284; culture, 341; Knight's Protecting, 341; abundant, 388
- Brunsvigias**, 45; and culture, 10
- Brussels Sprouts**, 102
- Budding**, quill, 450
- Bulbs**, removing, 36
- Burnham Beeches**, 270
- Butter**, from Holland, 215; origin of, 247
- Butterflies**, 300; early, 88
- CABBAGE CULTURE**, 122
- Cabbages** for London, 383
- Calceolarias**, herbaceous, 376
- Calceolarias (Royal) Horticultural Society**, 303
- Californian seeds** from, 465
- Calves**, rearing of, 382, 399
- Camellias**, shedding buds, 37; in December, 3; not flowering, 75; potting, 94; culture, 133; shading, 167; leaves sticky, 193; at Waltham Cross, 287; cutting down, 281; leaves falling, 291; large, 281; culture, 435; management of, 455
- Canaries**, high-coloured, 494; treatment, 478
- Canary-breeding notes**, 272; featherless, 274
- Canizaro House**, Wimbeldon, gardening at, 210
- Carbolic acid** disinfectant, 254
- Cardamine pratensis**, double, 418
- Carnation and Picotee Society**, 10, 196; Show, 378
- Carnation**, layers, 193; La Belle, 39
- Carnations**, in pots, 94; in the north, 384; select, 249
- Carpet-bedding**, 436; plants, 115, 116, 471
- Carrier Pig** on, 22
- Carrots**, culture, 143; early, 134; forcing, 114; field-culture of, 270
- Cater & Co's prizes**, 35
- Cassia corymbosa** culture, 362
- Catepillar**, vegetable, 130
- Catepillars**, their colour, 253
- Cattle** for profit, 273
- Cauliflower**, culture, 61, 104; for succession, 37
- Ceanothus rigidus**, 300
- Cedars**, felling, 470
- Celery** culture, 47, 236, 276, 286, 397; planting, 224, 361; sowing, 114
- Cemetery**, arrangement, 468; planting, 115
- Centaurian's death**, 242
- Cephalotus follicularis**, 128
- Chalk**, trees and plants on, 137
- Channel Islands**, 79
- Charcoal manure**, 99
- Chatsworth Gardens**, 372
- Chesew, fancy**, 367
- Chione obliqua**, 15
- Cherries**, forcing, 135, 325; management in house, 211; house, 287; Morello standards, 64; orchards, 324
- Cherry house** management, 362
- Chesnut Sunday**, 379
- Chicken coop**, a simple, 39
- Chickens** crop distended, 386
- Chickens**, management 439, of spring, 271
- Chickweed** as a barometer, 42
- Chionodoxa**, 220
- Chorozemas**, 166
- Christmas Rose**, 187
- Chrysanthemum (Putney) Society**, 134
- Chrysanthemums**, early-flowering, 6, 15; late-flowering, 34; notes, 40; late-blooming, 52; late, 63, 88; in pots, 340, 398; in winter, 143
- Cineraria** flowers discoloured, 363
- Cinerarias**, Cape, 436; culture, 224; new, 243; withering, 251
- Classes** at shows, 55
- Clematis**, sowing, 75; show, 360
- Clematises**, light-coloured, 37; for wall, 231
- Clerodendron**, Balfourianum, 136; in August, 75; fragrans culture, 470
- Climbers**, summer-flowering, 56; hardy, 72
- Clover**, culture, 251; and grass culture, 232
- Clubbing of Cabbagewarts**, 37
- Cochine**, feeding, 160
- Cocoon** fibre refuse, 75
- Coffee plantation**, 228
- Colour arrangement in beds**, 251
- Comfrey**, Prickly, 193; culture, 214, 253, 360, 435
- Composts**, root-producing, 100
- Conoclinium lanthimum**, 205
- Conservatory**, management of, 211; heating, 212
- Coop for fowls**, 50
- Cooper, Mr. S.**, 68
- Cordiceps Robertsi**, 130
- Corn averages**, 273
- Cornish gardens**, 100
- Cotton cake** for cattle, 139
- Covent Garden Market**, 24, 42, 60, 50, 100, 120, 140, 160, 178, 198, 216, 236, 254, 274, 292, 312, 320, 348, 368, 386, 404, 422, 440, 476, 494
- Cow**, characteristics of good, 235; and pig, 274
- Cows**, kicking, 20; best for dairy, 41; food for, 98; management, 99, 308; feeding, 159; quick milking, 273
- Crassula** culture, 381
- Crataegus pyracantha**, 72
- Crinum Verschoffianum**, 391
- Crochets** and pheasants, 263
- Crop valuation**, 397
- Crops**, near London, 312, prospect of, 461
- Crossandra guineensis**, 171
- Crotons** not flowering, 343
- Crowfoot**, 394
- Cryptomeria japonica**, large, 108
- Crystal Palace**, 166; Bird Show, 135; Show, 411
- Cuckoo flower** double, 378
- Cucumbers**—bed making, 73; culture, 115, 260, 288, 306, 434; earliest, 222; for exhibition, 470; failing, 436; failures, 167, 270; fire-heating house, 17; forcing, 36, 102, 230, 342, 383; in greenhouse, 115; meaty bug on, 35; liquid manure for, 399; planting, 192; in March and April, 399; ridged, 361; roots diseased, 17, 95; for seed, 471; soil for, 308; sowing, 53; unhealthy, 74; Woolley's Telegraph, 284
- Current**, trees, moving large, Black barren, 75; pruning, 33
- Cuttings**, 239; propagation by, 179
- Cyathea medullaris**, 467
- Cyclamen**, lecture on, 134
- Cyclamens**, 285; double, 288; from seed, 184
- Cydonia japonica**, 389

Cypripedium Boxallii, 145
Cypripediums, and culture, 184

DAHLIA, CULTURE, 467; CUTTINGS, 191

Dairy, management, 308, 326, 382; in America, 329; for butter, 329
 Daisy, 118; propagation, 436
 Dale testimonial, 107
 Damping-off, 337
 Daphne, cneorum unhealthy, 115; *indica rubra*, 166
 Darlington Bird Show, 79
 December flowers, 81
 Delphiniums, exhibiting, 331
 Dendrobium Freemanii, 145
 Dendroseris macrophylla, 334
 Deutzia gracilis, culture, 351, 335; pruning, 307
 Dew, 43, 63, 107
 Diary, 17
 Dicentra in California, 484
 Dictamnus rubra, 304
 Digging, 375, 332
 Dipladenia culture, 123
 Dorchester Poultry Show, 77
 Dorsetshire Bee-keepers' Association, 468
 Dormouse, 348
 Dracaena, *E. dracaena*, 283; terminalis a room plant, 166; from seed, 149
 Draining, 76
 Drip, 55
 Ducks, rearing, 373; v. slugs, 425
 Dundee Horticultural Society, 107
 Dunnevan, Vines at, 429
 Dungee for manure, 239
 Durham florists, 461
 Durham and Northumberland floriculture, 188
 Durham and Northumberland Horticultural Society, 378

EARLY WOOD POULTRY-YARD, 493

Easter decorations, 334
 Eccremocarpus from seed, 115
 Echeveria retusa, and culture, 188
 Echeverias, seedling, 116
 Edinburgh Flower Show, 321
 Egg production, 79
 Egg-producers, profitable, 80
 Eggs, in winter, 21; weight of, 59; dried, 99; ill-flavoured, 120; for setting, 139; imported, 140; scarcity of, 213; differing in colour, 216; size of, 235; large, 312; preserving, 422
 Entomological exhibition, 246
 Epacris for early flowers, 242
 Ergot causing disease in cows, 308
 Erica, candidissima as a decorative plant, 447; vagans culture, 138
 Ericas, 150, 376; propagating, 431
 Escallonia macrantha, 249; culture, 297
 Essex Horticultural Society's Show, 453
 Eucalyptus globulus, 242, 470
 Eucharis amazonica, culture of, 304; fine, 149, 166; repotting, 136; weak, 74
 Euphorbia splendens, culture, 470
 Evergreens, pruning, 325
 Ewes and lambs, management of down, 116, 137

FARM-HOUSE MANAGEMENT, 56

Farm-work on the home, 37, 76, 96, 117, 138, 155, 175, 194, 314, 322, 323, 271, 290, 309, 327, 345, 364, 383, 400, 420, 437, 456, 473, 491; work, seasonal, 117; large American, 158; schools, German, 176
 Fasciation, 17
 Fattening animals, 158
 Feather cloth, 176
 Fern, culture, 173; crested, 174; hybrid, 108; Royal, 307; sowing, 93
 Ferneries, hardy, 313
 Fernery, 191
 Ferns, British, 313; for glass case, 381; repotting, 37; shading, 345, 377; stove, 343; Tree, 374; withering, 183
 Fertilis Moorei, 334
 Figs-and its blossom, 80; culture, 250, 387, 305, 325, 361, 434; forcing, 36; in pots, 94, 153, 192; soil for, 136; as standards, 184; tree unproductive, 351
 Fir, large Silver, 430
 Fire-lighting, 198
 Flaxworts, 109
 Fleas in fowl house, 386
 Flora of a former age, 243
 Flower Mission, Bible, 483; American, 453
 Flower, beds arrangement, 281, 260, 228; planting circuit, 336; manure for, 383; garden, 310; management of, 310; shows and judging, 81; pots, self-registering, 481
 Flower show, a people's, 337
 Flowers, economic uses of, 9, 112; preserving cut, 149; hardy in January, 305; planting out, 398
 Food, warm, 36
 Forestry in April, 304
 Fontaine, Rev. J., 53
 Fowls, in France, 30; water for, 41; food required by, 80; crossing, 80;

FOWLS—Continued.

selecting stock, 100, 140; losing feathers, 160; trespassing, 178; not laying, 216; management and feeding of, 216; for profit, 348
 Fraxinella culture, 343
 Frice, Professor, 149
 Frost and snow, poultry in, 96
 Fruit, trees, pruning, 55, 111, 121, 223, 318; trees, for small garden, 53; making pyramids, 56; for shady place, 56, for south wall, 56; tree protection, 67; trees, grafting out, 132; trees, ornamental, 167; blossoms, protecting, 363; garden, management of, 210; houses, management, 211; prospects, 88, 242, 256, 287, 302, 350, 357, 371, 430, 478; crops, American, 300; tree, transplanting in summer, 270; trees, training pyramidal, 333, thinning, 381; damage to trees in Kent, 356; tree training, 417; disappearing, 438, 454, 465, in Wilt, 448, in Gloucester, 449; and corn prospects, 466, 475; trees, destroying insects on, 454
 Fuchsias, racemosa, 108; serratifolia culture, 307; insects on, 363; in pots, 340; select, 471
 Fungus, fossil, 84

 Lilliums, 464; in pots, 266
 Lilly of the Nile, culture, 436; in winter, 17

Lily of the Valley, 69; home-grown, 4
 Lime, for garden, 172; application of to soil, 212; to use as manure, 347
 Linums, 109
 Liriodendron tulipifera wood, 387
 Lobellias, from cuttings, 244; raising, 37
 Lomaria gibba, 115
 London extension, 280
 London International Horticultural Exhibition, 483
 Love Birds, 403
 Loxford Hall Grapes, 383
 Luccococcus rupicola, 375
 Lucerne sowing, 309

MADEIRA VINEYARDS, 53

Magnolia for south wall, 17
 Maidstone Rose Show, 337
 Manchester National Horticultural Show, 242, 429, 444
 Manold, culture, 310, 343; manure for, 331
 Manure, changing, 17; exposing, 140
 Manures, liquid and solid, 41
 Manuring, 275, 321
 Maréchal Niel Rose, 354
 Market gardens and nurseries of old London, 147, 460
 Marnock, portrait of Mr. R., 300
 Mealy bug, destroying, 471
 Meat, trade, American, 98, 253; imported, 235; production, 475
 Melbourne Botanic Gardens, 394
 Melon houses, 490
 Melons, culture, 114, 192, 230, 260, 306, 308, 341, 382, 434, 499; failing, 471; fertilising, 423; soil for, 308; sowing, 55; temperature, 173
 Memorial trees, 15
 Mentha pulegium culture, 95
 Messenger's wall protector, 204
 Mice destroying bees, 215
 "Midland Naturalist," 85
 Mignonette culture, 180, 367, 434; pot culture, 141, 251
 Milk, 50; profit, 79; supply, 98; testing, 130, 367; increasing, 139
 Mistletoe propagation, 55
 Moffatt, death of Mr., 35
 Moths in gardens, 396
 Mowing machines, 294
 Mulberry propagation, 471
 Mulching, 379
 Murray, Mr. Andrew, death of, 54
 Mushroom, beds, 417; characteristics, 306; culture, 74, 161, 236; spawn, 108
 Myrobella, 17
 Myrtles, not flowering, 55; soil for, 343

NAMES, POPULAR OF PLANTS, 263

Narcissuses, 259
 National Peristeric Society, 21, 40
 National Rose Society, meeting of, 88
 Nectarine, early, for orchard house, 37; tree pruning, 135
 Nectarine, forcing, 288, 341, 417; falling, 390; in houses, 488; training, 306
 Nemophila, discoidalis, 330; sowing, 116
 Nepenthes culture, 342
 Nertera, 95; depressa culture, 436
 Nest egg, to make, 41
 Nests, 365
 Newcastle Show, schedule of, 309
 New Zealand plants from seed, 288
 Night soil, 55
 Nikaw Palm, 68
 Nitrate of soda, applying, 364; use of, 212
 Northumberland florists, 461
 Nurseries, old London, 486
 Nursery garden tenant, 336
 Nuts, storing, 192

OAKS OF HIRNAM, 226

Oats, cultivation of, 213
 Oats and ends, 303
 Oleander buds falling, 75
 Onion, native, 88
 Onions, culture, 163, 306; for pickling, 380; sowing, 190, 488; Tree or Mul-tiplifying, 203
 Orange, culture, 325; trees, value of 418; tree unhealthy, 115
 Orchard house, 395; management, 55, 115, 192, 240, 342; routine, 459
 Orchids, culture, 136, 230, 307, 342; not flowering, 75; choice garden, 450; imported by Mr. Bull, 333, in January, 31; at Kew, 133; Lord Londesborough's, 184; at Loxford, 323; management of, 454; select, 484; at Messrs. Vetch's, 246
 Oropanax Thibaultii, 71
 Orobus vernus, 433
 Osborn & Son's Nurseries, 222
 Oxford, Flower Show at, 453

PAINT FOR STOVE INSIDE, 251

Paley Poultry Show, 39
 Pansies, 53; in pots, 307
 Pampas Grass, after flowering, 193; transplanting, 325
 Pandanus unguifer, 171
 Pansies, dying in winter, 453; early planting of, 210; size of, 470

Paraffin, lamp for heating, 134; stove
r. flues, 92, 261; stove for heating,
263; heating by, 430
Parakeet's eyelids ulcerated, 348
Paris, Universal Exhibition, 196, 329,
429; Poultry Show, 457, 473; jurors,
473
Parrot self-plucked, 120
Parsley culture, 328
Parsnip culture, 180
Pasturage influence, 119
Pasture and park land management,
75, 95, 194
Pastures, improving, 403
Peaches—buds dropping, 56; Conder,
45; culture, 220; early, 37; forcing,
74, 114, 153, 263, 341, 380, 417; and Nec-
tarine forcing, 192; in houses, 488,
490; for orchard house, 37; leaves
blistered, 399; stoning, 363; tree
training, 360; trees, pruning, 136,
young, 95, 251
Peach-trees, 175, 185
Pear, for west wall, 136; trees, prun-
ing, 247, 362; tree, root pruning,
471; growing in Sussex, 420; for
west wall, 138
Pears, at Holme Lacy, 88; protecting,
Pears, 284, 293; for August, 270; cul-
ture, 44; dying on, 471; early, 64,
132, 144, 163, 190; in paraffin, 470;
selection, 191; sowing, 47; for suc-
cession, 57
Peat charcoal, 268
Peat soil sandy, 499
Pecariquons, lilac zonal, 37; for ex-
hibition, 95; zonal in winter, 145,
158; scutellum, 168; Joseph So-
mers, 223; stopping, 250; liquid ma-
nure for, 322; trusses divided, 320;
for winter, 455
Pencarrow, 69
Perennial flowers from seed, 236
Peristerion Show, 73; Society, 59;
President's address, 157
Periplexities, 207
Petroleum antiscorbutic, 329
Phenazants, and Crocuses, 281; ma-
nagement of Silver, 274
Philpott & Co.'s nursery, 429

From observations taken near London during forty-three years, the average day temperature of the week is 41.1°; and its night temperature 33.3°.

A NEW YEAR'S EXPECTATIONS AND COUNSELS.

LONGFELLOW, the American poet, has described the advance of a child's life under the image of a brook gradually growing into a river, the most interesting point being the time when the girl is just, only just, passing—at that instant passing—into "a woman." She is supposed to be dreading the future, and not wishing the sweet, sweet girlhood to slip so soon away.

"Standing with reluctant feet
Where the brook and river meet,
Womanhood and childhood fleet.

"Gazing with a timid glance
At the brooklet's swift advance,
On the river's broad expanse."

She seems to belong to both, and does not wish to be parted from the past. Something of this same feeling we all, I think, more or less have on the opening days of a new year. We do not wish at first to be identified with it: we meet it with "reluctant feet." We cling to the old year. We at best wish ourselves to belong to both. We love the past, we shrink from the future. If the past year has been past, very smooth, or even joyous, to us, we naturally fear that the next may not resemble it. If the past year has been cloudy, we fear the clouds may gather still heavier and the days be darker in the future.

Nationally no new year, perhaps, has been looked forward to with greater doubt than this. A kind of tremor passes through us, as we say, "I wonder what will happen to us before the year is over. Shall we be actually at war, or only, as last year, be lookers-on and hearers, and almost, through the picture press, seers of its horrors, or worse, far worse, participators?" Leaving these matters as being out of our range, we will turn our thoughts to the subjects embraced by our Journal. Peace and prosperity are wonderful helps to horticulture, and yet even in the most troubled times, and with those persons most exposed to trouble, gardening has proved to be a solace and resource, though we may be surprised that such could possibly find time for horticultural thoughts and plans; yet Mr. Thorne in his excellent "Handbook to the Environs of London" tells us that at Wimbledon House, where Charles I. was frequently a resident, and took much interest in the gardens—and, mark it—he only a few days before his trial ordered some seeds of Spanish Melons to be "planted in his garden at Wimbledon." Surely gardening must have, like music, a charm to soothe the troubled breast. And then all sorts and varieties of men—men with minds, and feelings, and opinions most opposite—have found a like charm in a garden. The very place I have just mentioned, Wimbledon House, passed from Charles into the immediate possession of General Lambert, a stern republican warrior, a hero at Marston Moor and other like battles, and yet this man, so different in feelings, and habits of thought, and opinions to the King, was, we are told, "as fond as the King of the gardens, was, we are told, as fond as the King of the gardens, turning florist, and possessing the finest Tulips and Gilliflower flowers that could be had for love or money." Then also,

when, as upon the King, so upon General Lambert, dark days came and he was banished for life to the isle of Guernsey, "he there lived upwards of thirty years, amusing his leisure with horticulture." I could scarcely, I think, choose two more striking instances of the power and charm of a garden over men of opposite principles. It is the same still. Outside of Birmingham the villa residents are as interested in their gardens as similar residents outside of Bath, and yet their business occupations are so different.

Then, again, I have noticed that although there are many men in professions and trades who have no love for their callings and merely follow them for a living, yet there are always two exceptions—those who earn their bread by music or gardening. Passing from the former, let me take the latter. Gardeners everywhere, and I think in all circumstances, love their profession; they, though often hard-worked, and overweighted with families perhaps, yet delight in their work and its surroundings. Who beside a gardener reads as much about his business? Tradesmen, as a rule, do not spend their winter evenings reading about their trades; they have a fancy (perhaps gardening) of which they love to read, but a gardener reads his gardening books, aye, and his *Journal of Horticulture* from the mere pleasure, as well as because of its help in his calling. I have often noticed a gardener pause in his work to admire some special beauty in a flower, or handle lovingly and with becoming pride some particularly good fruit or vegetable of his growing. Gardeners, too, have not unfrequently some special pet flower or fruit in their masters' gardens, some little love of their own. Nor is the charm of horticulture alone felt by them. Who are, as a rule, young gardeners but the sons of gardeners? "Well, sir, he has a kind of took to the garden somehow," said a gardener to me of his son; "so I suppose he must follow old Adam's trade too."

Next, what has been the past year to us? Not, I fear, very cheering—cold, overmuch wet, and too little sun must be the characteristics of the year 1877. Flowers dank with unwholesome moisture, and their beautiful colours not drawn out by sunlight. Fruits "conspicuous by their absence," in the words of the veteran Earl Russell. Few amateurs' fruit trees laden—heavily laden—with purple, or golden, or green fruit. Plums not to be had, Pears few, Apples only plentiful in some places. Yet there is always a compensating system going on throughout nature. A fruitless season means also a resting year for a tree and a growing year for new and healthy wood; and thus I expect next autumn we shall have a fruitful season again. This is one of my expectations. Look at the Holly plant at Christmas, 1876—not a berry was to be had, the Holly tree had nowhere borne its fruit; but look into our churches this Christmas, and we see them all aglow with the best decoration of all—Holly branchlets brilliant with numberless berries. That next year will be a better year for gardening is from the law of compensation one of my fond, and I hope not ill-founded, expectations.

There has always been going on, sometimes faster sometimes slower, yet going on still, a progress in horticulture.

No. 1357.—VOL. LIX., OLD SERIES.

No. 875.—VOL. XXXIV., NEW SERIES.

Take the time of Charles II., when as it is well known the first Pine Apple was grown in England and presented to that monarch. Here was progress. But take another fruit of the same reign—the humble Gooseberry. Says dear old gossiping, yet observing, Pepys, “I came to Hatfield before twelve o'clock, and walked all alone to the Vineyard, which is now a very beautiful place again; and coming back I met with Mr. Looker, my Lord's gardener, who showed me the house, the chapel with brave pictures, and above all, the gardens, such as I never saw in all my life; nor such good flowers, nor such great Gooseberries, as big as nutmegs.” Fancy what our Lancashire Gooseberry-growers would think now, or for many years past, of Gooseberries no bigger than nutmegs! What progress in them! So of Apples. The very old varieties, such as the Golden Pippin, are nearly all small in size; the best modern sorts are not only fine in flavour but large in size. Progress again. So of Strawberries and other fruits. At the present time vegetables are very abundant, but not so in the olden days. Says Miss Meteyard in her “Sketch of the Art of Pottery in England,” “The quality and production of pottery during the Middle Ages and its relation to food cannot be overlooked. Vast joints of meat, or even whole animals, served without vegetables, required but a few huge dishes, a silver or pewter charger, a wooden tray, or a large clumsy slab of ill-baked earthenware. Vegetables were a rarity. Salads, sweet herbs, Peas, Beans, and Leeks, and one or more variety only of the Cabbage plant, was cultivated by the monks and in the gardens of the more enlightened portion of the nobility; but as ordinary articles of diet they were little used or known. Greens were indeed salted for winter use in 1289. Both Cabbages and Onions were imported from the Netherlands through the eastern ports, and the traffic continued to the close of the sixteenth century. But it was rather the hindrances to peaceful occupations than popular ignorance of the common vegetable products which made them scarce in the Middle Ages. The wars and civil feuds which occupied the nobility and took the agricultural population from their useful labours, the custom of feeding vast bodies of servile dependants in the baron's hall, were amongst the causes that hindered the progress of horticulture.” It always declined during war. In Henry VIII. and Elizabeth's time it revived, for there was not much war. “Compared with vegetables, fruit seems to have been tolerably abundant in this country during the Middle Ages. The Strawberry, the Raspberry, and others were indigenous, and when so large a part of the country was covered with wood, morasses, and heaths, the wild fruits must have flourished prodigiously, and furnished no inconsiderable portion of food to the towns near. The Romans brought the Vine, the Peach, the Chestnut, the Fig, the Pear, the Mulberry.” The monks cultivated and improved, but did not introduce. No fruit till the Tudor time formed part of a meal in confections and jellies. Thus we learn by comparing different periods what a progress has been in gardening products. If I entered upon the improvements in garden implements, and appliances, and arrangements I should have a fruitful and vast field of inquiry, and one of abundant interest; but of this I cannot find room to speak. Suffice it to say that in all these the great advance has been in the last quarter of a century.

I pass on next to flower shows. I grant at the outset that I should best like if these were attended by crowds, every one having an interested and intelligent love of the productions of a garden; but we must take things as they are, and all we must aim at is that the fruits, flowers, and vegetables shown go on improving. Suppose a flower show with only tents containing the exhibits and no other attractions, would they be filled? Oh, no. There would be a few—“fit audience, though few,” as some might say—a few most intelligent observers and delighted admirers of the things shown, but such shows would not and could not pay. Flower shows for gardeners only would never do. Take things, I say, as they are and make the best of them. I have been connected for seven years with a capital, most successful, and well-paying district show. To pay we must have numbers, but how get them? Why, hire the best band to be had and pay fifty guineas for it, as we do. That will bring in all the carriage owners of the district near—aye, and far too. The great people come in—fair ladies with exquisite toilets, gentlemen with exquisite equipages. Then the professional classes come, then the trade classes, and a vast number of the humbler classes come when, late in the afternoon, the entrance is reduced to sixpence.

Do all these people come to see the flowers and fruits? No,

only a certain percentage do; but then many more have their interest aroused, and here and there a taste is on that day caught and which will last. Let no one dream of inducing crowds to come and enjoy or even look at flowers. Crowds come together to see each other, sweethearts to meet each other, and others in search of sweethearts. Crowds come to see and be seen, and some to observe with a definite purpose. One man to note the horses. That little dress-maker with her sharp eyes has an eye to business, and is watching Lady So-and-so's dress and how the London fashions now are. Why even people do not all come to church from the highest motives; we must not expect them, therefore, to come to other places with eyes bent upon the particular object of the meeting. Have the best music, have also a tea tent as well as other usual refreshment tents. Have plenty of innocent drinks; beer heavily salted increases thirst, not allays it. Have amusements, but do not have fireworks; they keep people late, and then the public houses do a roaring trade. Once allow them and you injure deeply a good cause. A flower show, like a garden party, should be an innocent and early-hour recreation. I notice that the greatest improvement is in the cottagers' classes, and here is just what should be—a higher taste given, and labour becoming more and more skilled. But I counsel all managers of shows to avoid narrowness on the subject of musical and other attractions being combined with shows. Have a wide net if you want to catch many fish, remembering that only a few come to see the flowers, and fruit, and vegetables; but each year more and more will come, for Nature at her best is always attractive, and her spell will be laid upon here one and there another, and the one who came only to see others returns a devout lover of some plant that has gone home to his heart. Having noticed the improvements in the cottagers' exhibits, I would also remark that not seldom some one production of his garden is the cottager's pet, and it being so he grows it to great perfection, and often, and most properly, with an eye to sale. I have known the Raspberry so made a hobby of. Some of the best I have ever known came out of a cottager's garden, where they each year help to pay the rent. It is a tree-shaded garden, and the Raspberry flourishes under trees. Then, too, it is well to cultivate an eye for tree-beauty. Charles Kingsley had this. In one of his later works, speaking of the time of the Crimean war (1854), he thus writes of a successful artist:—“He paints no longer, save when he chooses, and has taken a little old house in one of those back lanes of Brompton, where islands of primeval nursery garden still remain undevoured by the advancing surges of brick-and-mortar deluge. There he lives, happy in a green lawn and windows opening thereon, in three Elms, a Cork, an Ilex, and a Mulberry, with a great standard Pear, for flower and foliage the queen of all suburban trees.” How that description makes us to see that lawn and its trees, and the big Pear tree best of all!

But I must bear in mind that this is not only the *Journal of Horticulture*, but it is also the *Home Farm, and Poultry, Pigeon, and Bee Chronicle*. The “Home Farm” is a capital addition, for this is essentially a journal of home pursuits, and the new department is sure to be as welcome as it is appropriate. As to poultry, I fear there has been no progress, save that the effect of high-class birds being so generally bred the ordinary poultry of the farm is much better than in former and far-back years. Whether poultry shows are about to dwindle and die out, save the great metropolitan ones, is a doubt. Everything is getting more central, which means more Londonified. Bristol Show gone; Birmingham only second-rate; county shows disappearing; great breeders advertising the sale of their stock and giving up. I hope a re-action may take place; whether it will remains to be seen. Pigeon shows do not seem to be hit as hard as poultry, and the London shows have been pre-eminently beautiful. Then the fancy pigeon is easily kept in a suburban garden; he wants little room, his home occupies but a few feet. In regard to pigeons I notice that homing pigeons are now being made useful in a very interesting manner by our Scotch neighbours, for, as appears by an account in another column, carrier pigeons are now employed with advantage in taking messages from boats engaged in the Scottish herring fisheries when no species of telegraph is available.

In conclusion I would give a few words of counsel to gardeners. It is notorious that hundreds of male servants, particularly those connected with indoor service, are now out of employment, the cheaper female servants taking their places these dear times. A great number, too, of coachmen and grooms find it a hard matter to get new masters, for carriages

and horses have to be given up. Gardeners are, happily, better situated, for gardens must be cultivated, but still I hear of the gardening staff being diminished. This is no time for making changes unless with great care and forethought. I counsel economy and content. If you are anything like comfortable try and stay where you are. "Rolling stones gather no moss," and "Three removes are as bad as a fire." Remember a wife's heart aches when she sees her chairs and tables put on a cart to be carried to another, perhaps inferior home, or, worse still, only to be stored at a friend's until a home be found, and I have known such cases. Gardeners, if you are single do as you like; but if you are married remember the poor wife's feelings and how miserable little children are when moved about or in small lodgings.

Lastly, a word to amateurs. I know your feelings well; your disappointments in a bad season, your rejoicings in a good one. What delight is given you as you stroll round your garden and things seem promising! I expect a good season this year for us, but if my expectations be not altogether fulfilled I will still hum Tennyson's lines—

*I'll take the showers as they fall,
I will not vex my bosom;
Enough, if at the end of all
A little garden blossom."

I counsel you to do the same. To each and all readers, on this the fourteenth time of writing the opening piece of the annual volume, I wish a truly

HAPPY NEW YEAR,

—WILTSHIRE RECTOR.

CAMELLIAS AND AZALEAS IN DECEMBER.

I BEG to thank your contributor "COUNTRYMAN" for his account of the plants he saw in bloom at "Veitch's," and a description of the midwinter flowers in such an unique establishment cannot fail to be generally interesting and instructive.

"COUNTRYMAN'S" remarks about the scarcity of flowers in December and of Azaleas and Camellias being late flowers, lead me to suggest that it is not the fault of these two charming plants if they are not made to open their blooms long before December, and at a time when they look so charming and last twice as long in flower as they do after the turn of the day and in spring. There is no difficulty whatever in commencing the blooming season of these two favourite flowers early in October; at least, such has been my experience. All that is necessary is a proper selection of sorts and the application of an increased temperature at the beginning of the year to cause them to make their growth and set their buds early. This they soon get into the habit of doing without much extra forcing. They are plants, more especially the Camellia, that, as most people know, do not bear hard forcing to bring them into flower in autumn, but they expand very freely in the autumn if they are caused to mature their growth and set their buds early in summer.

I have had Camellias in bloom by the first week of October as a regular thing, and the same plants have continued blooming till February, individual blooms lasting more than double the time, either on the plants or when cut, than they do in spring. This takes place without any fire heat, except just keeping the temperature about 45° at night in cold weather. The varieties that come the most easily into this habit I find to be just the two best Camellias for general purposes—namely, *Alba plena* and *Imbricata*. To these may be added Chandler's *Elegans* and *Jubilee*. Doubtless there are others that I have not tried that are equally useful for this purpose.

Of Azaleas I find President Van den Hecke came into bloom in October without much more heat than has been referred to in the case of Camellias. The same may be said of Charles Leriens, a most beautiful semidouble rosy crimson flower; A. Borsig is also easily flowered thus early, and being a beautiful semidouble white is most acceptable for cutting and wiring for bouquets; as also is *Souvenir du Prince Albert*, a most lively rosy peach broadly margined with white. Besides these an excellent variety, *Iveryana*, can easily be had in full beauty in November; indeed, I have frequently had this variety in full flower in October. Then there are *Vittata* and its varieties, and one or two varieties of *Punctulata*, and *Roi de Leopold*, an excellent deep rosy crimson flower, all of which are available for the "dull time."

Referring to Camellias and to some remarks on the propriety or otherwise of not shading them when making their growth, I

may allude to a collection of healthy Camellias and exceedingly well bloomed that I had charge of for several seasons in the large conservatory at Wrotham Park somewhere about thirty years ago. These were planted out in a curvilinear-roofed structure of iron and glass, and consequently very light. The Camellias in question were never shaded, but had the full force of the sun the whole spring and summer. The foliage was remarkable for its size, dark green colour, and substance. I have never seen such floriferous Camellias since; and one plant of *Reticulata*, generally a straggling grower, was perhaps the most remarkable of all for its compact growth, immense leaves, and still more immense blooms borne in great profusion. The plant was 14 feet high, and formed a beautiful pyramid. These plants were, though never shaded, abundantly supplied with water, of which they took almost unlimited supplies in the growing season. There is this to be said of these plants and their exposure to so much sun, that they did not make their wood and foliage early, and consequently it was made under strong light, and was therefore all the better able to stand the brightness of the height of summer, apparently with advantage.

It is scarcely necessary to remark that Camellias to flower in winter and that grow freely in February would suffer if not shaded when the bright sunshine of May overtook them.—D. THOMSON, *Drumlanrig Gardens*.

GOOD RESOLUTIONS FOR THE NEW YEAR.

WITH the opening year stirring thoughts come crowding upon the minds of everyone whose life has a purpose and plan. Another span of time lays before us in no vague or indistinct manner. Clearly defined are its boundaries—months, days, weeks, hours, minutes are all placed clearly before us in calendars of all sorts; and while we look at their duration well indeed will it be for us if we realise the full value of an entire year and resolve to turn it to better account than any of the years that are gone. In the calm quiet last hours of the old year we were able to trace to its source the cause of many a failure, aye, and of many a success too, and to resolve that the outcome of past experience and the knowledge gained as much by failures, perhaps more than by success, should lead to better results in future. Such, at least, should be the end and aim of our efforts, and so will we qualify our resolutions, for it is not given to mortals to command success, but it is their undoubted duty to put forth every effort to ensure it.

Such reasoning applies to all classes—all callings, but it is especially intended here to bear upon gardeners and their duties, and it is hoped that it will lead to many an useful train of thought, many a good resolution, many an earnest effort; nor shall I be far wrong if I imagine the cogitations of those good men and true for whom I write to take some such tone as this:—"I am resolved to effect some improvement in every department. Advantage shall be taken of favourable weather to push on shrubbery and lawn work; to eradicate blemishes, such as overcrowding, uneven surfaces, faulty curves, bad walks, ragged or worn-out verges or edgings; to re-arrange and make trim climbing plants, to renovate old or sickly Roses with fresh soil and manure, and to impart and maintain a trim neat aspect to every part of the garden. In the kitchen garden the soil shall have my especial care and close attention, knowing as I do that upon its condition successful cropping very much depends. Not an inch of it shall remain undug after a crop is cleared from it, but it shall be broken-up and left to the wholesome sweetening influence of wind, frost, rain and sun till it is required for another crop. Solid manure shall be applied with no sparing hand when the ground is dug, and sewage or any liquid manure shall be poured upon it when crops are in full growth and the young roots are ready to feed upon such rich juicy fare, to the immense benefit of every part of the growth above ground. I will give particular attention to sowing seeds well and at the right time, to thinning and transplanting seedlings, and to maintain a full supply and constant succession of each sort of vegetable in its season. It matters not to me if the family is likely to be absent from home; my duty is to have an ample store of vegetables ready at all times, and I will do so as well as I can.

"In the fruit garden I will strive to give full attention to pruning and training, to keep branches well apart for the admittance of light and air, to have the branches furnished with plenty of strong spurs, and to make every tree a model of its kind as well as a prolific bearer of fine fruit. Any weakly trees shall be lifted and replanted in fresh rich whole-

some soil. Those which show traces of canker shall be root-pruned and have a rich surface-dressing to attract the roots from the cold subsoil, which is the probable cause of the evil. In the vineries I will strive for great cleanliness in the houses as well as in the Vines. I will give the borders rich surface-dressings of manure to attract and feed the roots; I will practise neither very close pruning nor pinching of the branches, and will neither have crowded growth nor overcropping. In the Peach houses I will endeavour to secure strong growth, foliage that is perfectly clean and healthy, a border of rich sound loam, and a free circulation of air, with the exclusion of cold winds in spring. In the Pine houses I hope to keep the plants quite clean, to secure an ample supply of bottom heat, and to have due care taken to avoid root-scorching or mischievous watering. All plants in pots shall have neither dirty foliage nor starved roots, one or the other of these evils being usually the cause of subsequent disease and failure. I will keep no worthless or sickly plants in the plant houses, and will confine my efforts to the culture of a selection of really useful plants rather than waste my time and strength upon a collection of curiosities.

"Such labour power as is placed at my disposal shall be turned to the best account, and in order to do this I will attend closely to its supervision myself, knowing as I do that—

'He that by the plough would thrive,
Himself must either hold or drive.'

While claiming the privilege of receiving and paying occasional visits to my brother gardeners for useful discussion and social intercourse, I will take especial care that its exercise shall not interfere with the due performance of my duties or cause the slightest annoyance to my employers; and if I succeed, as I hope to do, in making the garden more beautiful and the crops more abundant and fine than my neighbours, I will not forget that it is for the especial pleasure and benefit of those whom I serve that this is done, and not for the public."

If such thoughts are only followed by prompt action and persevering efforts they will surely lead to success. Let us not, therefore, fail to remember that resolution means firmness of purpose, fixed determination, constancy.—E. LUCKHURST.

JOTTINGS ABOUT ROSES.

UNDER this head you published in your issue of November 29th some remarks which, for the sake of the Rose-growing community of the district from where they emanate, can scarcely be expected to pass unchallenged. Your correspondent commences by descanting on the folly of travelling over the old and beaten path, and thereupon puts us in possession of a piece of information that has been before us for the hundredth time—that is, that Rose elections for exhibitions are misleading to people who are inclined to grow only what may be termed good garden Roses. Here your correspondent's originality is at fault; but he may, I think, lay claim to having propounded a new theory when he informs that Marie Baumann and Alfred Colomb are not desirable Roses for the purpose just named. For the sake of intending purchasers in the district of Chester-le-Street, and for the information of your correspondent, I may state that at three or four places within a mile or so of Red Rose Vineries I have seen these two Roses growing and blooming as well as any Rose could be desired to do. Further, I might say that Alfred Colomb, instead of having his smiles obscured or assuming a careworn or stunted appearance, the reverse is the case: his smiles beam forth beautifully and often, and his growths are strong and healthy. These desirable features in Alfred are not to be attained by one season's trial of it. A gentleman here who grows Roses well told me some years ago that he did not care for Alfred Colomb for the same reasons that your correspondent gives; but since then he has grown it on its own roots, and it is now a very great favourite with him.

As to your correspondent's selected dozen I would like to make a few remarks. Certainly Baronne de Rothschild is a superb Rose and generally does well here; so does Charles Lefebvre, which I consider a most satisfactory Rose and one that ought to be included in every order for a dozen. Your correspondent attaches the condition to these two Roses—viz., that they must be in thriving condition, a remark which holds good in the case of every Rose in cultivation, and one might fairly say in the case of every flower. The Duke of Edinburgh is certainly a brilliant flower, but I think in ordering a dozen I should not include it. Général Jacqueminot is a most desir-

able Rose and ought to be grown in every garden where Roses are found, but most certainly not clad in the same coloured raiment that our North Durham hunt sports; if so, I would imagine that our nurserymen were imposing upon us in a degree not to be tolerated. Next in order Mr. Witherspoon places Gloire de Dijon; certainly it comes nearer to a perpetual-blooming Rose than any I am acquainted with, and its hardiness and vigorous habit make it a welcome addition to any collection where Roses are not grown for exhibition; but Mr. W. and I must agree to differ when he says it is unsurpassed for buds. Surely he has never seen that gem of Roses, in bud, Narcisse. What can be more exquisite than a bud of this splendid Tea, so delicate, so beautiful? John Hopper is next in order, and a rare Rose he is, growing well and blooming till December. Louis Van Houtte is, says your correspondent, a fine dark Rose: surely he might have passed some higher eulogium on such a superb Rose. I have taken a particular interest in this Rose, and from its robust habit and free-blooming qualities I have been highly satisfied with it, and should most certainly vote it in the first dozen either for exhibition or otherwise. Mdle. Eugénie Verdier, Marquise de Castellane, and Prince Camille de Rohan follow next: the latter is advocated as a button-hole Rose, and is voted to be the most satisfactory dark Rose we have. I would prefer Pierre Notting, much as I like the Prince. Princess Beatrice or Princess Louise are both Roses, in my opinion, which would bring disappointment to the beginner who does not exhibit. Sénateur Vaisse brings the dozen of Mr. Witherspoon's selection to an end, and he could most certainly not have ended with a better; it is a splendid autumnal Rose, and I have no doubt your correspondent has succeeded well with it.

In selecting a dozen good garden Roses why does your correspondent omit such Roses as Souvenir de la Malmaison and Mrs. Bosanquet? What matters it to the average cottager or amateur whether he grows Hybrid Perpetual, China, or Bourbon Roses, so long as he derives pleasure from them and can always, comparatively speaking, cut a flower? Mr. Witherspoon says that we have not a distinct striped Rose of the York-and-Lancaster stamp; what says he of the Beauty of Glazenwood, the new Hybrid Tea, and Cillet Parfait, and several other Gallica Roses?

For the information of Rose-growers and intending Rose-growers in the neighbourhood of Chester-le-Street I may state that the best collections of Roses in this district are to be seen at Mr. Marshall's, Old Gardens, Lambton Park; the gardens, Lumley Castle; and at South Hill; and all these collections are under the charge of old and practical rosarians, who, although not claiming to have grown Roses at the age of five or seven years, are well known to possess a thorough knowledge of this branch of their profession, and, furthermore, they are every one able and willing to give the best of information to beginners.

Although I am not a personal acquaintance of Mr. Witherspoon I am inclined to think, despite his assertion of having tended to Roses forty years ago, that his experience is exceeded by his enthusiasm; therefore I think that he ought to take particular care that his jottings are not calculated to mislead our friends and neighbours. Nothing is so disappointing to beginners, and nothing so much calculated to damp their ardour, as to procure goods that are altogether unsuitable to their wants or to their situations; therefore I would advise all your readers in this district to see the Roses grown at the abovenamed places and judge for themselves, or hear from the managers what to procure or what to avoid. I hope that Mr. Witherspoon will accept my remarks in the spirit in which they are given—that is, a friendly one.—T. CRAWFORD, Lambton.

MRS. PINCE'S BLACK MUSCAT GRAPE.

HAVING grown the above variety of Grape some few years, and also having been tolerably successful in its cultivation, I venture to give my experience for the benefit of intending planters. When it was sent out I obtained two Vines, which were planted with others, one being the Muscat Champion and two Lady Downe's. I found the Muscat Champion would not do with the others, as it ripened much earlier, so I rooted it out and put a Mrs. Pince in its place. Then I had left two late sorts, Lady Downe's I found very apt to scald, smaller in berry, and more stony than Mrs. Pince, neither did it keep so well with me, nor was it to be compared in flavour; so I rooted out Lady Downe's and planted two more Mrs. Pince, and I never regretted it, as the latter fully came up to my expectations, with only one drawback—grow it how I would, with heat or without it,

I never detected more than a very slight flavour of Muscat. This is also the opinion of other growers whom I know. It is a fine-flavoured, good-keeping Grape, and also very large in the bunch. I grew one bunch this year nearly 2 feet long, so that I was obliged to cut it much shorter to get it into my show box. The Vine is prolific and a tolerably good setter, but as a rule it does not colour well.

This year I was most successful as regards the colouring, the whole house from top to bottom having over a hundred bunches of fruit of a good black colour, as Dr. Hogg, who saw them, can testify. Well, the weather continued dark and cloudy, and in a fortnight, to my surprise, the colour began to disappear, and do what I would the berries nearly all became a foxy reddish purple; besides which, for the first time I found them difficult to keep. I cut several bunches and placed the stems in bottles, and have some still—all these retained their colour—and I sent some away this week that were quite black. With regard to those I cut for exhibition, owing to the uncertainty of the arrival of the trains on the South-Eastern Railway, I was obliged to cut them the day before the show. I did so, and put them in my box. When I opened it next day at the Royal Horticultural Society's Gardens at South Kensington I was most disagreeably surprised to find my fruit had nearly lost their colour, and what is most curious is that the Muscat Champion, boxed at the same time, was none the worse. So I take it that the loss of colour is peculiar to Mrs. Pince; still, for all this it is a good Grape, and in my opinion far before Lady Downe's in flavour. I have not found it do well with heat, and it has a better flavour without it when it is ripening its fruit. However, I have now done with it, having rooted it out, as I intend to grow early Grapes in the house it has occupied.

As most people are abusing the Duke of Buccleuch, and as I think I was one of the first to write about it, having tasted it at the Kelso Show, and then (and now) thinking very highly of it, I shall try it under two conditions of growth; one will be in a ground viney. I grew the Golden Champion fairly well in one, also the Muscat Champion. Everyone was against that Grape, and I have grown it some years in a hothouse, in a cold house, and a ground viney, and I consider it is one of the best Grapes I ever tasted, and worthy of all praise.

Venn's Muscat is the strongest grower I have, and has done well, the fruit colouring readily. I should like to hear about the Golden Queen from anyone who has grown it. I have seen it truly grand shown at South Kensington by Mr. Pearson. Has anyone succeeded as well with it?—HARRISON WEIR.

LANDSCAPE GARDENING.

ON December 13th "Notes on Landscape Gardening" were read at the Darlington Gardeners' Institute by Mr. Bowker, superintendent of cemeteries in Darlington, and from them the following is extracted.

In laying out gentlemen's grounds the situation of the house and the style and arrangement of the gardens must necessarily depend upon the extent and formation of the ground, its accessibility, surroundings, and the requirements of the proprietor. When any person wishes to make the most of a place it is best to consult a good landscape gardener and an architect together on the ground before the house is erected or even designed. On large estates, where there is plenty of scope, the best position for the mansion is on a well-elevated part of a southern slope. The general arrangement might then be as follows:—Front—terrace, walks, parterre, fountains, and park. One side—lawn, roserie, rockery, and walks leading to the park, orchard, and kitchen garden. Other side—conservatory, lawn planted with ornamental trees, and walks leading out to the grounds and to the park. Rear—kitchen garden, stables, and all places intended for work. All these should be hidden by planting. The carriage road and entrance will depend upon the means of access, but they should be hidden sufficiently to give privacy. Parks should always be separated from the gardens by a low ornamental wall or balustrade above a sunk fence, or by a bright evergreen hedge. Nothing looks more unsatisfactory than a well-kept lawn adjoining a park and only divided by railing. Water, when properly managed, always adds to the beauty of a place, whether it be in the form of a lake or a river. A lake should appear to take its form from the ground. The indentations should be bold and not too frequent. The margin is best varied by some parts being rugged, and others smooth grassy slopes. Islands should appear natural. The plants must be such as usually grow near water; a few planted to project over the water look well.

Great care and judgment should be exercised in choosing and arranging trees. It is advisable to notice those which thrive well in the locality, and select accordingly. Ornamental and flowering trees and shrubs are the most suitable to plant near the mansion. The plantations should contain both evergreen and deciduous trees. The evergreens give an appearance of warmth during winter, and the brightness and changing colour of the foliage of the deciduous trees give a pleasing variety in summer. Large and robust trees are the best for a park. Planting should not be done too regularly, either in groups or in single specimens. A few irregular plantations with detached trees scattered about are most natural. Spaces should be left for views. Openness makes a place look cheerful. Want of room often compels people to plant as they can; but when planting is done to hide something objectionable the purpose should not be too apparent. Suburban villas are mostly placed with their fronts to the public roads, but by carefully mounding and planting comparative seclusion may generally be secured. Many, however, are so arranged that the front of the house, the stables, and kitchen garden are exposed to public view.

Before commencing to lay out grounds of any extent a good working plan should be made, so that the work may proceed in a straightforward manner. It is very unsatisfactory to a proprietor to see his grounds cut up and then altered and altered until they get into something like a garden. Much valuable material is wasted in this way. The work of laying-out and planting may commence before the building when the ground is extensive enough. The roads may be roughly formed, and the soil from them used for the borders or other places where required. Some planting may also be done. In levelling for lawns the surface soil should be removed, the ground made even, and then re-covered with the soil previously taken off. If this is not attended to some places will be bare or brown, while others will grow luxuriant herbage. Also, when preparing beds or borders, soil should be used suitable for the plants intended to be put in. When planting, we should consider what the plants will be in the future. Trees intended to be permanent ought to be planted first, and the intervals filled up with common kinds. These latter will help to furnish the ground, shelter the better plants, and may be thinned out as necessary. A landscape gardener ought always to consider the future. The man who thinks of the present only does not deserve to be trusted with a place of importance.

THE APPLE-BLOOMING SEASON.

In the spring and early summer of the year now past I took a few notes of the time some of the Apple trees came into bloom, intending to observe the effect on the crop. Perhaps they may be interesting to some of your readers at the present time.

The blossoming period was unusually late, and the weather, notwithstanding the delay, by no means genial. Cold nights and boisterous winds were too frequent to suit the setting of the fruit. The following are the memoranda:—

May 7th. Apple trees coming into bloom; a few blossoms expanded on some pyramid trees of Lord Suffield, espalier trees of Keswick Codlin, and standard trees of Transparent Codlin, Gravenstein, and Alfriston. The first-mentioned the most forward.

May 16th. Trees mentioned above in full bloom.

May 19th. In full bloom espaliers Northern Spy and Worcester Pearmain; also standards of Sturmer Pippin. At the same date nearly in full bloom were standards of Cornish Gillyflower, Golden Harvey, King of the Pippins, Pearson's Plate, Red Juneating; and espaliers of Hawthornden. At this date not a single bloom expanded on Lemon Pippin.

May 27th. First bloom expanded on standard Lemon Pippin.

June 2nd. Lemon Pippin nearly in full bloom. The following low standards in full bloom: Acklam Russet and Winter Hawthornden. Lemon Pippin was not quite in full bloom till 9th of June.

In looking over the trees after the blooming period was over the prospect of a crop on the Lord Suffield appeared very middling, but the final result was better than expected. There was a moderate crop, but the fineness in size partly made up for the smallness of number. There was a good crop on the Keswick Codlins and Hawthornden. There was a good crop on Transparent Codlin and Alfriston—very useful Apples, neither of which I should like to be without. The crop on Gravenstein was middling; I do not consider it a very good cropper. Those in full bloom May 19th were a fair crop; but

the largest crop of all was on the tree which was last in bloom—the Lemon Pippin. The tree was crowded on every branch like ropes of Onions, and had to be tied up in every direction with tarred cord and supported by two or three props. It is not a large tree, but has a great many branches, and I gathered more than a sack of fruit, which is most useful, as they are keeping better than most of the other Apples.

In observing the Apple bloom last year there was one circumstance which struck me as unusual, and that was that the Hawthornden was about ten days later than the Keswick Codlin. Unless I have been mistaken, there is generally only a difference of two or three days. I must observe this next blooming-time.

I think the produce to be obtained in certain parts of the country from fruit trees may be much increased by selecting varieties suited to the soil and climate. Some appear to be much more hardy than others, and some are well suited for espaliers; the latter mode of training is the one I should follow in a large garden where fruit is required every year. I should select a quarter of an acre of ground in a square, and on all sides of the square plant a hedge of *Arbor-Vitæ*, Hornbeam, or some other shrub which could be kept as a neat screen to keep off the cold winds, and if an acre were taken I should have four squares. The Apples I should plant would be Lord Suffield, Hawthornden, Keswick Codlin, &c.; these well managed would not fail more than once in ten years in a suitable soil unless the situation was very exposed, and in this way you would scarcely ever be without Apples. Cornish Gilliflower is a good Apple, but too delicate for this part of the country. I have a standard tree of it, but there was only a solitary Apple this year, and Gravenstein was not much better. Whether a market gardener planted these two Apples, or such as King of the Pippins and Pearson's Plate, would make all the difference between failure and success.—AMATEUR, *Cirencester*.

ARRANGEMENT AND CULTURE OF ROSES.

DURING the past season I have been into a number of gardens both large and small, and one thing strikes me, and that is the muddling way in which Roses are grown. Roses are pleasing wherever placed, but I should like to see my fellow amateurs give more attention to the Rose garden or bed. Why not have something artistic instead of a hundred plants here and a hundred there all over the place?

The following is a diagram of my Rose bed placed in a wing of my garden. *a*, Gravel path; *B*, centre bed; *c*, horseshoe ring.

Fig. 1.

The centre bed is large enough to hold three hundred Roses planted 4 feet apart. I have standards in the middle, then dwarf standards, and the outer rings dwarfs. All round the horseshoe I have standards, and dwarfs in front, also planted 4 feet apart: this takes about another three hundred. The effect of this arrangement in June is very striking. The horseshoe ring, according to my idea, is better than if continued all round, as by standing in front we obtain a grand view of the whole. This plan can be enlarged or diminished according to fancy or space. It has the advantage of being ornamental and practical. Manure to any amount can be given, and Roses grown either for exhibition or decoration.

A word or two about soils. For heavy clay there is nothing so good as plenty of unslacked lime dug-in two months before

planting; it sweetens the soil and keeps it open and friable, and enables sour wet ground to assimilate manure. Double-trench the ground, and mix the lime with stable manure; let it lie for two or three weeks, then dig well together, and the result will be as good a soil for Roses as can be desired.

For light soils cow manure is the best; it retains moisture, and, if given liberally, after a season or two makes the ground sticky and nourishing. In fact, for all soils except clay there is nothing like cow manure for Roses; it heightens the colour, darkens and brightens the foliage, and keeps the ground cool.

Lastly, plant well away from large trees. Use the syringe very freely. Never water, for it induces mildew, especially after a hot day (I am open to correction on this point). Do not prune too closely; thin out unsparingly, taking great care to cut out all dead and unhealthy wood; let the air well into the plant. Do all the work possible yourself, and learn from experience; and although the first season or two may turn out utter failures, in the end a prize at the National will recompense all heartburnings.—AN OLD ROSE-GROWER.

EARLY-FLOWERING CHRYSANTHEMUMS.

YOUR correspondent, Mr. F. Freeman, gives a list of thirty early-flowering Chrysanthemums, and states that he wishes to increase his collection. I think that there are several more Pompons that he might add to his list and also some large-flowering varieties, and I recommend him to add the following—Mrs. G. Rundle, George Glenn, Golden Beverley, White Beverley, and also the three *Cedo Nullis* and *Mdlle. Marthé*. If he would like Japanese varieties I would recommend him to have Elaine and James Salter.—A GROWER OF FORTY VARIETIES.

THE APPLE TREE IN THE PLEASURE GROUNDS.

THE Apple tree is not grown to such an extent in this country as it ought to be, nor as it might be, for the price of Apples at the present time is a proof that the demand is greater than the supply. Thousands of bushels are sent to this country from the Continent and from America, and the quantity and quality yearly increase. That beautiful kind called the Newtown Pippin, which is now to be seen in almost every fruiterer's shop window, is imported from America.

Of all hardy fruits the Apple is the most easily cultivated, and we may conclude from that that the climate of England is agreeable to its constitution, and there is no reason why this useful fruit, which is in so much request in every household, should not be more extensively grown.

I should like to see Apples in more general use as ornamental trees, and I cannot understand why they are not more frequently planted in places of moderate or even limited extent, such as in the gardens of suburban and villa residences, by intermixing them with shrubs, for it may be said with truth that there are few objects more beautiful than an Apple tree in full bloom. It would add greatly to the charms of the gardens and residences during the spring and early summer months, and afford in autumn a supply of valuable fruits in places where there is generally a want of it. There is scarcely an article of vegetable food more widely useful and more universally esteemed; and no wonder, for an Apple pie or tart are amongst the most wholesome food that can be placed on the table, and for dessert ripe Apples are equally enjoyable and healthful.

In one respect the gardens of the ancients surpassed our own. They did not think a beautiful-blossomed tree unfit for the pleasure grounds or flower garden merely because it produced rich juicy fruit. Now-a-days it rarely happens that Apple trees are planted in a position where their beauty can be appreciated and enjoyed, as would be the case in a villa garden, and those who would like to have their shrubberies made additionally attractive by the gradations of the different shades of colour should plant Apple trees for producing beautiful blossom in spring and rich golden fruit in autumn.

The following varieties I have proved excellent for dessert and culinary purposes, and they yield a supply over a long period of the year. Those marked with an asterisk are suitable for both kitchen and dessert use:—

DESSERT.—*Blenheim Pippin, October-March; *Boston Russet, December-April; Cockle Pippin, January-April; Cornish Gilliflower, November-May; *Cox's Orange Pippin, October-February; *Golden Reinette, November-March; Franklin's Golden Pippin, November-March; Kerry Pippin, September-October; Margil, November-March; Old Nonpareil,

January-May; *Ribston Pippin, November-March; *Reinette du Canada, November-April.

KITCHEN.—Alfriston, November-April; Beauty of Kent, November-April; Golden Noble, October-January; Gravenstein, October-December; Hawthornden, October-January; Keswick Codlin, September-November; Nonesuch, September-October; New Hawthornden, November-January; Northern Greening, December-March; Waltham Abbey Seedling, September-January; Winter Greening, November-May; Bedfordshire Foundling, December-April.—NATHAN COLE.

SERVICEABLE GRAPES.

WE have now a very extensive array of Grapes. Nearly one and a half hundred varieties or kinds are described in Dr. Hogg's "Fruit Manual," and the lists of nurserymen are very much more prolific in Grapes than they were a few years ago. New (or alleged new) varieties have made their appearance, and some, though backed up by first-class certificates, have proved of questionable merit, it being doubtful if any new varieties are equal to Black Hamburg and Muscat of Alexandria for general purposes. I have no hesitation in saying that for a majority of growers they are the Grapes *par excellence*. Go where we may we find a preponderance of Black Hamburg; it is the most prominent of black Grapes. The Muscat of Alexandria is grown by everyone commanding heat; it, next to the Black Hamburg, is the most extensively cultivated Grape. Not the least that can be said in the favour of those Grapes is that they succeed with everyone, if able to grow a Grape at all. It may be urged that the Muscat of Alexandria is a bad setter, but compare it in that respect with some of the newer kinds grown in the same house and we shall find that there is not nearly so bad a setting nor so many stoneless berries in the Muscat of Alexandria as the others, Mrs. Pince and Black Muscat being great sinners in that respect.

But much as I like Black Hamburg and Muscat of Alexandria they cannot be depended upon for a supply of Grapes from December to April. During some seasons they keep very well up to Christmas, but not always, and I do not think it judicious to rely upon them after November; therefore we are under the necessity of a third, and that, as I have found it, is Lady Downe's. I have seen fruit of this Grape hanging quite fresh in April, while it is well known that Grapes keep quite as well cut with a portion of shoot inserted in water in a dry room as on the Vines; indeed, very much better than in a leaky vinery. With the three kinds—viz., Black Hamburg, Muscat of Alexandria, and Lady Downe's—we need have no fear of not maintaining a supply of Grapes the year round, and it may be accomplished by a house of Black Hamburg, to ripen in late April or early May; a second of Muscat of Alexandria, to ripen in June or early July, having a few Black Hamburg in the same house, which will be ripe a month earlier than the Muscats; and a third house of Muscat of Alexandria and Lady Downe's, planted alternately, to ripen in September, the Muscat being good until near Christmas, sometimes later, when Lady Downe's will come in and continue until May.

Another such trio is not to be found in Grapes. Why have more kinds? Variety is wanted. Many know not what it means. A vinery planted with as many Vines of different kinds as the house can accommodate instead of but one, or at most two kinds, means, as I have invariably seen and experienced, some success with no little failure. My advice to beginners is—Do not plant a dozen sorts of Grapes if one will serve the purpose intended, unless it be specially proposed by the proprietor. Quantity and quality are combined in the sorts mentioned, and they generally afford satisfaction alike to grower and consumer.

Variety being requested, and I confess to admitting its charms, let it be sought in kinds that are likely to afford satisfactory results, inasmuch as there is no need to admit doubtful kinds, we having so many really good tried Grapes awaiting acceptance. I may note a few for different times of the year, and shall endeavour to name as few as possible consistent with the object in view.

Early vinery—Mill Hill Hamburg, Black Hamburg, and Black Muscat (Muscat Hamburg) worked on Black Hamburg. Of whites—White Frontignan, Golden Hamburg, Buckland Sweetwater, and Foster's Seedling—representatives of the Hamburg, Muscat, Frontignan, Sweetwater, and Muscadine Grapes. A house of those kinds may be forced to afford Grapes in April onward, they being equally select for ripening in June.

Second vinery or mid-season—Black Hamburg, Black Prince, Frankenthal, Madresfield Court, Muscat Troveren, and Foster's Seedling. Muscat of Alexandria is at this season indispensable. It is best grown in a house or division by itself, having a good black companion in Mrs. Pince and Black Muscat of Alexandria.

Late vinery—Alicante, Lady Downe's, Gros Colman, West's St. Peter's, Bowood Muscat, White Tokay, Mrs. Pince, Gros Guillaume, and Trebbiano. Calabrian Raisin and Syrian may be added if more whites are desired. A house of Gros Colman, Trebbiano, Gros Guillaume, and Syrian would produce a sensation, but the great desideratum is a suitable black companion for Muscat of Alexandria, there being none at all worthy of the position except Black Hamburg, they unfortunately in the same house not ripening together; also a white companion is equally wanted for Lady Downe's.—A. G. P.

VEGETABLE CULTURE.

CHAP. I.—INTRODUCTION.

CERTAINLY no apology and very few words are needed to introduce a subject the importance of which is so apparent as vegetable culture. As articles of wholesome diet good vegetables are more necessary than any other kind of food to the human being. Their cultivation is universally practised, but in many instances their successful cultivation is very imperfectly understood, and, what is equally to be regretted, there are many kinds of vegetables excellent for food that few excepting qualified gardeners know either how to grow properly or how to use, although requirements in both respects may be extremely simple. Taking this into consideration, and also knowing how eagerly information concerning successful vegetable culture is sought after, I have been induced to begin a series of communications on this subject which will simply, fully, and practically detail the cultivation of every description of vegetable capable of being converted into profitable food. At the same time the best mode of cooking will be briefly appended when it is deemed necessary to do so.

VEGETABLE GARDEN FORMATION.

This is a matter which must be provided for as well as circumstances will permit. As it is impossible to describe every kind of vegetable garden which might be made, I will just give a few details of an ordinary one which will suit general requirements, and which may be applied to a piece of ground of any extent. The best form for a vegetable garden is square; but at the same time when this cannot be secured long strips or even triangular pieces of ground answer the purpose very well. Situation is of greater importance than shape. It is never desirable to have a vegetable garden on a high exposed place nor yet in a very low position, but the latter is to be preferred to the former, because many vegetable crops are extremely easily injured by exposure to wind and drought, both of which they are subjected to when elevated.

For obvious reasons the vegetable garden should always be convenient to the house, but as invisible from it as possible. Where no plantation or elevated ground conceals it, let it always be at the back and never at the front of the house. A plantation shelter from the north is a great advantage, but the exposure to the south, east, and west should be free and open, excepting where the situation is greatly exposed to cutting east or west winds, when a screen of trees a short distance from the garden will be found very beneficial. The aspect, too, must be taken into consideration; for although the ground may have the desired exposure and shelter, if the aspect is not correspondingly good the other advantages lose their value. The ground should slope as near south-east as possible, or it may be level, but it must not slope to the north. Its extent must be regulated by the requirements of those to be supplied with vegetables; but any garden above one acre in extent should be surrounded by a red brick wall 9 inches thick and from 10 to 12 feet high. Many gardens are surrounded by walls much lower than this, but they are neither the best nor most profitable for fruit-tree culture. Large gardens are generally surrounded by walls of an uniform height, but in small gardens the south wall may be a few feet lower than the others. The basement of the wall should consist of stone up to the ground level, and the bricks which follow this must be substantially and neatly built in, and the coping should be of dressed freestone placed so as to project about 3 inches on each side.

Small gardens must never be too much divided by walks. A border, however, should run round the whole length of the

wall, terminating in a walk. The width of this walk, and the border as well, should depend on the extent of the garden. In an enclosure of one acre the walks should not be more than 6 feet and the border 12 feet. In a garden six or eight acres in extent both walks and borders may be double that width. Apart from the walk just mentioned it is necessary to have divisional walks. In small gardens a walk should run through from the centre of the north wall to the centre of the south wall, and the same from east to west. This will leave four quarters of vegetable ground. Larger gardens may have two walks running from north to south in the place of one in the centre. Where walks cross and meet for ornament there may be a circle formed, and for convenience there may be a round stone tank built to hold water, a good supply of which must be brought into the garden where it does not exist.

It is hardly necessary to point out what kind of soil should be secured in a vegetable garden, as this is included with other circumstances, about many of which there is little choice. A good mellow loam from 18 inches to 2 feet deep, and not too retentive, is more suitable than any other kind of soil. In preparing this for cultivation dig all the good soil out of the walks and spread it over the vegetable-growing patches. Then trench these to the depth of 2½ feet; gather all the stones from the soil, and those not required to fill up the bottom of the walks with should be laid at the bottom of the trench to act as drainage where this does not naturally occur. In very wet soils and in low situations drains 3 feet deep should be laid in every 12 yards to fall into a main out at the lowest part of the garden. In vegetable gardens stone or tile edgings are the most desirable, as they give no harbour to slugs or other pests. The glass structures should consist of one or two good forcing pits and a number of large and small frames, which may be placed in any position not hidden from the sun. A Mushroom house should also form an indispensable part of every good vegetable garden. Many little details which may be found necessary are omitted here, but all the most important points are included and may be applied with a little addition or reduction according to circumstances.

THE POTATO.

This vegetable claims our first consideration, and the first attention of everyone who has a kitchen garden. It has little or nothing to do with future cultivation to write a long history of the introduction of this and other vegetables into this country, consequently few remarks will be devoted to this head; but too much credit cannot be bestowed on those who have improved the originals of many vegetables into such palatable and wholesome food. The Potato was introduced from Virginia to England by Sir Walter Raleigh in 1586. Since then its cultivation gradually extended until it became a staple article of food, and it has for years been regarded as second in importance to few crops in the country. The dreadful disease, the effects of which, if not the cause, are so well known, has for years proved very disastrous to the crops; and although much has been written and many things invented to stay its progress or stamp it out altogether, the past season has proved in a very undeniable manner that every line that has been written, and every article that has been invented to prevent it, have completely failed. Let anyone look at the Potato crops generally of 1877, and then prove this to be incorrect. That the disease may be modified by soil and situation I grant, but that it will be influenced by the weather is where everyone must feel their weakness of even modifying it. Passing to cultural observations I will first refer to

Forcing the Potato.—The success attending this mode of culture should induce its more general adoption. It is, however, only in few gardens where the Potato can be forced very early and in sufficient quantity to give a large supply for any length of time; but a considerable quantity may be had from a very small space under glass, and a few even so produced assist to complete an all-the-year-round supply, which is more desired in the Potato than any other vegetable, and is easier secured than in most others, as the Potato keeps so well for such a length of time. Where profit and pleasure are aimed at few crops pay better for marketing than early Potatoes. We always manage to have a few dishes from pots early in January, but our chief supply begins from the middle of April onwards. To have them ready at that time they must be planted during the first or second week in January, and hot dung or leaves, or both mixed together, must be placed in a pit or frame to the depth of 3 feet, then above this must be spread 1 foot of soil. When this has been done

the tubers may be planted 10 inches between the rows and 6 inches between the sets. After planting the glass lights are put on, but any kind of board shutter will do until the shoots are above the soil. Air must be admitted on fine days, and coverings must be employed during the time of hard frost. Water is seldom needed until the growth is considerably advanced, as much moisture comes from the fermenting material at first. When the sets are planted 6 inches below the surface they require no earthing-up. About the beginning of April when the weather is mild the lights are taken off altogether. Myatt's Prolific Ashleaf and Rivers's Royal Ashleaf are two of the best varieties for forcing, as they do not produce many stems but a great crop at the root, and they are excellent in flavour.—A KITCHEN GARDENER.

ZINC LABELS FOR ROSES.

THIS is a question I should like to see discussed in your Journal. It is now some years since I was led to discard zinc labels and copper wire, the shoots dying on which they were fastened, although in every case I was careful not to injure the bark by fastening too tight. I have since used wooden pegs about 15 inches long and about 2 inches wide driven into the ground, the names of the Roses being written upon white paint while the paint was wet. This seems to answer very well, but has several drawbacks, chief of which is that the label so soon looks dirty, particularly if you mulch and the season is wet.—J. BROWN.

VINE BORDERS.

I WAS very pleased to see at page 495 that the notes on Vines which I have sent you from time to time have merited the attention of such a good gardener as Mr. Taylor. As a rule I think his brief practical remarks are highly worthy of being adopted, but I cannot agree with either the instructions, constructions, or corrections which he has submitted on Vine borders. If inside Vine borders have any advantage at all, which I am very doubtful about, it is only in the case of early Vines, and then the benefit is only in assisting the Vines into growth, and not in securing their permanent well-being. It was proved to my satisfaction long previous to October 11th that inside Vine borders were inferior to outside borders. I am not the only one, I know, who have their minds fully made up on this point, and they have had opportunities of observing and gaining experience that any ordinary Grape-grower would not acquire in a lifetime.

Mr. Taylor thinks that to keep the border so dry as to cause the leaves to shrivel is the "description of Vines under decidedly bad management." In some instances it might be, but not in all; and that this is the treatment to which six inside borders out of every ten are subjected to I have had pretty good chances of knowing. Mr. Taylor cites his own Vines as examples of what may be done by inside borders, but Vines under his management cannot be taken as representing the ordinary and general standard of Vine-growing in this country. But what would Mr. Taylor say to a gardener, with knowledge of Vine-growing corresponding with his own, being compelled to keep the inside border "nearly dust dry?" Apart from growing the fruit there is the keeping of it to take into consideration, and Grapes cannot be preserved on the Vines throughout the winter with the surface of the border saturated and continually charging the atmosphere with moisture.

Respecting the Vine-border composts I thought the different quantities of the various ingredients would be clearly understood when I stated that the body of the compost should consist of loam, with one-third of decayed cowdung, &c., added. No person could rightly understand that by adding one-third to a whole it was applying it in equal parts. But to make matters plain, take three cartloads of loam, add one of cowdung, and another of wood ashes, and a bushel of smashed bones to every cartload of the whole. This is the mixture which I recommended, which I still adhere to, and in which I have grown as fine Vines as any I ever remember seeing. Just a word on Mr. Taylor's recommended mixture for growing Vines in. Soil naturally suitable for growing Vines will grow them for a time without the introduction of any artificial ingredients; but suitable or unsuitable, I am quite at a loss to understand what benefit Vines would ever derive from one bushel of bones mixed in fifteen cartloads of loam. The pieces of bone that would go to each barrowload of loam at this rate might be counted on the fingers of one hand.

It is well known that about towns, where there are so many vineries, and in many country districts as well, proper Vine-growing soil is most difficult to be had, and anything approaching the right material can only be secured by adding liberal quantities of other ingredients. Mr. Taylor, I fear, does not make enough of allowance for this, nor for the many who are deficient in other acquirements which he admittedly possesses.—A KITCHEN GARDENER.

THE ECONOMIC USES OF FLOWERS.—No. 1.

OF the various parts of plants used industrially the flower would seem to be that of least importance, and yet this enters more than would be at first supposed into commerce, and many flowers are of the greatest importance to the perfumer and dyer. Not to speak of the trade in cut flowers and flowering plants, and the extensive commerce carried on in these in great cities, and passing over a considerable branch of trade in what are known here as "Everlasting Flowers," and "Immortelles" on the Continent, an acre of which plants will yield 2 or 3 tons weight of tufts of flowers, realising from 12s. to 16s. per cwt. A few details may be given serving to illustrate the commercial value and various uses of flowers.

Among the most important products in a commercial point of view are Safflower, Saffron, Rose leaves, Lavender, Pyrethrum, Orange blossoms, Cassia flowers, Violets, Jasmine, Tuberose, and Camomile flowers.

Safflower, from the deep orange petals of the *Carthamus tinctorius*, is obtained in parts of southern Europe, India, and China, the latter being considered the best. The imports of Safflower into this country vary considerably, having reached as much as 32,000 cwt. in some years, but in the last two years our supplies have dropped to about 3000 cwt. The great centre for the use of this dye stuff appears to be Lyons, where it is employed to dye silks and satins.

We also import from 3000 to 5000 lbs. of extract of Safflower, worth from £1000 to £1700. The exports of Safflower from India exceed in value £100,000, and from China they are about the same amount, to say nothing of the local consumption in Asia and the produce in southern Europe.

Saffron is obtained from many countries, but the preparation is chiefly confined to France and Spain. The total value of the saffron produced annually is estimated to amount to one million sterling. About 30,000 flowers are required to produce 2 lbs. of fresh pistils, which when dried are reduced to one-fifth of that weight. Pereira says it takes nine flowers to make up a grain of marketable saffron, so that it would require no less than 4320 flowers to yield 1 oz. Some, again, assert that to produce 1 lb. of dry saffron 107,520 flowers are necessary, while others put the quantity as high as 203,920 flowers. According to Dumesnil, in the "Académie des Sciences," 7000 to 8000 flowers are required for yielding 17½ ozs. of fresh saffron, and this weight, as already stated, is reduced one-fifth by drying.

Our imports of saffron are, compared with its use on the Continent, not very large. They were:—

	lbs.	£
In 1867	9401	17,963
" 1868	26,048	50,198
" 1869	22,152	36,596
" 1870	43,980	95,890

The imports into this country have not been published since then. The largest quantity comes from Egypt (nearly half), then follow the supplies of Spain and France, varying in quantity according to crop. Judging by prices the Spanish would appear to be held in less estimation than formerly.

Very extensive Rose farms exist at Shiraz in Cashmere, at Ghazepore in India, at Adrianople in European Turkey, at Broussa and Usiak in Asiatic Turkey, and about Cairo and other parts of Egypt. It is said to have been the Princess Nour-Djihan who discovered, at the commencement of the sixteenth century, the essence of Roses in the empire of the Mogul, and received for this a necklace worth £3000. In 1611 the Sultan Ahmoud I. sprinkled the pavement and the interior of the new Kasbah with jets of Rose water. It is also said that Saladin, after the peace of Jerusalem in 1187, sprinkled the Mosque of Omar with Rose water from Damascus. The odoriferous Rose was formerly cultivated in the oasis of Fayoum, Middle Egypt, but the culture has been almost abandoned. The essence used locally there is now chiefly obtained from the ordinary Roses of the country, collected in spring in the gardens.

Experience has shown that for every ounce of attar of Roses 3000 lbs. of Rose leaves are required.

The yearly production of the districts in the province of Kezanlik is on an average 3500 lbs. Some years, however, the bushes are exceptionally prolific. Thus in 1866, 6000 lbs. were produced, but in 1872 only 1700 lbs. could be obtained. The war now raging in this district has, however, made sad havoc with the Rose gardens, and for a time destroyed the produce. The pure attar, at 30s. per ounce, yielded an income of £84,000 yearly to Roumania. Of Rose leaves we imported—

	lbs.	£
In 1867	8775	476
" 1868	5323	267
" 1869	6427	321
" 1870	5392	420

Since that year there has been no official return published.

The leaves are usually imported salted. 1 lb. of salt well mixed with 1 bushel of Roses (6 lbs.) converts them into a magma (pickle). As their primitive odour is preserved they can be distilled at any time, and produce as good Rose water as fresh Roses. The Provence Rose will yield in the second and third year from 1 to 200 bushels of Roses per acre. The Damask Rose is that chiefly cultivated for medicinal purposes. Just before the bud is about to open it is plucked, and the bottom of the bud is cut off. These cuttings are termed "Rose heels;" the top is preserved, either to make infusion of Roses or conserve of Roses.

M. Piver some time since published the following statistics of the flowers employed in perfumery annually produced in the department of the Alpes Maritimes:—

	Kilos.		Kilos.
Roses	904	Tuberose	18,200
Orange flowers	61,218	Cassia or Acacia	35
Jasmine	62,500	Violets	86

The Lavender fields in the London district cover about 500 acres, and the yield of essential oil varies from 15 to 30 lbs. weight per acre, according to the season or age of the plants.

The little bouquets of Violets which are generally sold in the streets of London are the produce of many acres of land at Mitcham and its neighbourhood. On one farm there are 16 acres of land under Violet culture. The two varieties of this flower principally grown are the Russian and the Giant. The first-named is darker in colour, the latter is the most fragrant. There are large Violet farms in the south of France, of more than 100 acres, near Nice.

Several species of Pyrethrum are grown in parts of Europe—*P. carneum*, *roseum*, &c.—for their flowers, which are very obnoxious to insects, and are sold when powdered under the name of Persian or Caucasian insect powder. In 1870 these flowers were exported from Rugosa to the value of £1104. That from the Caucasus is the best. The amount of this powder consumed annually in Russia is said to be about 500 tons. A quantity of these plants grown upon 18 square rods is estimated to furnish nearly 1 cwt. of powder, which is best preserved in closed vessels of glass. As generally sold the powder is very much adulterated and worthless, often mixed with Sumach. A good insect powder ought to stupefy a fly in one minute if four grains are sprinkled on it in a vial, and death should ensue in two or three minutes. Some of the commercial insect powders, however, require fifteen to thirty minutes to kill a fly.—P. L. SIMMONDS (in the *Chemist and Druggist*).

REVIEW OF NEW BOOK.

The Gardeners' Assistant, by ROBERT THOMPSON. Revised and Extended by THOMAS MOORE, F.L.S. London: Blackie and Sons, Paternoster Buildings.

A CURSORY perusal of this book enabled us to pronounce it "a sound and a splendid volume." It is sound because it is a record of the experience of a man of practical eminence, also because it contains chapters by other successful cultivators, such as Messrs. Douglas, Baines, McLellan, Burbidge, Gower, Baker, and others. It is also handsome in appearance by its general high finish, the excellence of the paper, the clearness of type, and the superiority of the coloured illustrations and numerous wood engravings. Yet while we have nothing but praise for its general appearance, we doubt the wisdom of so greatly enlarging it and rendering it an expensive work beyond the means of many whom the author intended to benefit. To thousands the volume will now be regarded as a luxury to be desired rather than an "assistant" easy to be obtained. We do not suggest that the additional matter is unnecessary, but,

on the contrary, we esteem much of it indispensable; our objection is to the retention of much that has become obsolete. We should have preferred that the work of excision had been much more thorough in order to have prevented disappointment, which cannot fail to be experienced by purchasers, who must now pay a very high price for much very commonplace, even useless matter. In a standard volume of such importance as this is nothing should be retained except what is really useful or instructive. In the matter of Peas varieties are retained and minutely described which are seldom if ever cultivated now, but which are extracted from seedsmen's lists. For example: at page 240 we find the Early Charlton Pea. There is no such variety now. It has been exploded many years ago, and nothing is left of it but the name. Early Charlton now simply means any common white Pea which anyone may go into Mark Lane on a market day and buy a hundred quarters of. No seedsman ever grows Early Charltons specially for the supply of his customers. The "Gardeners' Assistant," so far as the lists of vegetables are concerned, could not fail to bewilder those seeking for guidance rather than give them the aid they require, unless they were already as well taught as the teacher.

The lists and descriptions of stove and greenhouse plants are complete and excellent, but the selections given of varieties of such ever-changing plants as *Petunias*, *Pentstemons*, *Gloxinias*, *Zonal Pelargoniums*, &c., while being reliable now will in a year or two be superseded, and considering the cost of the volume, varieties so ephemeral cannot be said to occupy such valuable space profitably. Carpet bedding is introduced and coloured diagrams given, but we note in the list of green plants that the most popular and extensively planted of all, *Mentha Pulegium gibraltarium*, is omitted; perhaps, however, this plant may "go out of fashion" before another edition of the work is called for, still for the time being the omission renders the subject strikingly imperfect.

By way of rendering the volume more acceptable in reducing its bulk, and consequently its price, it is worthy of consideration as to whether the tedious and lengthy detailed calendar of operations could not be with advantage greatly condensed, or, indeed, entirely dispensed with. Similar but better, because more modern and serviceable, compilations are scattered broadcast by enterprising seedsmen. Cheap annuals are circulated by thousands which give fuller information of the same kind, and every section of the gardening press gives weekly instructions for the prosecution of every operation of gardening, which render an old calendar in a bulky volume superfluous. Since the calendar to which we refer was written great changes have taken place in the literature of gardening, and we think we know sufficient of the practical mind of the late Mr. Thompson to warrant us in supposing that he would have concurred, under the present circumstances, in the inadvisability of increasing the bulk and cost of a volume by the retention of fifty pages of matter, which we doubt not a majority of readers will consider might be very well omitted. Of the practical nature of the greater portion of the book we cannot speak too highly, and it is because we desire such sound and useful teaching be placed in the hands of everyone engaged in gardening operations that we have suggested a means of placing it within the reach of many who cannot become possessed of it in its present form.

We regret that a work so beautiful and costly should be marred by any blemish. At page 171 we find little Pixie Cabbage given as a distinct variety which it is, but in the same column it is given as a synonym of Atkins' Matchless. At page 249 the late Mr. Alfred Smee is spoken of as "Dr." Smee. Salwey Peach is called Salwey. No notice is taken of fruits of such excellence as Hale's Early Peach and Lord Napier Nectarine. The common name of Kentish Cob among Nuts is sought for in vain. The Fig Gros de Draguignan is spelt Draguignan. Oullins, which is the name of a place, is given as that of a person. Bavay is spelt with a. In the cut representing the inflorescence of the Walnut on page 483 there are no references to the description given on 482, leaving the reader without an "assistant" to tell him which are the male and which the female flowers. There are many more instances of careless editing, these being noticed at a mere glance through the volume; and we are amused at the pedantic way in which the old name of "hardy trees and shrubs" is converted into "hardy arboreal and shrubby plants."

It would have been as well if the source whence so many of the woodcuts were taken had been acknowledged. It is hardly fair to M. Du Breuil and M. Alphand that their beautiful

illustrations should have been so freely used without even the mention of their names, while the services of everybody who appears to have done however little to the work are "acknowledged with thankfulness."

BRUNSVIGIAS AND THEIR CULTURE.

ONE of the tribes of charming plants that secure our esteem and are worthy of extensive cultivation are the *Brunsvigias*. They are half-hardy bulbous plants, that can be grown under very favourable circumstances in the open border, but they must have all care to succeed with them out of doors. It is useless attempting to cultivate them outside in many places, as they are impatient of wet when in a matured state. They are said to be named after the noble house of Brunswick, and are natives of the Cape of Good Hope. Some of these plants are to be met with in cultivation here and there, but it is by no means of common occurrence. To cultivate them successfully in our variable climate they are best grown under glass in a warm greenhouse or cool stove. If we could have a hardy strain of these beautiful flowers I doubt not but they would become very popular.

To succeed with them in pots bulbs for single specimens should be potted 3 or 4 inches below the surface of the soil, consisting of good sandy loam and peat with a little well-decomposed manure, with knobs of charcoal and grit mixed together, taking care that the pots are efficiently drained. They should be potted moderately firm in the soil, and be placed in a light house and watered carefully. When fairly in growth they require a good supply of water until the flower scapes appear, and when they have repaid us by their magnificent blooms water should be gradually withheld until the growth has ripened-off. They can then be stored away in a warm dry place until they are again required for potting, as a period of rest is essential to success. Should it be desirable to have a display of these lovely flowers, four, five, or more bulbs may be placed in large pots. When so grown they produce a magnificent effect.

They are increased chiefly by offsets; with impregnation they may be increased by seed. In potting the offsets should be removed, and if required to increase the stock they may be potted into small pots and treated as the older bulbs. Those most commonly met with in cultivation are *Brunsvigia grandiflora*, *B. marginata*, *B. striata*, *B. multiflora*, and *B. ciliaris*. Others might be named which are worthy of the notice of the cultivators of those beautiful flowers that adorn our homes and the structures we love so well.—H.

NATIONAL AURICULA, CARNATION, AND PICOTEE SOCIETIES.

SOUTHERN SECTION.

At a general meeting of the subscribers and executives of these Societies, held on the 4th ult. in the Council Room of the Royal Horticultural Society, South Kensington, Thomas Moore, Esq., in the chair, audited balance sheets and lists of subscribers in each case were presented, read, and ordered to be printed for distribution, and resolutions as undernoted unanimously adopted—viz:—

1. That inasmuch as the causes which called the Southern Sections into existence remain in undiminished force, the Presidents, Vice-Presidents, Committees, and Hon. Secretary be requested to continue their functions.
2. That the subscribers be gratefully thanked for the handsome support accorded to the Committees, congratulated on the beautiful displays resulting therefrom on April 34th and July 18th respectively, and respectfully urged to continue their support for the following season.
3. That a copy of these resolutions be forwarded to each subscriber, with a form to be returned to the Hon. Secretary, stating the amount of subscription each subscriber will be pleased to accord to the Society.

In accordance with the latter resolution copies of the balance sheet and list of subscribers have been duly sent out, and on behalf of the Committee I shall gratefully esteem an early return of the form sent therewith, so that the Committee may proceed to the arrangement of the schedule of prizes for the Auricula Show fixed to be held in the Crystal Palace on Thursday, April 25th.—E. S. DODWELL, 11, Chatham Terrace, Larkhall Rise, Clapham, S.W.

HOLME LACY.—No. 2.

THE SEAT OF SIR HENRY SCUDAMORE STANHOPE, BART.

HAVING adverted to the beautiful park at Holme Lacy, the dressed grounds next demand attention. These are tolerably extensive, but they are chiefly noteworthy for their diversified and extremely picturesque character. In many, perhaps in most, gardens of an ornamental nature, some particular feature predominates. Fine terrace walks, broad smooth lawns, noble trees, evergreen masses, brilliant groups of bedding plants or

collections of hardy border flowers, prevail and constitute the primary feature. This is not so at Holme Lacy. Each of the features named is not only represented but is sufficiently prominent to attract notice, while the whole are balanced and blended so well as to form a picture singularly striking and complete.

An idea of the stateliness of the walks has been given. Their dimensions—north terrace walk 700 feet long and 45 feet wide, and a south walk 800 feet long by 30 feet wide—suggest that some open lawns and other accessories are required to afford relief to the great area of gravel. They are provided; and so far from the gravel appearing obtrusive the size of the walks is scarcely noticeable.

The entrance drive to the mansion is from the north through a pair of elaborate wrought-iron gates, whereon the armorial bearings of the family are displayed. The park is here treeless, and merges into a lawn of two acres similarly treeless: this is the north or archery lawn. The east lawn is also destitute of bed or tree, and extends to the park-like valley of the Wye, from which rises a range of tree-clad hills towering boldly and melting away in the misty distance. Nature was in a happy mood when this splendid eastern view was formed. The walks are not an inch too wide nor too long for such imposing surroundings. To have planted those lawns with trees would have detracted from the beauty of the distant landscape, which is here worthily and rightly regarded as the chief feature of attraction, while to have dotted them with flower beds would have been a still greater violation of the tenets of good taste. How often do we see the natural beauties and resources of a place so divided and diluted that not one imposing feature remains, instead of first ascertaining what that feature is and seeking to give it prominence by rendering the surroundings subservient to it.

The view from the south terrace is quite different. Immediately in front of the mansion is the Dutch garden with its broad sunken terraced glade as a central point, descending between walls of Yews to the valley and water scene. Parallel with this glade, and about 40 yards distant on either side of it, are two broad gravel walks also leading to the valley. The spaces between these walks and glade are lawns on which are some fine deciduous trees clustered with Mistletoe and towering from such masses of Yews as are seldom seen. The lawn between and under these Yews is kept in excellent order, which adds greatly to the general effect. On the open spaces next the walks are some choice specimen Conifers and clumps of the stately and elegant Grass *Arundo* *conspicua*, the towering silvery plumes of which are rendered additionally and charmingly conspicuous by the dense greenery of the Yews, which are here the chief feature; these, growing free and unchecked, possess a grandeur of their own, which is enhanced by a very few flowering shrubs irregularly interspersed and the trees and Grasses mentioned. Two trees here, however, demand special mention. One of them is common enough of its kind—the Pinaster, but a specimen of such imposing dimensions is rarely seen. It has been planted on a square elevated platform of lawn, and is a noble timber tree commanding the attention of every passer-by. The other tree is still more rare; it is a remarkable specimen of the North American *Planera* *Richardi*, which is probably unequalled in England. The splendid trunk, smooth and round, widens and divides into more than twenty nearly upright branches, each of great size, which form a magnificent oval-shaped head fully 80 feet high and of proportionate width. It is a marvellous specimen of a beautiful and rare tree. If a finer example is to be seen in Britain I should be glad to know where it is growing.

Such is the view from the eastern end of the south terrace walk. Let us now traverse the walk westward, pausing—as the stranger is compelled to pause—to inspect and endeavour to comprehend the details of a picture that is altogether unique. When a certain Doctor, who has “something to do” with the Journal, returned from a visit to Holme Lacy, he was so impressed with the remarkable beauty of this terrace that “nothing would do” but that I must see it too. “Go,” he said, “it will do you good.” I went, therefore, “by the Doctor’s orders;” but, much as I enjoyed the visit, I almost wish in the interests of my readers that I had remained at home. I will endeavour, however, to describe the scene of nature and art which are here so effectively blended. On the right of the walk is a narrow lawn, having a background of shrubs. Near the front of the lawn are single specimens of variegated Hollies, choice Cupressuses and *Retinosporas*. In the background are

with deciduous trees, including the deciduous Cypress, *Taxodium* *distichum*, a fine Tulip Tree unfortunately nearly destroyed by the violent September gales, and a beautiful specimen of the American Liquidamber or Sweet Gum Tree, of which the autumnal tints are so glowing and so rich. In the centre of this lawn is an orangery, the south wall of which is covered with Myrtles, Magnolias, and *Maréchal* *Niel* and the “Old Yellow Tea” Roses. The Rose last mentioned is most valuable, for it grows freely and blooms profusely and continuously. It is one of the earliest, latest, and most admired Roses at Holme Lacy. On the left is the topiary work, not represented by fantastic shapes, but huge masses of closely shaven Yew, 12 to 15 feet high, half as much in diameter, and two hundred years old, smooth yet not formal, but irregular in height and outline, with lancet window-like openings into the flower garden, and quadrangular-like recesses, bold and severe. At the end, or rather what appears to be the end, is apparently a huge bank of Yews growing across the walk; and rising from the Yews, towering in lofty altitude, is a group of Scotch Firs, remarkable by their height, colour, and beauty. Their red trunks are almost destitute of branches, and when illumined by the rays of the morning sun produce an effect which it is doubtful if a “doctor,” much more a patient, could adequately describe. I have seen, perhaps, thousands of acres of Scotch Firs—Firs in England and in Scotland, and a glimpse of the Black Forest of the Continent, but I have never seen any equal to the red-stemmed specimens at Holme Lacy. This bold terminating feature is, however, not impenetrable, for as we approach nearer we find a porch-like opening, and we pass between the trunks of the Firs to an irregular avenue of forest trees and an undergrowth of Laurels. Parallel with this bowery glade is a real avenue—formal and correct—of Elms, as straight in the trunks as the pillars of a vast cathedral nave, and with Nature’s graceful arches formed high above amidst a delicate tracery of leafy sprays. At the base of these trees is a flowery and not closely shaven lawn—flowery because studded with bulbs and other spring flowers, such as Violets and Primroses, which Lady Scudamore Stanhope delights to plant in every available position where they will become naturalised. It is pleasing to note that in a garden where high-class modern flower gardening is so well carried out, and where stately border perennials are assiduously cultivated, that the lowly simplicities of nature are not overlooked, but are turned to account and made to beautify, as no other flowers can do, the sides of woodland walks and shaded glades and groves.

Having followed the terrace walk and avenue into which it merges, we reach the west end of the ornamental grounds, and find another point of vantage, from which the view is obtained as represented in the accompanying engraving (fig. 2). The standpoint here is singularly favourable for inspecting the grounds, which are in a measure overlooked, for reaching entirely across the garden is an elevated plateau of smooth lawn about 20 feet wide and perhaps 100 yards long. This artificially-raised lawn is some 5 or 6 feet above the general ground level, and constitutes an enjoyable and commanding promenade. There is no record as to the “authorship” of this elevated plateau, nor of course the object of it. Possibly it may have been designed for the purpose it serves so well of enabling the beauties of the garden and the country beyond being inspected so conveniently and satisfactorily. On the extreme left of the view is shown the lofty Scotch Firs which have been referred to as terminating the west end of the south terrace walk. Next comes the flower garden, which is 160 yards in length by about 40 in breadth, surrounded by a gravel walk and bounded by dense Yew hedges. This garden has been formed by the present baronet. The lawn contains as many flower beds as can conveniently be formed, and in the summer would be almost overpowering by the blaze of beauty were it not for the sobering frame of Yew which surrounds the floral picture. The correct arrangement of the colours in this garden is a subject which receives the special attention of Sir Henry and Lady Scudamore Stanhope, who devote to it much thought and long deliberation. The result is that the massing system is displayed in the best manner of which it is capable; and as a compliment to the owners and artists the late Mr. J. R. Pearson named after them two of his best bedding Geraniums—namely, Sir Henry Scudamore Stanhope, which is a finer crimson than even General Outram, and Lady Scudamore Stanhope, which is one of the brightest and most effective of the orange-tinted varieties. These and others of the best Chilwell Geraniums, with older sorts of proved

excellence, are largely employed, together with beds of *Petunias*, *Ageratums*, *Heliotropes*, *Calceolarias*, and other plants of that nature, associated with *Lobelias*, *Iresines*, *Mesembryanthemums*, *Centaureas*, and *Cerastium Biebersteini* as edging plants. The plant last named is seldom seen now, but is one of the most effective of low-growing silvery-foliaged plants. The beauty of this flower garden is considerably enhanced by a series of small square beds, each about 2 feet in diameter, which are arranged about 4 or 5 yards apart near the margin of the lawn next the side walks. These squares were planted with a central plant of *Perilla nankinensis* in a groundwork of *Nierembergia gracilis*, and a centre of *Centaurea gymnocarpa* in a groundwork of blue *Lobelia* alternately. This arrangement was strikingly effective, and suggested how much can be done in a plain manner and with simple material when good taste is exercised. Round beds by the sides of the long straight walks and near those closely and squarely-clipped hedges of Yew would have been out of character, while the appropriate-

ness of the squares was so manifest as to command approbation at the first glance. These little marginal beds were happily conceived and admirably planted, and imparted a decided finish to a splendid flower garden—a garden which both by its extent, formation, and its close masses of well-arranged colour reminded me of the display in the renowned garden at Dirleton Castle (Archerfield), only at Archerfield the beds are on gravel, at Holme Lacy they are on grass.

From the modern to the ancient system of flower gardening is but a few steps. The herbaceous flower borders at Holme Lacy are shown in the centre of the engraving, and constitute one of the finest features of these attractive grounds. The borders by the sides of the Yew hedges are about 5 feet wide, and are longer than the modern flower garden; and the promenade, which is 9 feet wide, is of smooth and admirably-kept lawn. These are not newly made borders formed to display an old system of decoration which is now becoming popular and deservedly so, but they have been herbaceous borders from

Fig. 2.—HOLME LACY—VIEW IN THE GROUNDS.

time immemorial. Beautiful indeed must be these borders in the spring long before the modern garden "over the hedge" can display a single flower save the marginal line of Crocuses at the foot of the Yew fence; and the borders are attractive, too, after the Geraniums have succumbed to the autumn rains and frosts. But it is in the spring and early summer that they are the most admired. They contain early-flowering bulbs by thousands, and these associated with *Myosotides*, *Daisies*, *Aubrietias*, *Arabises*, and other dwarf spring flowers produce an effect that can only be afforded by such flowers when growing in semi-wild masses. Of taller-growing plants which prolong the display are fine clumps of the beautiful and stately white Lily, *Lilium candidum*, which appear to great advantage with the dense dark background of Yew. Colour is imparted by *Tritomas*, *Pentstemons*, *Gladioluses* and *Phloxes*, and grace by *Pampas* and *Ribbon Grasses* and *Fuchsias*. Numerous other border flowers assist in the general display during the summer; and in the autumn the *Asters* (*Michaelmas Daisies*) impart cheerfulness by their pleasing masses of varied colour. This "Green Walk" as it is called, with its well-filled flower borders bounded by Yew hedges, with the vista formed by an opening through the Yews of the Dutch or terraced garden above alluded to, onwards across the deer park and over the Wye, terminating with the Caplar Mill and an old Roman

encampment visible thereon, is one of the most beautiful features of Holme Lacy.

Near the termination of the herbaceous border on the right an opening through the Yew hedges conducts to the roseroy—a beautiful spot. On the lawn are beds of dwarf Roses and standards singly planted in the turf. Clematises on wire trellises are pillars of beauty, and *Arundo conspicua* again displays its silvery elegance. On the lawn, too, a "simplicity" is worthy of mention. It was simply a wire trellis 5 or 6 feet high with an umbrella-shaped head covered with the Canary Plant (*Tropæolum canariense*), the golden sprays of which depending like a fringe had an unique and striking effect. This beautiful lawn ornament can be easily formed in any sheltered garden. In addition to the flowers in this secluded enclosure are specimen Hollies and other shrubs relieved by a few weeping Birches. The surrounding hedges are about 4 feet high and wide, except that on the north side through which the entrances are, which is 12 to 15 feet high and 8 or 9 feet wide. Such is the roseroy: it comes on the visitor as a charming surprise, which cannot fail being enjoyed by all who inspect it during its summer beauty.

On the south of the "Green Walk" is the nursery for the raising of young trees and shrubs, and beyond this, next the park, is the "old pot orchard." The term "pot" signifies

that the fruit is grown for dessert and culinary purposes, and not for cider and perry. The cider orchard, the wonderful "travelling" Pear tree, and the "cordon wall," to which I intended alluding this week, are "crowded out," and notice of them must necessarily be deferred to a future issue.—J. WRIGHT.

HYMENANTHERA CRASSIFOLIA.

IN general appearance this low-growing hardy evergreen shrub is not unlike a *Cotoneaster*. It has the same sub-procumbent growth as *C. microphylla*, the same small closely-arranged leaves, the same profusion of berries; yet it is very distinct both botanically and ornamentally from the familiar evergreen

alluded to. *Hymenanthera crassifolia* is conspicuous by its pearly-white berries, which are freely produced during the autumn and winter months. They are of the same size as Mistletoe berries, but are more elongated and are chiefly borne at the base of the branchlets. This shrub is suitable for planting near the sides of walks, or preferably on mounds, rockwork, or the sides of steep declivities, from whence it can be viewed from below, and its numerous and curious berries be seen to the best advantage; generally speaking, however, positions that are suitable for *Cotoneasters* are suitable also to this distinct white-berried shrub, which is a fine companion to the *Cotoneasters*. *Hymenanthera crassifolia* is a native of New Zealand. It is quite hardy, grows freely, and flowers and

Fig 3.—HYMENANTHERA CRASSIFOLIA.

fruits profusely in the Coombe Wood Nursery of Messrs. James Veitch & Sons. It is one of the most novel and chastely ornamental of low-growing evergreen shrubs.

ROSE DEVONIENSIS.—In the Rose election lists this Rose is stated to be raised by Mr. Curtis. A letter from Messrs. Lucombe, Pince, & Co. tells me that it was raised or introduced by Mr. Pince. Evidently the climbing variety is the most appreciated, being more robust and larger, but this is only a vigorous sport from the old variety.—JOSEPH HINTON, Warminster.

[The old *Devoniensis*, as may be seen from a letter from Mr. Conning on page 387, November 15th, 1877, was raised by George Foster, Esq., from whom it passed into the hands of Messrs. Lucombe, Pince, & Co.—EDS.]

NOTES AND GLEANINGS.

THE COUNCIL OF THE ROYAL HORTICULTURAL SOCIETY submit to Fellows and Members a statement, from which it

appears that the end of 1876 found the Fellows as a body dissatisfied with their privileges and divided into hostile sections, their resignations alarmingly numerous, and new candidates for the Fellowship few; the Council unable to satisfy the conflicting wishes of the contending parties, obliged to maintain South Kensington Gardens, and without funds in possession or prospect sufficient to carry on the Society with credit to the end of the year 1877. In this situation all parties saw the necessity for mutual concessions, and the Society ceased to be torn by internal strife. The privileges claimed by Fellows were granted to them and added to, and a new body of Annual Members created. Resignations ceased, and candidates for admission presented themselves in numbers which, though absolutely large, are still far short of those required to place the Society on a safe footing for the future. The Council desire to render the South Kensington Gardens attractive to London Fellows and Members, and with this object will provide a band and give promenades every Saturday while the attendance justifies the outlay. These promenades will commence on Saturday January 19th, will during the winter last from 3 to 5 P.M., and be held in the conservatory, which will

be warmed, and when necessary lighted at dusk. Fellows' tickets and small book orders will admit to them; and to render them select the minimum charge to the public will be half a crown. Members will have personal admission. From wishes expressed at General Meetings and otherwise conveyed to them the Council believe that a summer fête, to be held in the evening, would yield gratification to many of the Fellows, and they will give the subject their consideration. Fellows' privileges will remain as settled this year. Lists of these and of the promenades, exhibitions, and shows for 1878 will be sent to each Fellow and Member in due course. Although the position of the Society has improved to an extent that could scarcely have been anticipated at the beginning of this year, the Council must remind Fellows and Members, especially those resident in London, that the aggregate amount of their annual subscriptions is still far short of the £10,000 which must be raised from that source during the next twelve months to prevent the forfeiture of the South Kensington Gardens. The money must come from the subscriptions of Fellows and other annual subscribers. If not so raised the Gardens will be forfeited, and perhaps built over; if so raised, they will be secured to the Society for fifteen years. The Council believe that if Fellows and Members exert themselves individually to induce their friends to join the Society, the amount required, which exceeds the average income from subscriptions in the years 1871 to 1874 inclusive by less than £2000, can easily be obtained. If the Gardens are to be preserved this effort must be made at once.

— WE have received the following extract from the translation of the General Regulations issued by the Ministry of Agriculture and Commerce, relating to the PARIS UNIVERSAL EXHIBITION OF 1878. In the ninth group (horticulture) Class 85—conservatories and horticultural apparatus—includes also gardeners', nurserymen's, and horticulturists' tools; apparatus for watering and keeping turf in order, &c; large conservatories and apparatus appertaining thereto; room and window conservatories; aquariums for aquatic plants; fountains and other means for ornamenting gardens. Class 86—flowers and ornamental plants—comprehends species of plants and examples of culture exhibiting the characteristic types of the gardens and dwellings of each country. Class 87—vegetables—species of plants and examples of culture exhibiting the characteristic types of the kitchen gardens of each country; and Class 88 fruit and fruit trees, species of plants and specimens of products exhibiting the characteristic types of the orchards of each country. Class 89—seeds and saplings of forest trees—refers to species of plants and specimens of products illustrating the processes followed in each country for planting forests; and Class 90—plants for conservatories—is intended to illustrate the mode of culture adopted in various countries with a view either to pleasure or to utility.

— MANCHESTER BOTANICAL SOCIETY.—The following are the dates of meetings arranged for 1878:—Annual Meeting, January 14th; Floral Meetings, Town Hall, March 19th and April 30th; Great National Exhibition, June 7th to 14th; National Rose Society's Show, July 6th; Cottagers' Show, August 3rd; Chrysanthemum Show, November 26th.

— MR. KIPPS states that there are many complaints of the young leaves of *HOLLIES* falling off extensively in the neighbourhood of Warrington, and asks if a similar occurrence has been observed in other places. He would be glad also to know the cause of the defoliation. The great crop of berries on many trees has doubtless impaired their vigour considerably. We noticed many Holly sprays in Covent Garden Market at Christmas nearly leafless.

— "A COUNTRY VICAR" writes—"Assuming that the POTATO DISEASE is caused by a fungus, I should like to ask whether anyone has tried to kill the fungus by applying a solution of carbolic acid to the tubers before planting?"

— FEW stove plants are more brilliant at this period of the year than well-grown *GESNERAS*, such as *G. cinnabarina* and *G. exoniensis*, and their foliage is as handsome as their flowers are bright. We have recently seen plants in 6-inch pots with large velvety foliage and glowing pyramidal spikes of flowers of the most dazzling colour. For the winter decoration of stoves and even warm conservatories, also for dinner-table embellishment, we cannot imagine any plants producing a richer effect than these. They are also of easy culture. A shelf in a well-heated stove, Cucumber-house, or Pine pit if suitable, will accommodate a goodly number of plants, which when in bloom keep fresh and healthy in a minimum tempera-

ture of 50°. All who desire bright flowers to succeed the *Poinsettias* should grow these handsome *Gesneras*. For flowering at this period of the year the tubers must be potted in July.

— WE are informed that H.R.H. the Prince of Wales has presented a GOLD WATCH to MR. C. EDMONDS, who is about to retire from the superintendence of the gardens at Chiswick House; and that the Duke of Devonshire provides a pension for Mr. Edmonds in recognition of his long and able services. Mr. May, who has for some time past been foreman at Chiswick, is promoted to be head gardener.

— A CORRESPONDENT, "T. L.," informs us that Miles' hybrid spiral *MIGNONETTE* is as valuable for winter as for summer decoration. He has, he states, plants now flowering profusely, and the spikes are both very large and highly fragrant. A great impetus should be given to the culture of this fine variety by the liberal prizes offered by Messrs. Brooks & Gallop—viz., £10, £7, and £5 for twelve plants in 6-inch pots, to be competed for at the Royal Horticultural Society's Great Summer Show, which opens on May 28th at South Kensington.

— WE understand that Captain Carter of Brighton, and T. C. Gravelly, Esq., of Cowfold, Horsham, have kindly consented to act as local Secretaries of the NATIONAL ROSE SOCIETY in their respective localities.

— A CORRESPONDENT writing to us from the State of Wisconsin, U.S.A., and who has resided for several years both in England and America, is of opinion that the danger of the COLORADO BEETLE becoming established in England is not nearly so great as is represented. He states that in the district where he resides that it is only during exceptionally bright and hot summers that the "bug" does serious damage; in ordinary seasons they "take no notice of it." The English climate he considers to be too cool and moist for the beetle to increase to anything like the extent it has done during the long tropical summers in America. He describes the "bug" as a tropical insect that will not "succeed" in a temperate climate. We hope he may be right, but at the same time shall consider it prudent to adopt every possible means to prevent the experiment being tried in our gardens.

— WE lately noticed in one of the houses at Messrs. Osborne's, Fulham Nursery, a very fine group of that valuable winter-flowering plant *LUCULIA GRATISSIMA* in small pots. The plants were only about 5 or 6 inches in height, perfectly clean, the foliage covering the pots, and the flowers very fragrant. In another house the lovely *Plumbago rosea* was producing grand spikes of flowers. For the stove as a pot plant nothing can be more graceful than this *Plumbago*. The flowers are also suitable for cutting, but they do not last long in water.

— MR. ROBERT FOULIS, who was gardener and bailiff at Fordel, Fifeshire, for more than fifty years, died on the 21st ult. "full of years and honours." He was in his eightieth year, and was the recipient of the Neill prize awarded by the Managers of the Royal Caledonian Society in 1876, and was subsequently presented, at a complimentary dinner given in Edinburgh, with a gold watch and a purse of sovereigns. Mr. Foulis was a man of considerable attainments, and was held in great esteem by all who knew him.

— WE regret to hear that PILFERING FROM SUBURBAN GARDENS is unpleasantly common. A valuable collection of hardy Ferns recently disappeared from a rockery on the west of the metropolis, and we are informed that several Roses have been stolen from Mr. Hales' collection at Tottenham. The disappearance of plants from window-sills is also prevalent. It is possible that a gang of nocturnal thieves have adopted this mode of "dealing in plants," stealing them from one district and selling them in another. It is a pity that such rogues cannot be caught and convicted.

— SINCE the weather has continued mild during such a long period, it will be well that the POTATO STORES be examined. The tubers for planting will, if stored in any considerable thickness as they are often obliged to be, have now commenced growing, and if not exposed to light and air the early growths will be wasted. It is of great importance that the seed tubers be well prepared so that their growth is slow and sturdy, which is the first condition for securing early and good crops. If kidney Potatoes are placed on their ends in trays or shallow boxes it is surprising how many can be accommodated in a small space; and if these are placed in a light

place and in gentle warmth they will be in a much better condition at planting time, and eventually more profitable, than if left to produce weak growths in the stores or in a dark place. We direct attention to this simple but important matter before serious evil is done by thick or prolonged storing of the seed tubers. They should be examined at once and be placed in a position where their growth can be green and slow, not white and rapid.

— It is, perhaps, not generally known that the distinct and bright *BEGONIA FRÖBELII* not only comes quite true from seed, but that attractive flowering plants are produced the same season that the seed is sown. The seed should be sown in heat as early as possible, and with careful and good culture floriferous plants will be produced during the summer and autumn. The colour of the flowers is very bright, and the habit of the plant is distinct from the ordinary type of tuberous Begonias, inasmuch as the leaves and flower stems of *B. Fröbelli* issue direct from the root the same as *Gloxinias*. Well-grown plants are very attractive for conservatory decoration, and are also suitable for flower-garden purposes.

— We have received the "Garden Oracle" by Mr. Shirley Hibberd, and are pleased to observe that it maintains the reputation it has enjoyed for many years in furnishing useful information on a variety of subjects.

— THE practice of planting MEMORIAL TREES has long been a favourite occupation with the members of the Royal Family, and on occasion of Her Majesty's recent visit to the Premier at Hughenden, trees to commemorate this special mark of the Sovereign's favour were planted on the lawn by the Queen and the Princess Beatrice. The trees selected for the purpose were *Picea nobilis* and *P. Nordmanniana*.

— EVERYTHING, says an American lady in the *New York Herald*, which tends to make us better and happier, to purify our lives and refine our tastes, should find a large room in our sympathies. I take the ground that it is the duty of every household to raise at least a few flowers. We need them for our children's sake, we need them for our friends, we need them to beautify our homes and make them attractive, we need them for festive occasions—and oh! if the destroyer enters our dwelling and lays some loved one low, how their frail but beautiful forms send our thoughts heavenward and almost mitigate our grief!

— We are informed that the RICHMOND HORTICULTURAL SOCIETY is in a flourishing state. Last year's income exceeded £500; upwards of £230 was expended in prizes, and a balance of £50 is in the Treasurer's hands. During the ensuing year medals are to be had in lieu of money if desired by the successful exhibitors. The affairs of the Society have been conducted both with spirit and prudence by Mr. Chancellor, the Secretary, and an efficient Committee, who have merited the success they have achieved. No suburban shows have surpassed those held at Richmond during the past few years, and we hope for similar successful gatherings in the future.

— "A KITCHEN GARDENER" writes, "We have a very fair variety of *CHRYSANTHEMUMS* here, and we have had an excellent show of flowers all through November and December. In our house we had a front row over 300 feet in length, which was greatly admired, but now when the new year is only three days off we are left with only one variety in flower, a yellow, named Japan Dragon. Would any of your numerous readers kindly name a few late-flowering sorts which would come into flower at the beginning of January and continue in bloom throughout this month? Varieties flowering now would be much more valuable than the very early kinds."

— THE by no means common herbaceous plant *CHELONE OBLIQUA* has been particularly floriferous this season. It has been in bloom from the middle of July to the middle of October; and notwithstanding the almost ceaseless rain that has descended on it during the greater part of that time, it has maintained a constant display of its beautiful purplish-red flowers. It is a choice herbaceous plant, worthy of a place in the gardens of the most fastidiously exacting persons as to what shall and what shall not be admitted to their collections of that class of flowers. It is from first to last a tidy-looking plant, and that without causing any trouble in staking or otherwise, its stiff woody stems requiring no support whatever.—(*Gardener.*)

— "A SURREY AMATEUR" calls our attention to the "capriciousness" of his *LAURUSTINUSES*. Last year, he says, when he had no Holly berries and required *Laurustinus* flowers for Christmas decoration his shrubs were only "in bud," and

the flowers did not expand until February; this year, now, Holly berries are plentiful and *Laurustinus* flowers are less required, the shrubs are covered with flowers. As the autumn of 1876 was not colder than that of 1877 our correspondent cannot account for the striking difference in the period of his shrubs flowering. Neither can we.

— IN many parts of the country PRIMROSES in the hedges are in full blossom. Owing to the wet season they became well established in the soil; then came a spell of dry weather, which ripened the growth, and this, followed by mild and open weather and genial rain, has induced their early floriferousness. Violets are also flowering freely in the lanes of Sussex.

— MR. ERNEST BERGMAN asks if readers of the Journal would state the age and size of any large *ARAUCARIAS* in the gardens of this country, and where such trees are growing. We should be glad to receive information on this subject.

WORK FOR THE WEEK.

KITCHEN GARDEN.

ANY digging and trenching yet remaining to be done should be proceeded with as expeditiously as the weather permits. Much of this kind of work is in arrear owing to the unfavourable state of the ground for wheeling manure. It is questionable whether it would not in wet seasons be advisable to dig or trench the ground before it is manured, placing the manure on afterwards during frost. The dung would lose little or nothing by exposure, and the extra turning-over of the soil to get it under could not act otherwise than beneficially. Kitchen gardens long under cropping would be improved by the addition of fresh loam, especially light and shallow soils; very light soils are permanently improved by a good marling, whilst heavy soils are improved by ashes charred, refuse, or burned clay. Take advantage of every opportunity to secure material for compost. Road scraping, parings of turf (no matter how rough), ditch cleanings—anything in fact that when reduced will make a heap of soil, turning it over not more distantly than every three months, and if fresh lime be added at the rate of one ton to six of compost decomposition of the vegetable or animal substances will be more speedily effected.

If a sowing of Peas was not made in autumn, or if those sown then are not doing well, make a sowing now on strips of turf cut 2½ inches thick and 4 inches wide. Cut a hollow in the soil side of the turf half its depth, sowing the seed in the hollow, and cover with an inch of light soil. Place on the floor of a late Peach house, orchard house, or cold frame, and when the Peas are 4 inches high plant the turves containing them at the foot of a south wall. Let the upper sides of the turves be an inch deeper than the surface of the ground. Dwarf kinds, as Little Gem, Blue Peter, or Unique, may be sown one foot from the wall, and will come in very early; William I. and Shah to be sown on warm borders with the rows 8 feet apart. Horseshoe drain tiles, shallow narrow boxes, or pots may be employed for sowing-in in lieu of turf.

Where Cucumbers and Melons are grown by the aid solely of fermenting materials preparation should be made for forming the beds by throwing the material into a heap, watering if dry, and turning it over when in good heat, casting the outside to the inside, the object being to induce a high condition of fermentation and to get rid of the rank steam. Beds to be made of sweetened dung and leaves about 8½ feet high preparatory to planting with Potatoes, also for sowing Carrot, Cauliflower, Lettuce, and Radish seed. When the heat has risen place the frames on the bed and cover it with 4 inches of rich light soil for the seeds, and 6 inches for the Potatoes. The Carrot (French Forcing) and Radish (French Breakfast and Wood's Frame) may be sown together, the Radish being drawn before the Carrots, and the Lettuce (Early Paris Market) sown in drills 6 inches asunder, and the Cauliflower (Dwarf Erfurt Mammoth and Early London) between the rows, pricking off the latter when having a rough leaf, and thinning the Lettuce to 6 inches distance, planting the thinnings on a warm border. The lights must be drawn down in all mild weather; any attempt at keeping close until the second leaves have formed will destroy the crop; but when the second leaves are formed the lights may be kept closer, admitting air however freely, and keeping moist by watering with weak liquid manure with the chill taken off. Protection must be given in severe weather; it need not be more than to secure safety from frost. The Potatoes—Veitch's Ashleaf is first-rate, also the old Ashleaf and Myatt's Prolific—to be planted with sprouts an inch long (they having been placed in boxes in a warm place a fortnight previously) 4 inches deep, making sure that the temperature of the soil at that depth is not over 75°. No air need be given until growth appears above the soil, when air must be admitted freely, seeking to obtain as high a day temperature (55° to 65°) as can be had with moderate air-giving without drawing the plants, making safe at night by ample protective material over the lights in severe weather.

Continue to put in successional batches of Seakale and Rhubarb, they forcing readily in a Mushroom house or other dark place with a temperature of 55° to 60°; also Asparagus, which is best forced on beds of fermenting material. Admit air freely in mild weather to Lettuces in frames and Cauliflowers under handlights. If slugs are troublesome sprinkle with quicklime after removing any decayed leaves, and stirring the soil about the plants. Look over Broccoli; any of Snow's or Veitch's having heads 4 inches across to be taken up and planted in frames where they can be protected from frost. Pot a few roots of Tarragon, Mint, and Sorrel, placing in a vinery or other house at work. Parsley may also be potted and if placed in a Peach house started about this time will be found very useful in severe weather. Small saladings is much in demand at this time of year. Continue sowing at intervals of four or six days, or more distantly, according to the demand; it, though brought forward quickly in a temperature of 60° to 75°, is best removed to one of about 50° when fit for use. Endive will now form the principal saladings. Keep it safe from frost and wet; tie up or cover, so as to have it thoroughly blanched, which takes from three weeks to a month in cold pits, whilst in a Mushroom house it blanches readily in ten days to a fortnight. Protect Celery in severe weather with litter, removing the covering when mildness ensues.

FLOWER GARDEN AND PLEASURE GROUND.

Beds of bulbs, and such plants as Fancies, &c., planted in autumn will be the better if mulched; it contributes to the good appearance of the beds, and prevents the soil being acted on by frost to the upheaving of the plants. Cocoa refuse is a capital material, also light compost, as decayed leaves. Herbaceous borders should have a dressing of compost at least once a year, taking advantage of the first frosty weather to get it on, and of the first mild day to fork it in. It is now that the beauty of evergreens is apparent; they are only enjoyable when the lawn is kept free from wormcasts, which are best removed by a wood roller followed by an iron one, making the turf look firm and fresh. Walks too must be swept and well rolled. Neatness everywhere prevailing renders a pleasure ground as interesting, if there be a goodly assortment of evergreens, and as enjoyable at this season as any other. Push forward all alterations, especially groundwork, in order to give time for settling and being able to regulate any inequalities before turfing. Any ground sufficiently advanced for the turf may have it laid whenever the weather is mild. Though we do not advise the planting of evergreens in midwinter, exception may be had to work of this kind when the shrubs are not crowded, and it is only a question of moving them with good balls from one position to another in the same grounds. Deciduous trees move quite as well in mild weather at midwinter as any other time, provided the roots are not long exposed to the atmosphere and the trees are secured against winds after planting. Choice Conifers we consider are best planted in spring, just before commencing growth, or in early autumn; but the hardier kinds will move at almost any time from September to April, the chief considerations being good roots and thinly grown specimens.

FRUIT HOUSES.

The trees in the earliest Peach house if started at the beginning of the month will now be in flower. The temperature from fire heat by day may be 50° in dull weather, rising to 65° with sun, air being freely admitted and a little left on at night, anything like a close stagnant atmosphere being fatal to the blossom; at night the temperature may fall to 40°. A moderate moisture in the atmosphere will suffice; in bright weather the floor may be sprinkled in the morning, the soil being kept in a thoroughly moist condition. Impregnate the blossom either by shaking the trees lightly in the early part of the day, or go over each blossom with a camel-hair brush and apply some of the pollen to the stigma. The small-flowered kinds set much better than the large-flowered, some of the latter being deficient of pollen. Take from those having abundance and apply where there is a deficiency. A hive of bees placed in the house will do the work much better than any shaking or brush, the bees evidently enjoying the warmth and the work. Later houses to have the trees cleaned, pruned, and tied, and the borders dressed, giving a good watering. For the first fortnight no fire heat need be applied unless frosty, when, it being necessary to have the fruit ripe by a given time, the temperature should be kept at 50° by day and 40° at night, allowing it to rise to 65° by day from sun heat, accompanied by plenty of ventilation, sprinkling the trees morning and afternoon until the blossom commences to open, when the sprinkling of the floor in place of the trees will be sufficient. If the roots are partly outside that part of the border should be covered with leaves and litter 12 to 15 inches deep in a state of fermentation. It may not warm the border much, yet the rains, which pass through the warm litter, will reach the roots at a higher temperature than were there no such intervening material; besides, such coverings attract the roots to the surface. For the same reason Vine borders should be covered with not less than 18-inch thickness of hot dung and leaves, replenished from time to time as occasion may arise; and for raising a genial warmth and moisture inside the house a bed of fermenting material is highly to be recommended, as lessening the necessity for fire heat and

securing in most instances a good break. A temperature of 50° minimum and 65° maximum from fire heat is to be advised until the eyes break, with a rise from sun heat and air to 75°, after which the minimum should be raised to 55°, having it 60° by the time the shoots are an inch long, and 65°-60° night when in leaf, and 70°-75° by day. Nothing is so injurious as a high and dry atmosphere in the early stages of growth. The Vines to be sprinkled morning and evening, and the floor, &c., damped at noon, and the evaporation troughs kept full of water always.

PLANT HOUSES.

The conservatory will be gay with Camellias; those swelling the buds may be assisted by weak liquid manure, keeping the soil thoroughly moist. Plants in flower or approaching thereto require more plentiful supplies of water than those at rest, but over-watering hardwooded plants is as baneful when in flower as at any other season. Conservatories being kept much drier than ordinary plant houses, we advise more copious supplies of water to be given the plants to lessen in some degree the effects of the drier atmosphere. A batch of Hyacinths, Narcissus, &c., should be taken from their cold quarters and be introduced to a house with a temperature of 45° to 50°, placing them on shelves near the glass; and if a few pots of Violets are at command introduce them at the same time; their perfume is always acceptable. We have De Parme Violet in 4½-inch pots—the sweetest, most floriferous, and continuous-flowering of all the Violets, this being a Neapolitan; with double white and red Primulas, Persian Cyclamens, Roman Hyacinths, Double Roman and Paper White Narcissus, are all sweet beautiful and dwarf, which anyone may have with a greenhouse for making their homes cheerful at the opening of the new year. Few plants force more readily than Rhododendrons and the hardy Azaleas, the latter combining fragrance with beauty. Of Rhododendrons early-flowering kinds should be chosen. Early Gem is very useful, and other good varieties were named last week by Mr. Moorman. Of Azaleas the A. mollis vars. are admirable, as are the many Ghent varieties. Some of the dwarf Rhododendrons are very sweet, notably R. fragrans and Govenianum. The Guelder Rose, with its "balls of snow," is fine for forcing—finer still the Japan species Viburnum plicatum with its globular heads of white flowers; Prunus sinensis flore-pleno, also with double white flowers; Deutzia gracilis, known to everyone, and D. crenata candidissima plena have white flowers, which should have a place among forced shrubs. Lilacs—Persian White and the old White Lilac—need no blanching to have the flowers white, but Charles X. has larger flowers—purple if exposed to light, but may be had white by growing in the dark. Few plants are sweeter than the trailing Daphne Cneorum major, its pink flowers along with those of Kalmia latifolia and K. myrtifolia being very beautiful. In herbaceous plants are Spirea japonica and S. palmata, both of which require very plentiful supplies of water when in growth, and to be kept from tobacco smoke, which injures the foliage. Dielytra spectabilis is a fine decorative plant in early spring, and forces splendidly; Lily of the Valley, with flowering crowns an inch apart in pots or pans along with a goodly number of Roses Tea and Perpetual, also Moss for buds, all prepared for the purpose, the gardener with conveniences for growing them may look complacently upon the coming season. They will do in a greenhouse, Peach house, or a vinery. Roses require to be brought on gradually, the Teas requiring very little pruning, merely cutting out any old exhausted wood; the Perpetuals cut back to two or three eyes, according to the strength of the shoots.

TRADE CATALOGUES RECEIVED.

James Veitch & Sons, Royal Exotic Nursery, Chelsea.—*Illustrated Catalogue of Vegetable, Flower, and Farm Seeds, Horticultural Implements, &c.*

B. S. Williams, Victoria and Paradise Nurseries, Holloway, London.—*Illustrated Catalogue of Flower, Vegetable, and Agricultural Seeds, Implements, &c.; also General Plant Catalogue.*

Daniel Brothers, Norwich.—*Illustrated Guide for Amateur Gardeners and General List of Garden and Farm Seeds.*

Francis & Arthur Dickson & Sons, 106, Eastgate Street, Chester.—*Illustrated Catalogue of Vegetable, Flower, and Farm Seeds.*

John Matthews, Royal Pottery, Weston-super-Mare.—*Illustrated Catalogue of Flower Pots, Vases, &c.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (Rector).—The best book on the flower garden is the "Handy Book of the Flower Garden" by David Thomson, published by Blackwood. Two little volumes published at our office—"The Flower Garden Manual" and "Florists' Flowers," also contain much information such as you require.

GARDEN PATHS (Mrs. Chapman).—There is no book specially devoted to the formation of garden walks and paths, but you will find ample information on the subject in any good work on gardening, such as the "Cottage Gardener's Dictionary."

GRAFTING ROSES (A. B. C.).—April is a favourable month for the operation. The kind of stock depends upon the form of tree you wish. Manetti for dwarfs, the Dog Rose for standards.

CHANGE OF MANURE (S. G.).—As you require the stable manure for another purpose than your gardening, and your soil is infested by grubs, apply guano and common salt.

GARDEN DIARY (Gardener).—Select one from Lettis' Diaries. The quarto size would suit you, as there are spaces for notes on each day.

MYROBELLA OR CHERRY PLUM (Hather).—This is the *Prunus Myrobalana*, a native of North America, and grown in shrubberies and gardens as the Cherry Plum. Its rate of growth is that of the common Plum, and is from 15 to 30 feet high, being most dwarf in poor soil.

YELLOW-BERRIED HOLLY (Constant Reader).—It is very commonly cultivated, and is only a variety of the common Holly. Botanists distinguish it as *Ilex Aquifolium flavum*.

PRIMULA LEAVES DECAYING (A Subscriber).—Being very luxuriant and placed near the glass they have been injured by the low night temperature.

CORRESPONDENTS (J. W. T.).—We have them in all districts of the British Islands.

CUCUMBER ROOTS DISEASED (H. B.).—The excrescences are caused by the puncture of a beetle, and in almost each excrescence a maggot will be hatched.

APPLES (R. W.).—Lord Lennox and Bramley's Seedling are in use from October onwards through the winter months.

MAGNOLIA FOR SOUTH WALL (J. H. E.).—We presume you require an evergreen variety. *Magnolia grandiflora* *Gallisoniensis* produces its large white fragrant flowers freely on young plants; *M. grandiflora exoniensis* being also free-flowering, but not upon young plants. Either will suit you. For the "trelliswork screen through which the north wind blows" no evergreen climber except Ivy would succeed, but it is probable that *Cotoneaster microphylla* or *Berberis stenophylla* would cover the screen. *Jasminum nudiflorum* is very cheerful in winter by its bright yellow flowers, but the plant is deciduous. The Apple is Dr. Harvey. Any nurseryman can supply you.

HEATING CUCUMBER AND MELON HOUSE WITH FLUE (G. H.).—As you do not require fruit before July you may dispense with top heat, only we presume you will require fruit late in the season, in which case top heat is necessary. Eight-inch drain pipes will answer if they are not subjected to too great heat, which causes them to crack. The furnace need not be more than 2 feet long, 13 inches wide, and as much in height. It must be formed of fire bricks, and the top arched. An asphalt of a foot depth will be necessary. The flue should rise from the furnace its full depth—*i.e.*, the bottom of the flue should be level with the top of the furnace and should rise gradually, or may be taken level to the chimney. For a distance of 8 feet from the furnace the flue should be constructed of firebricks; indeed, we should use bricks entirely for the flue with firetile covers 2½ to 3 inches thick. Three bricks on edge will suffice for height, and 9 inches width inside, the covers 15 inches wide. Take the flue all around the house midway of the bed, which we presume you will form on each side of the house, having the pathway in the centre; the side walls of the beds next the path we should have built pigeon-hole fashion, so that the heat could be diffused in the house, the bed to be filled with rough rubble on both sides the flue and raised 6 inches above it, the top of the rubble being covered with turves. Every 3 feet along the bed we should introduce 3-inch drain pipes reaching into the rubble, having one end in the rubble and the other above the surface of the soil forming the bed; by placing a slate over each pipe, the amount of top heat may then be regulated. The depth of soil should be 10 to 12 inches. If you use pipes cement the joints, leaving places that can be opened for cleaning the flue.

ROSES FOR AN EXPOSED SITUATION (Wm. Strong).—The heavy loam being well drained would be the most suitable for the Hybrid Perpetuals upon the Manetti stock, of which varieties that succeed with us are Alfred Colomb, Annie Laxton, Baronne de Rothschild, Baronne Louise Uxkuil, Bessie Johnson, Boule de Neige, Capitaine Christy, Charles Lefebvre, Claude Levet, Comte Raimbault, Comtesse de Chabrilant, Comtesse d'Oxford, Diann, Duc de Rohan, Duke of Edinburgh, Dupuy-Jamain, Edouard Moren, Etienne Levet, Fisher Holmes, François Courtin, François Michelin, General Von Moltke, John Hopper, La France, Louis Van Houtte, Lyonnais, Madame Lacharme, Madame Victor Verdier, Maréchal Vaillant, Marquise de Castellane, Miller Hayes, Prince Camille de Rohan, Princess Mary of Cambridge, Sénateur Valase, Thomas Mills, Xavier Olibo, Comtesse de Serey, La Souveraine, Miss Hassard, Princess Antoinette Strozio, Sir Garnet Wolseley, Duchesse de Vallombrosa, Oxonian, Antoine Ducher, Arthur Oger, Hippolyte Jamain, Comtesse d'Oxford, Madame Clemence Joigneux, Jean Dalmais, La Ville de St. Denis, and Gloire de Dijon (Tea-scented). Dwarfs only are suitable for exposed situations.

WOODLICE IN PEACH WALL (J. Q. F.).—We presume the mortar is much wasted forming crevices between the courses of bricks. The best process in that case would be to have the wall pointed, picking out the loose mortar and employing cement with a half part sand. Cement alone would cause too hard a substance for nailing. No wash that we know would reach the woodlice, as they will be secreted in the crevices of the wall.

PLANTING ROSES (Sussex).—We presume they are dwarfs. Plant them 2½ to 3 feet apart every way in quincunx order, the junction of stock and scion being buried 2 to 3 inches beneath the surface, mulching after planting, deferring pruning until March.

DRYING LILY OF THE NILE IN WINTER (Idem).—This is the growing season of this *Richardia*. They should be kept well supplied with water and have liquid manure at every alternate watering. If the plants are in a cool house they are better kept rather dry at the roots, yet having sufficient water to maintain the foliage fresh. If wanted to flower in winter afford a temperature of 55°-50° by night, and 60°-65° by day.

RENEWING VINE BORDER (J. B. Boyd).—We should remove the surface soil down to the roots and cover them with 6 inches of fresh soil, or if the roots are near the surface merely loosen it and apply 2 to 3 inches thickness

of fresh soil. The compost employed should consist of turfy loam light rather than heavy, with a sprinkling of half-inch bones, a bushel to about a cartload of compost, and twice that quantity of charcoal; and if the border were covered with fermenting materials 18 inches thick it would be a means of attracting the roots upwards and encouraging the speedy possession of the fresh compost. The road scrapings mixed with gas lime would not only be an unsuitable but a dangerous application.

LIFTING GLADIOLUS (Idem).—The roots of "fine kinds" should be lifted and kept cool and dry, but safe from frost, until March or the usual planting time.

STOVE PLANTS (Economy).—If you consult our little volume, "Indoor Gardening for the Many," you will be able to select for yourself.

FASCINATION (G. Duffield).—No one has accounted for such malformation. It occurs in various soils, seasons, and species.

SULTANA RAISINS (W. K.).—They are the dried berries of the White Corinth Grape Vine. It is described as follows in Dr. Hogg's "Fruit Manual"—"Bunches small, shouldered, and loose. Berries very small. Skin yellowish white, changing to amber, covered with white bloom. Flesh very juicy, sub-acid, and with a refreshing flavour. The seeds are entirely wanting. Of no value."

NAMES OF FRUITS (Knutford).—Your Apple is Trumpington. (H. L. E.)—Huyshe's Prince Albert.

NAMES OF PLANTS (Notice).—1, *Juniperus excelsa*; 2, *Thuja borealis*. (T. Granger).—1, *Sparmannia africana*; 2, *Eupatorium odoratissimum*; 4, *Echeveria coccinea*; 5, *Saxifraga sarmentosa*; 6, *Pilea allitricoides*; 8, *Davallia Mooreana*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

So immediately are many of our readers interested in and identified with agricultural as well as horticultural pursuits that we have decided to add a new feature to the columns of this Journal. That the addition will be generally acceptable we have sufficient assurance from the fact that it is the pressure imposed on us by the expressed requirements of many of our readers which has led us to widen the scope of our pages.

The alliance of Agriculture and Horticulture is so intimate and so natural that in thousands of instances the twin sisters march hand in hand. We rejoice in having the best evidence that the pleasures of the garden are increasingly popular; but we also know that they are with many divided pleasures—the home farm of the nobleman and country gentleman, and the glebe of the clergyman, sharing, as they naturally must share, the attention of those to whose residences they are such important accessories; in fact the two pursuits of farming and gardening are linked together and interbound.

The leading object that has ever been kept in view in the conduct of this Journal has been to constitute it a reflex of country life—an instructor in the wholesome and salutary pursuits in which so many are engaged—a medium of intercommunion between those of kindred sympathies. But it cannot be a complete reflex so long as one link remains unattached. Where the garden is there must bees be, and here they have been mirrored faithfully and truthfully for a quarter of a century; with the home there is poultry, and poultry have been continuously recognised in these pages; with poultry are runs, more or less extensive, of arable or pasture land. All, except the latter, which constitutes the home farm of 5 to 100 acres or more, and is so wide in its import, and has such a direct bearing on subsidiary industries, are represented in these columns, and we now add the missing link—THE HOME FARM.

In taking this step we propose to act within and not to exceed the bounds of our most special domain. We do not propose to enter into matters in which we are not ourselves actually, pleasurably, and profitably engaged. Agriculture as an exclusive pursuit has its exponents and a press conducted with singular ability, and which disseminates information of which the large professional farmers of the country avail themselves; but there is another class—a numerically great and important class, thousands of whom are our constituents, whose agricultural operations are not sufficiently

extensive to warrant them in availing themselves of the means provided for their co-workers.

Many gardeners, we also know, have a real interest—indeed a direct share—in the management of land and of stock, and those who are not intimately connected with this branch of husbandry have yet a natural attachment to it, so that they are not only willing but anxious to become more intimately acquainted with a calling so closely allied to their own; indeed, it is to their advantage to render themselves acquainted with practical agriculture in its various phases, because the acquisition of such knowledge is so greatly calculated to be of very substantial benefit to them. Young men who are looking forward to secure engagements in the families of the affluent of this and other countries cannot fail to appreciate the importance of becoming acquainted with the cultivation of land and duties connected with it situated beyond the confines of garden walls. We could adduce many instances of the great advantage possessed by those gardeners who have acquired a knowledge of farming operations, and of others of the necessity of obtaining such knowledge. We could point to the advancement of gardeners to bailiffs, and bailiffs to stewards, because those so advanced have been sufficiently acquainted with the rudiments of agriculture, which has enabled them to attain to positions of trust and comparative independence. Twice within a few days we have been commissioned to fill vacancies where the possession of some farm in conjunction with garden knowledge was indispensable; and having the welfare of gardeners so earnestly at heart we would strenuously urge on young men the importance of giving a share of attention to agricultural pursuits, knowing as we do from long experience and many examples that in proportion to the acquisition of that knowledge so are their chances of ultimate advancement proportionally increased.

To owners, holders, and managers of land on a comparatively small scale—those, indeed, identified with home farms—the subject of land cultivation in its various phases of tillage, manuring, grain and root culture, pasture and dairy management, and the breeding and feeding of stock, is necessarily a subject of primary importance.

In bringing this section of home pursuits within the scope of this Journal it is not at the sacrifice of those other branches of home industries and pleasures which have so long been familiar to our readers, and which have been welcomed in such a remarkable manner. Gardening in the same practical manner as heretofore will continue to be treated by old and valued friends and assistants, who have proved their competency by their success, aided by new writers of special proficiency in their several departments. Bees follow the flowers as usual, Poultry continue also, and the other allied features of home—Pigeons and Cage-birds; but Poultry is no longer isolated from the land. Thus the round of outdoor home exercises is rendered complete by including the Home Farm as a prominent and integral part of these pages.

The allied industries in connection with agriculture will be included as necessarily proper subjects for discussion. The great improvements in the mechanics of the farm and household exert a considerable influence in successful and profitable management, and will receive attention by way of determining their merits and applicability. The important section of manures, which now constitute a trade of great magnitude, will also be embraced as a subject demanding particular attention, being fraught as it is with danger or benefit, profit or loss. The not less important subject of seeds for the farm will also be adverted to when it can be done beneficially. The selection of pure and good seed and the best varieties are obviously of the

utmost consequence in successful farming, and the trade now established in agricultural seeds is one of the most important industries of the country.

In treating as occasion may require on the allied industries of agriculture we hope not only to be able to impart information but to provide a means for the expansion of trade in farming and home appliances, which is desirable because so directly and widely beneficial. Our facilities for doing this are exceptionally favourable from the connection which it is our pleasure to have formed and retained for so long a period with the homes of the nobility, clergy, gentry, and professional men of Great Britain and Ireland, together with an important business relationship with the continent of Europe and America.

INTRODUCTORY.

IN COMMENCING a series of agricultural articles we propose to refer to subjects connected with home-farming both in the management of land and live stock, and to introduce observations and remarks at the time of year when they may be considered most appropriate. We will, however, before entering upon questions relating to the future, take a retrospective view of the past year. We find the past season upon the whole has been unfavourable to agricultural pursuits; the crops of roots for cattle and sheep-feeding have been a fair average produce, excepting potatoes, which are a failure; the crops of hay both of uplands and meadows have been abundant, although in the northern and mid-land counties the harvest has not been good, and much hay has been damaged; grass-feeding for cattle and sheep has been plentiful and nutritious; the crops of both grain and pulse are much beneath the average, and in many of the northern counties the weather has seriously injured and depreciated the corn samples. In the southern and eastern counties, however, the harvest has not been amiss. The occupiers of land, rather than complain, and knowing that they can neither control the seasons or prices of produce, ought not to set their minds so much upon corn crops for profit, but consider that ordinary farming is seldom profitable, and therefore study to adopt some special production which may turn to better account. As usual, during the past month the exhibitions of cattle, roots, and grain have been held in almost every agricultural district in the kingdom, and have greatly increased in numbers and importance during the last twelve or fifteen years. When we consider that the splendid animals, the beautiful specimens of roots and grain exhibited, are produced by the intelligence, experience, and capital of the occupiers of the land, they ought to be considered as a valuable lesson to all engaged in the management of land, especially by those who have recently entered, or being about to enter, upon farming operations. Young men and beginners in the present day have at the different agricultural exhibitions offered to their notice, free of cost, the results of, in many instances, a lifetime of study and industry in the production both of live stock and vegetable products. The lesson taught, however, refers more to the comparisons of the different kinds and sorts of live stock and the weight and quality to which they will attain than to any practical method of feeding, &c. In the same way referring to the enormous size of the roots of mangel, swedes, turnips, cabbage, &c., beyond the comparison of sorts and quality there is but little to guide the novice in agriculture. We find, however, in some local clubs, where prizes are given for acreage weight, that the judges give not only the weight per acre but the manure used, the time of sowing, the number of roots per pole, and other minute matters, which certainly form a capital guide to the uninitiated and teach a lesson not so quickly and easily obtained in any other way. The number of farmers in the United Kingdom it is said amount to 400,000, and it is further said that 20,000 fresh men enter the lists annually. To nearly all the latter the various objects at the exhibitions are comparatively new, whether of live stock, roots, grain, or agricultural implements, and are appreciated accordingly.

We will now refer to the meetings of the farmers' clubs held lately in different counties, and we find that most important subjects relating to agriculture have been introduced, generally by men of long standing and great practical knowledge. Yet we find that after the reading of a valuable paper, showing great ability and intelligence, a discussion is opened by the members present, many of whom possess equal experience with the introducer of the subject; nearly all are found to differ upon some points, showing the extreme divergence of opinion even amongst those who possess great knowledge of the subject both practically and scientifically. This being the case, it may be asked at what time of a man's life can he look forward to for the completion of his attainments in agriculture? We reply, that to the most gifted and the most industrious, human life is not long enough on account of the circumstances by which he finds himself surrounded, which are ever varying. We therefore conclude that the practice and science of agriculture can never be entirely acquired, and that

although we may live long we ought ever to admit that we have much to learn.

MODE OF FEEDING STOCK.

THIS should be regulated by the age and previous condition of the animal. Half-starved store stock require very moderate and not rich feeding, for all their vessels have been adapted to poor thin circulating juices, and they are, consequently, of small capacity, unsuited for rich thick blood. Norfolk farmers, who go in for lots of cake and corn, will not wait for lean animals, but buy them well fleshed and in good condition, so that good feeding is no novelty to them. A friend of mine always bought in the autumn high-priced lambs, almost or quite fit for the butcher, and then he could at once feed them on the best of food, and thus fatten his land and his growing animals at one and the same time. Lean stock make starved and lean crops.

The condition of animal voidances is a pretty certain evidence of the results that are being produced. Turnips are either food or physic according to the quantity eaten. Excessive purgation is inconsistent with fat production. Instead of the usual three bushels, from 80 to 150 lbs. is all I allow, in addition to other and drier food. Succulent turnips alone cause immense losses in our breeding flocks.

An admixture of cut hay, cut straw, pulped roots, bean or oat-meal, cake, malt culms, and bran with a little crushed linseed or linseed soup is a good mixture. I generally add some condimental food which contains fenugreek. Hay of fine quality is in itself condimental, owing to some of its fine grasses. My cattle have always access to water and rock salt in lumps in their manger: rock salt is also in our horse mangers. In covered and enclosed yards there are no draughts. Nothing will give cattle pleuro sooner than a draught of cold air in a warm place. The temperature should be as uniform as possible.

Why are ladies' lap dogs almost always fat? Because they are well fed and kindly treated, warm and comfortable, and not unfrequently washed and combed. I know that where cows are groomed daily they thrive. We all know that if they can get access to a haulm wall, or a clipped wheat stack, they will groom themselves most heartily and vigorously. I once clipped some cattle on boards and then brushed them, and they fattened quickly. We are too sparing of a little expense in these matters. Many of those grand specimens of obesity at our great cattle shows are washed and groomed, and carefully and delicately fed. In fact, we see their attendants thus feeding them at the show. An ill-tempered, brutal stockman should have immediate notice to quit. A bullock's tongue is a sort of brush or currycomb, which if frequently used, but down the back and other parts he cannot reach, and therefore he feels truly grateful for a brush or scratch on these parts. Sometimes they oblige each other in this matter. —J. J. MEOHI (at the London Farmers' Club).

LANCASTER POULTRY SHOW.

THE second Lancaster Show was held on the 19th and 20th ult. It is already one of the most successful secondary shows; indeed, the poultry department ranks with the first shows, for nearly all the best Birmingham and Crystal Palace winners were there; and these, both from the adult and chicken classes being shown together, made the competition in some classes exceedingly close and the Judges' task very difficult. The show of Pigeons was quite unequal to that of poultry.

Ducks came first on the list. The first pen of Rouens contained a magnificent Duck, but a miserably paralysed drake. The winning Aylesburys were all good. The winners in the Variety class were Paradise Ducks, Spotted-billed Ducks, and Pekins.

Dorkings filled four good classes. The cup for cocks went to the first Silver-Grey, a magnificent bird; second was Mr. Boissier's well-known cockerel, now overshadowed; third an old bird, which would have been easily beaten by the very highly commended cockerel had not the latter had his comb apparently pecked by a hen. In hens the first Birmingham pullet was first, the Birmingham cup hen, not now looking her best, second. The first and second Dark cocks were grand Dorking-shaped birds. In hens the cup and second were birds such as are seldom seen side by side, all the finer probably from the fact that their owner does not now often show; they are rather lighter than the fashionable colour; third a rich Dark hen with good white feet.

Brahmas.—The first Light cock was very good, free from yellow tinge which so many had; second and third were also fine birds. The hen class was a large one. Several well-known winners were left out for poor or dirty condition, and one Birmingham winner for having a slipped wing. First was a capital hen all round; second good too; third magnificent in size, but the sap in her feathers gave her a yellow tinge. In Darks the cup cockerel was as grand a bird as we have often seen; his comb is a trifle too high, otherwise he is nearly perfect. Second a good cockerel of Mr. Lingwood's, third a fine old bird rather out of condition. From the middle of the class the Dark Brahma hens were in a

miserable light, close to the ground and in a narrow alley. The Judge took a very long time in making his decisions in this class and in all the Cochins classes, having all the better birds carried for comparison to a lighter place. The cup hen is very clear and dark in pencilling and good in size; Mr. Lingwood's second very good in pencilling too, though not quite so distinct and grand in shape; third a hen which would in most shows command a first prize.

Cochins.—Cup and second in Buff cocks were Mr. Procter's two redoubtable champions. Among the highly commendeds was the Palace cup cockerel, beautiful in shape but too black in tail. In hens the first-prize bird was in our estimation nearly a model of Cochins shape and perfectly even in colour; second an enormous old hen; third and very highly commended Mr. Procter's well-known hens, grand in shape, but not equal in colour to the first-prize bird. Any other variety.—First a White cock as good as we ever saw, a bird which could hardly be beaten for a cup save by the wonderful Buff cock here shown; second a fine old Partridge first at Birmingham; third a very good White, claimed at ten guineas. In hens cup and second were magnificent Whites. The cup bird was best in leg feather, but the second, the Oakham cup bird, was in shape quite as good if not better; third a Partridge, the Palace cup bird we heard. Several very dark Grouse hens were shown in this class.

Game.—The Game classes were excellent, all the best-known winners appearing. The cup for cocks went to the now-famous hundred-guinea cockerel, now in the hands of Mr. Lyon; he hardly looked his best. The first Black Red was particularly good. The first Brown Red cock, the Birmingham cockerel cup-winner, was in grand trim; second a good adult cock. The cup for hens went to the first Brown Red in a class of nineteen, a very gamey bird. Duckwings and Piles both had two classes. In the Pile cock class both the Birmingham cock and cockerel were in the list. The first Pile hen was a very remarkable bird. The first Duckwing hen a very good bird of the year.

Hamburghs were splendid classes. Unfortunately some of the Blacks and the Golden-spangled and pencilled were in a very bad light. The cups went to a splendid Gold-pencilled cockerel and to a matchless Silver-spangled hen. First on the list came Gold-spangles. First cockerel was a well-marked bird, poor in tail. The first hen had the even moderate-sized mooning which we much admire. The cup Golden-pencilled cockerel is very even in colour and splendid all round; second apparently had a good honest comb. It was impossible to see their tails. The first hen had very rich ground colour, but barring on breast and tail weak. The Silver-spangled cocks were very good. The first-prize bird fine in carriage, with lovely sickles and even mooning. The three winning Silver-spangled hens were as good as we have ever seen. They had the advantage of an upper row, and so of some light. The lustre of the cup bird's moons was wonderful. Silver-pencilled cocks were an even class. The first had a beautiful tail, not a good comb. In Silver-pencilled hens the winners were all good, but the first-prize bird far ahead, being well marked and with a clear hackle—a combination now rare. Blacks were capital. First and second cocks were both good in carriage and with natural combs. Mr. Serjeantson's highly commended cockerel the greenest in the class, but with a little tinge on lobes. The first-prize hen was lovely, her owner's other bird almost better. Mr. Long's second-prize hen, too, very lustrous.

Spansh.—The cup cock had a very smooth face and good comb; second a longer but not so well-shaped a face. The first hen had an extraordinary face and a most cock-like appearance; she might certainly do duty for a cockerel early in the season; second had a fine face but too heavy a comb.

Leghorns had four well-filled classes. Time failed us to criticise them all; a glance showed us that the cup went to a beautiful White cock.

Houdans.—Cup went to a magnificent cock. He showed yellow in tuft and neck hackle, still we thought the award a good one; second had an ugly comb, and being in a small pen hardly showed himself off. We much admired Mr. Hibbert's very highly commended bird. The first hen was grand in all points; second had a beautifully formed tuft; third good with a handsome beard.

Crève-Cœurs and other French.—First cock a noble Crève, but with a little white in crest; second wonderful in lustre for a Crève, with a large but irregular crest; third a big La Fleche. The winning hens were all good Crèves in a bad light.

Any other Variety.—First in cocks a capital Silver Poland, second a White-crested Poland, third a fair Andalusian. The cup went to a grand Silver Poland hen, second a Golden Poland, third a Sultan.

Bantams.—Game Bantams had four classes. The cups went to the Black-breasted hen, the best by far in her class, and to the Pile cock, as good a bird as one could wish to see. The winning cock in the Any other Bantams was a Pekin, second a Black, third Mrs. Brasse's Japanese. Sebrights were fairly beaten for once. In hens first a good Silver Sebright, though we preferred Mr. Leno's highly commended bird; second a very good Black, third again a Black. The Selling classes contained some bargains, espe-

receive the same uniformly firm treatment every day of her life, and her habits soon conform to the daily routine. The complaints of kicking cows generally come from farmers who own but two or three cows, and not from those who make a business of handling them. There are, I suppose, occasionally confirmed kickers who have no business in any respectable herd, and that should be turned into beef immediately.—L. S. HARDIN in the *Ohio Farmer* (abridged).

—WOOD ASHES with the bits of charcoal in them, and coal ashes too, are excellent for the fattening pigs. Pigs cannot stuff themselves, week after week, without their stomachs getting out of order, and the bits of charcoal check acidity and regulate them and help to improve their appetites. We think our pigs cannot get along without the little pits of ashes in one corner of the pen to root over and pick the charcoal out of. It is their dispensary.—(*New York Rural*.)

—THE *Agricultural Gazette Almanack*, besides furnishing much useful tabulated matter and a monthly calendar of operations, contains special articles on prominent topics of agriculture, portraits and biographical notices of eminent agriculturists, also illustrations of the prize oxen of the year. It is a very useful publication.

—MR. G. FRY, of Navestock, Essex, has made some curious bets. Restricting himself to seed to be procured from Messrs. Carter & Co., he has laid £10 each against four other farmers that he will grow two acres of mangels against two acres grown by each of the others, who are all to obtain their seed from Messrs. Sutton and Sons. He has also made a bet of £100 with Mr. J. H. Smith, one of the four, that he will beat him.

—AN excellent authority has written as follows on feeding confined poultry. As it stands to reason poultry in confinement get no food but what is given to them by hand, it will always be difficult to keep them as economically as those that have their liberty. First, provide good food—bad corn and meal are always dear. Feed entirely on ground food, and, as we have often explained, feed only so long as the birds run after it. When they become indifferent they are not hungry. The most economical plan is, meal in the morning, whole corn at mid-day, and meal again in the evening. If this is correctly and carefully followed you will be surprised at the small cost of your poultry.

NATIONAL PERISTERONIC SOCIETY.—The annual Show of the above Society at the Crystal Palace is fixed for January 8th and 9th. A large collection of birds is anticipated, an unusual number of the members having signified their intention of exhibiting on this occasion.

EGGS IN WINTER.

WE cannot give a better reply to Mrs. L.—who desires eggs “when they are dear,” than the following, which has been written by one of our most experienced correspondents.

It may safely be said that in almost all the weathers fowls will lay at a certain age. This does not imply that they all do so at the same age. Some breeds are more precocious than others. Thus Brahmas and Cochins lay at from eighteen to twenty weeks if they have been well kept, and they will continue to do so. Good young pullets of these breeds will lay forty or fifty eggs at the time of year when they are most valuable. Say, for argument's sake, each lays forty, and they make 8d. each, produce 10s.; the pullet is eight months old, and has cost 8d. per month ever since she was hatched—cost, say, in round numbers, 6s. The hen may now be sold for 2s. 6d., or she may be kept to rear one of the broods that will form the laying stock for the next winter.

It may be that some may be disposed to think our descriptions visionary, or that we draw on imagination. It is not so. The secret of the profit is this: Those who will not sell when the use of a bird is lost for a time are not to look for profit, because they are following a hobby. The first sound that indicates broodiness in the sentence of death; and the place will remain vacant till the late autumn, when some pullets will be introduced in order that they may get accustomed to their place before they begin to lay. It is the fate of all food-producing animals to be weighed against their own produce, and whenever their consumption would equal or exceed their contribution they are doomed to die. They are not only feeding men, women, and children with their carcases, but that production of food for others must be the livelihood of their owners. Our egg-producing hens are then subject to this test, and he who is determined to make them profitable thus tries them:—“Two good hens, very good hens indeed, cost 7s. two months since. Have laid seventy-five eggs, sold for 25s.; cost 8s. 6d. keep: 14s. 6d. profit. Won't lay any more at present. Will make 2s. 6d. a-piece to sell. Better sell them.” It is in vain the wife says it is too bad to kill the poor things, and the little daughter stipulates for the same one. Nothing is more inexorable than money-making. Everything but honesty falls before it. It requires no small firmness on the part of Paterfamilias to deny

the loving request, and to be deaf to the prayers of wife and daughters, when interest says “kill,” and they say “spare.” The poor man's patience, too, is often sorely tried; for if there is a pet among the hens it is generally one that has, by some accident, lost a leg, or as a crossed bill and is unable to pick up food, or carries its tail on one side.

But these hens are killed because the food for them must be bought. The same cause for killing does not exist in a farmyard, because, whether rightfully or wrongly, it is supposed fowls cost nothing to keep in a farmyard, and because there a profit is made of chickens.

RABBIT BREEDING.

THE Rabbit is extremely prolific, and the multiplication that takes place in the species is very large. It is fortunate that many things war against the lives of the little animals, or we should be completely overrun with them. As it is, what with the damp and cold, and several animals to prey upon them, their fecundity is only sufficient to keep the warrens and fields stocked with them. The Rabbit does not breed so rapidly in captivity, but even in that state the powers of reproduction are simply extraordinary. A doe will have six or eight young ones in a litter, and as many litters in a year, so that each doe may produce from eighty to ninety or even a hundred young Rabbits in the course of the year; and when it is calculated that each pair of the young will be able to breed at six months old, and that each will probably bring forth its ninety or more young, the rapidity of the increase can of course be easily understood.

The doe Rabbit arrives at the age of puberty when about eighteen or twenty weeks old, although sometimes the change does not occur till the twenty-fourth week or even later. No good fancier will, however, allow a doe to become a mother at anything like so young an age. The exact age at which Rabbits should be paired must be regulated somewhat by the time of year at which they were born. If born in the spring they should not be paired before February. If, however, the doe Rabbit was born in the summer, say in June or July, they may also be paired in February. They will towards the end of the latter month be seven or eight months, and will have the prospect of the full breeding season before them. Rabbits born in the spring are always the best for breeding, as they are stronger and more healthy, and they also come in season nicely for the next spring. Does for litters thrown in the autumn must be kept back till late in the next spring or even into the summer, so that they may have attained the age of at least nine or ten months. Sometimes it is recommended to leave them till they are a year old. This we hardly think necessary unless they were born in the early spring, in which case if they were put to the buck when ten months old it would be in the depth of winter, a very bad time indeed. Sometimes a doe resolutely refuses to receive the buck. If she be put in a hutch within sight of him she will be likely to come on, or sudden change of diet from plenty to scarcity, or *vice versa*, will sometimes move them. Unless a doe of this sort is extremely valuable she should not be kept for breeding owing to the great trouble she will cause. If, however, she is exceptionally valuable, of course extra trouble must not be grumbled at. When the time for kindling has nearly expired the doe will begin to feel a considerable thirst, and to alleviate this—which is necessary to keep her cool and from eating the young—a little water or milk should be given her twice a day, beginning a couple of days or more before the period has expired. About the same time the doe will begin to exhibit considerable uneasiness, and will tear-up her bedding and carry it about in her mouth. This is often given as an infallible sign of pregnancy, but it is not so, as some does do it when their constitutions are ruffled in any way. But if she adds to the bedding fur or fluff from her own body then the fancier may be justified in considering matters fairly safe. It is no distinct guide as to time, because some does commence preparations several days, sometimes even a week before the expiration of gestation, while others do not make any preparations till they find the time quite close. Often the nest is made and the young born in a single night. As soon as there is reason to expect the young ones in a day or two it is a good precaution to cover the front of hutches with sacking so as to keep the cold out, but not so tight as to make the air offensive. Great quiet must be observed, as the slightest noise or even the sudden appearance of a stranger may cause the young mother either to destroy or neglect her offspring. With care 99 per cent. of the litters should be successful.—G.T.A.

DEATH OF MR. H. C. HENNING.—We have to record the death of Mr. H. C. Henning of Chiswick. His cheerful face will be greatly missed at the forthcoming Peristeronic Show, of which Society he was a useful member. In a very short space of time he had collected one of the best studs of Almond and Mottled Tumblers in the kingdom, and was an earnest and liberal supporter of these varieties at our principal shows. His straightforward conduct and amiable temper made him a host of friends in the Pigeon world, who will greatly deplore his loss. Mr.

Henning had hardly reached what is called the prime of life, and appeared a few weeks back, when we had the pleasure of meeting him, in perfect health.

USEFUL PIGEONS.

SOME years ago I wrote somewhat as follows on the Carrier Pigeon. This Pigeon is essentially useful; not a show bird—not a bird of points and properties, but of utility. Call the bird the Persian Pigeon, or the Turkish Pigeon, or the Scandaroon, or the Bagatin, or the Horseman; the bird is one and the same,

perhaps some larger than others, but substantially the same. The bird was a bird of utility, and capable of being trained to greater utility, and naturally feather or shape, save as tending to utility, would be uncared for. The shape of these Pigeons was well suited to cleave the air; formed as we make the fastest boats, they were to other Pigeons—for example, the Runt—what the University racing boat is to a barge. These Pigeons had also in common, notwithstanding differences of name, more or less of naked lump-like flesh round the eyes and above and below the base of the beak. From these birds came, by care and selection and good judgment in matching, a florists' flower of Pigeons—

Fig 4.—THE CARRIER.

the fancy English Carrier, just as in like manner came the Almond Tumbler and the English fancy Pouter.

As evidence of the great utility of the Carrier I quote the following from the *Fishing Gazette*—"The experiment which was tried last year of employing Carrier Pigeons for the purpose of bringing early intelligence each morning from the fishing ground of the results of the night's labour is again being resorted to this season, and with the most satisfactory results. One of the birds is taken out in each boat in the afternoon, and after the nets have been hauled on the following morning and the extent of the catch ascertained the Pigeon is dispatched with a small piece of parchment tied round its neck (?) containing information as to the number of crabs on board, the position of the boat, the direction of the wind, and the prospects of the return journey, &c. If there is not wind to take the boat back, or if it is blowing in an unfavourable direction, a request is made for a tug, and from the particulars given as to the bearings of the craft she can be picked up easily by the steamer. The other advantages of the system are that, when the curers are apprised of the quantity of herrings they may expect, they can make preparations for expediting the delivering and curing of the fish. Most of the Pigeons belong to Messrs. Moir & Son, Aberdeen. When let off from the boats the birds invariably circle three times round overhead and then sweep

away towards the land with great rapidity, generally flying at the rate of about a mile per minute. Two superior birds in Messrs. Moirs' possession have occasionally come a distance of twenty or twenty-five miles in as many minutes. Another of Messrs. Moirs' Pigeons flew on board the Heatherbell on Tuesday afternoon off the Girdleness bearing a slip of paper containing the intelligence that the boat from which it had been dispatched at 11.54 had a cargo of twenty-five barrels of herrings. The Pigeons require very little training, and soon know where to land with their message. A cote has been fitted up on the roof of Messrs. Moirs' premises at the quay for the accommodation of the birds, and they invariably alight there on their return from sea." Even a non-fancier will, I think, own that the above is a very interesting use to which the Homing or true Carrier Pigeon is being put. Such birds can scarcely be too generally cultivated.—WILTSHIRE RECTOR.

Another writer has observed :—

"The Carrier Pigeon is not only a useful but is a graceful bird. Although he does not show to advantage at exhibitions, yet it has been well said that no bird ever deserved more truly to take prizes than some of those Carriers exhibited during the last few years. There has been a gain in the size and strength; both were lacking a few years since, when the birds shown were too

small and pretty; now it is not so. Whatever doubt there may be as to which variety of fowls should head the prize catalogue (and committees appear to take different views), yet no doubt exists in any Pigeon fancier's mind that the kingly Carrier must always be placed first. Apart from the different points, there is the Carrier look which marks the first-class bird. He looks not a creature of feathers, but like a piece of black marble.

"This useful and stately bird is well represented in the accompanying engraving.

POULTRY FOR PROFIT.

ALTHOUGH both eggs and fowls may enter into calculation, yet precedence must be given to one or the other; and in every case, when poultry is intended to be something more than a recreation and to pay as an investment, it is necessary to know something of the neighbourhood, its wants, and its markets. In some places eggs are most wanted, in others fowls. The knowledge of these things must dictate the breed that is to be kept. The produce of birds may be considered as a certainty if they are properly chosen and judiciously fed; but almost every breed has some peculiar characteristic. Thus, if the establishment were in a neighbourhood where an egg is an egg, and all that is required is a certain number in exchange for a shilling, Hamburgs or Cochins would be the proper birds, especially the former, as they are small consumers of food. If it were a neighbourhood where ladies marketed, and where things are carefully looked at and studied before they are bought; where, after asking the price, they promise to call again, and intend to do so, we should keep Spanish, as the size of their eggs would always command a sale in preference to any others. If fowls were wanted for the table, and good ones were sufficiently appreciated to cause buyers to give a little more for a better bird there, we say keep Dorkings as table fowls. These explanations must of necessity lack interest for the general reader, but they are essential to be considered by those who are looking for profit from their poultry.

We will suppose it is only required to produce eggs. Cochins, Brahmas, or Spanish will do in a small space, and a hundred of either may be kept on an acre of ground. But as neither breed nor age will produce eggs from unhealthy birds, it will be necessary to take every pains to keep them in a satisfactory state. The three breeds we have named bear confinement well, but it will happen that they flag a little at times. Any precaution is then worth adopting. Let us suppose one hundred hens on an acre of ground. It would be well to divide them into four sets, each with a different run, and, above all, a different roosting-place. More than half the disease is got by roosting too closely in small buildings. Most diseases are contagious or infectious, and for this reason the division into four parts offers security which should not be neglected. It will be necessary every year to have young birds, and these must be bred on the premises. Two acres would require to be set apart as rearing-ground for chickens. Houses, yards, &c., would occupy half an acre. Four hundred hens might be kept, then, on six acres and a half in good laying condition. They would have to pay their expenses by their eggs; but as it would be necessary to breed many, and as we advise beginning with pure birds, we believe that every year some chickens might and would be selected which, at exhibitions or by private sale, would make prices that might prove very remunerative. We have here put the smallest possible space on which we think the birds could be kept, and they would unquestionably do better if they had more room.

It will be very difficult to name the quantity of food they will consume; but it should be carefully seen to and none wasted. In nineteen out of twenty of the yards where fowls are kept on a large scale half the food is wasted, and another portion is uselessly expended in trying to make the fowls eat more than they require. The supply of eggs must be kept up during the year, as the largest profit will be made when fewest eggs are laid. Really new-laid eggs in the winter will make 8d. or 4d. each for weeks, and for a long time they will make 1d. each. This last is a remunerating price. We believe it is possible if not easy to make fowls pay by eggs, but only where there is personal superintendence.—B.

BEE-KEEPING PAST, PRESENT, AND FUTURE.

SOME forty years ago the Royal Adelaide steamer from Leith landed me in the streets of London one Sunday morning about ten o'clock. What a big hive with a young queen (for she was young then) was London! I went there to seek work and make my way in the world. On the evening of the day after my arrival I found my way to Clapton and asked Mr. Low if he could assist a poor Scotch gardener just arrived. He sent me at once to Lord Mansfield's gardens near Hampstead, and there I pitched my tent for two years. My knowledge of bees, their management and natural history, was gained in my youthful days in Scotland before I had seen a book on bees. I am now thankful it was so. On a bookstall in London I saw Huber's book on bees and bought

it. It is a well-written book by one who was an enthusiastic lover of bees and an industrious student of their natural history. Unfortunately Huber had lost the use of his eyes, and had in a great measure to depend on his faithful servant and assistant Francis Burmens to carry out his suggested experiments and observations. Huber's book does not treat on practical and profitable management. At the end of two years I went to live near Barnet, where I found some bee-keepers, who were not bee-masters, being ignorant of any and all systems of management. It struck me that the English bee-keepers were in darkness and had made no progress at all from time immemorial. Dr. Bevan's book, "The Honey Bee," had fallen from the press, and was published at 10s. a copy. I bought a copy to see if the doctor was in advance of all around him, but found that his book was a mere reflection of Huber's work on the habits of bees, and contained no evidence of ability to teach the first principles of practical and profitable management. Dr. Bevan had not had experience enough amongst bees to produce an original and enlightening book, and bee-keepers received no healthy impulse from his teaching.

During the next thirty years other bee books appeared, most of which were compilations without influence. At last Dr. Cumming—the great writer on unfulfilled prophecy and "The Times Bee-keeper"—sent out a big book on bees, which to juveniles was a readable work, but not a safe guide to profitable bee-keeping. During the thirty years now noticed bee-keeping in England made little advance, if it moved at all. Everywhere we went we found bees without culture, like a neglected garden.

In Scotland, or some places of Scotland, things were very different. In my native parish and other parishes in Lanarkshire bee-keeping had been in full swing for more than sixty years. My father, who was a common labourer, banked £350 before his marriage, and this, I believe, was mostly realised from bee-keeping. He was the leading spirit there, and probably the most successful bee-keeper in Scotland. His example and success encouraged others to follow in his course. If I look back fifty years I see shoemakers, tailors, grocers, weavers, and labourers who never read a book on bees managing theirs with great and encouraging results; and, moreover, with nothing but straw hives they had gained a comprehensive and accurate knowledge of the habits of bees and the internal workings and economy of hives. Compared to England they were at least fifty years in advance.

The Rev. G. J. Wood, who has written many popular works on natural history, wrote one on bees some years ago. In this book Mr. Wood tells all he can about the anatomy and habits of bees, and then says that someone else must come after him to teach how they are to be managed. This admission of Mr. Wood's is an evidence of his wisdom, and brings to our remembrance the wise remark of an old heathen philosopher, Pathagorus—viz., that "men ought either to be silent or say what is better than silence."

Many teachers have appeared amongst us since Mr. Wood's remark was made. Mr. Woodbury was an able writer, and did much to enlighten the bee-keepers of his time by unfolding the mysteries of bees and stimulating attention generally to the subject of apian science. In the midst of his days he was taken from us. He was an honest and enthusiastic student of bee history, and his pen was that of a ready and accomplished writer.

Mr. George Fox of Kingsbridge, Devonshire, has been a very successful bee-keeper, and has done excellent service by exhibiting his grand supers of honeycomb. We are thankful for what he has done, and hope that he will in coming years go beyond his former examples of successful bee-keeping.

The "RENFREWSHIRE BEE-KEEPER" has done capital service by recommending the Stewarton hive and recording his success with it. The bee-keepers of Ayrshire, particularly about Kilmarnock and Stewarton, have used this hive for many years with considerable success. There I believe the "RENFREWSHIRE BEE-KEEPER" learned how to work and manage it. The results realised by himself on two or three occasions have been extraordinary.

Mr. Abbott of the bar-frame school is, too, doing a good work by exhibiting his ability and expertness in manipulating bees and the contents of their hives. He thus shows the public that bees and frames may be removed from one hive to another with ease and without much risk or danger. Object lessons are always valuable. In the bar-frame school we have now many clever men, from whom I expect great things. Some of them are in the top class, and well merit a certificate of competency and efficiency in the work of teaching others.

Mr. John Hunter and Mr. Frank Cheshire, though comparatively young men, and perhaps young bee-keepers, are very clever men of this school, and accomplished writers. They have already sent out into the world works on bees. Mr. Hunter's is a book chiefly made up by quotations. Mr. Cheshire is a scholarly writer. His book is one of condensed thought embodied in language rather too high for the bee-keepers in the country—it is not a book for the masses. Though both gentlemen appear to me to lack some more practical experience I am pleased to give them a good mark and put them in the top class. They have a brilliant future

before them if they study bees and bee-keeping in their gardens and not in books.

Mr. George Campbell, New Pitsligo, Mr. A. Cockburn and Mr. James Shearer in the Huntley district, all in Aberdeenshire, and many others in Scotland, deserve honourable mention here, for they are most active and successful men with bees in straw hives, and by pen and example they are encouraging the bee-keepers in the north. Mr. Campbell, a veteran bee-keeper, had a hive a few years ago which, with its swarms, reached the great weight of 873 lbs. gross; and one hive of Mr. Shearer's gathered 10 lbs. in one day.

Ever since my arrival in England I saw that a practical treatise on bee-keeping by a practical man was needed, and so far back as 1844 the late Dr. Lindley advised me to write one, and which he said might be published at the office of the *Gardener's Chronicle*. My life for many years afterwards was so eventful and harassing that I abandoned all idea of writing a book. Some small treatises on bees fell from my pen during the next twenty-five years, but they did but little good. My balance sheets of bee-farming which appeared in *The Times* roused more attention. In 1866 I happened to pass through Edinburgh, when Messrs. Blackwood and Sons engaged me there and then to write and prepare for the press "The Handy Book of Bees" by purchasing the copyright. Three years after the bargain was made—in the winter evenings of 1869—I wrote the book and handed the manuscript very early in 1870 to the publishers, and thus fulfilled my engagement. It appeared in print shortly afterwards, and received the approval and commendation of about seventy of our leading newspapers and periodicals. More to my astonishment, perhaps, than to anybody else, its circulation and influence have probably been greater than those of any other book on bees yet published; and for the sake of the public and the publishers I am gratified that so many editions are called for and absorbed, and better still that the work has given light, confidence, and happiness to thousands of its readers, both rich and poor. The weakness of this personal reference will be excused if the reader will bear in mind that I have no personal interest in or profit from the sale of the book.

It was my intention to notice in this letter the Bee-keepers' Association and other matters and movements, but will pass them over and come at once to bee-keeping in the future.

We look forward hopefully to the future. During the last ten years many English bee-keepers have made great progress. Their past success has given them confidence and encouragement. Their knowledge is power. They mean to advance, not by following, but by moving to the front ranks. Nothing but weather can prevent these bee-keepers from succeeding. The models of the past, fine as they certainly are, are not to remain the models of the future. The introduction of artificial comb foundations will give great help and impulse to the practice of supering. By their use I believe we shall have harvests of honeycomb such as have never been known. Swarms in other counties besides Lanark and Aberdeen will sometimes rise in weight to 150 lbs. Light will dispel darkness. Bees in the gardens of the cottage homes of England will be a perennial source of pleasure and comfort to the inmates. Bee-keeping in the future will be an uplifting boon and blessing to hundreds of the homes of the working rural population of this country, sweeping from the brows clouds of sorrow, and from their hearts the pressure of care and poverty. What a satisfaction it is to an honest working man to feel that he is in possession of a power and holds a position to keep the wolf of want from his home!

In the arena at Olympia, near Corinth, in which the celebrated games and races came off in olden times, stood three stone pillars. On the pillar facing the starting-place was written the word "Excel," on the second pillar was the word "Onwards," and on the third stone (turning post) were written these words: "Finish the race;" and around these stones the best blood of Greece competed for the mere honour of victory. To bee-keepers of every school of thought and practice, to men with Stewarton hives, to men with bar-framers and men with straw hives, to men of the mansion and men of the cottage, to men of England, Ireland, and Scotland, and to ladies and gentlemen and all readers of the *Journal of Horticulture*, I cordially recommend the adoption of the Grecian mottoes, "Excel," "Onwards," "Finish the race;" and I wish all a happy and prosperous new year.—A. PERTTIERBW.

OUR LETTER BOX.

MR. R. S. S. WOODGATE (*Exhibitor*).—We cannot give you any information on the subject. Mr. Woodgate does not now belong to our staff.

BRAHMAS AND COCHINS (*Fulham*).—Brahma fowls wander from home more than Cochins, but they are not in the habit of staying away to lay. They may be kept in confinement easily, even in a very small place.

LOSS OF FEATHERS (*D. D.*).—A feather pulled out of the tail of a cock or hen will grow again in a short time. The loss of both sickle feathers would be a great disadvantage to a bird, but it would not be a disqualification.

REMARKS.

19th.—Foggy day, no sun; slight rain in evening.

20th.—Thick fog in morning, clearer afterwards, but no sun.

21st.—Bright in the early morning, dull by 9 A.M., and continued so all day, with damp mist and occasional drizzle.

22nd.—Rather warmer, overcast, and dull; rain at night.

23rd.—Very fine morning and brilliant day, very hot sun.

24th.—Overcast, but no rain; colder at night, with much wind.

25th.—Thick white frost, fine day, snow began about 9 P.M., and during the

night fell to a total depth of about half an inch.

Very high barometer on 26th, from which point it fell steadily to 24th, but with very little rain and scarcely any wind until the night of that day.

Note.—There are two correct readings in the above table which look incorrect. Upon the 19th it is reported to have been colder in the sun than in the shade; that is true, because there was no sun, and there was slight radiation from the sun thermometer. Again, on the 20th it is shown that it was 1.6° hotter on the grass than in the air; this was due to there being no radiation during the night and to the warming of the grass thermometer by the soil being hotter than the air.

26th.—Ground lightly covered with snow in morning; fine, cold, sunny day, and clear at night.

27th.—Clear, bright, cold, day.

28th.—Fine cold morning, dull and rather foggy afternoon; snow began at 5 P.M. and fell heavily during the evening, but rain followed and melted it all.

29th.—Rainy morning, temperature 20° hotter than yesterday, fine at times, but a very damp day.

30th.—Very dull day with rain at times.

31st.—Colder, bright, clear, and fine.

Jan. 1st.—Foggy morning and dull all day; spots of rain in evening.

The first three days cold and bright, afterwards warmer. The total rainfall of 1877 was 28.17 inches, or about 12½ per cent. above the average.

—G. J. SYMONS.

COVENT GARDEN MARKET.—JANUARY 2.

OUR Market is now beginning to look very bare, and with business quite we have scarcely any remark to make. Good late-keeping Apples, such as Blenheim, Wellingtons, and Nobes, are being sought after and will now well repay themselves. Cobs with a short stock on hand are quiet.

From observations taken near London during forty-three years, the average day temperature of the week is 42.0°; and its night temperature 30.0°.

CAPE HEATHS.—No. 1.

JANUARY.

I say "Cape Heaths" to distinguish the particular kinds cultivated in the greenhouse from the hardy species which are grown in the open borders, these being natives of Europe; but although indebted to that portion of the African continent known by the name of the Cape of Good Hope for an immense number of very fine species, many of the most exquisitely coloured and most popular kinds now grown are varieties produced at home, the result of cross-breeding. True, *Ericas* in a state of nature are found only in Europe and this particular point of South Africa, although other members of the order have a wide distribution; recently indeed it has been asserted that an English *Erica* has been found growing wild in North America. This, however, may have been introduced by the British settlers; at any rate it is a disputed question, and as we have no means of arriving at a satisfactory conclusion it need not be carried further in this place.

Heaths are generally (and it must be admitted with some truth) considered rather difficult to grow, and this has been scored down as a black mark against them; but the chief point connected with their successful cultivation lies in strict attention to their peculiar requirements. Another black mark against them is that they are slow-growing, and require several years to become large specimens; but although this is in reality true, everyone does not require large specimens, whilst even as young plants the majority of them bloom profusely, and are extremely handsome, and do not so soon as the *Geraniums*, *Fuchsias*, &c., outgrow the bounds, which to those whose space is limited is an item of considerable importance.

Heaths are somewhat liable to die suddenly, and therefore a few young plants should be added to the collection from time to time; but if the plants are judiciously watered and not overpotted, the death-rate will be reduced to the minimum. When the plants show signs of growth any that want more pot-room should be shifted in order that the roots may at once work into the new soil, as we consider this better than repotting periodically. Respecting the propagation of Heaths we shall say nothing, as it will be much cheaper even to the smallest amateur to purchase young plants, say in 60 or 48-sized pots, than to attempt the propagation of them at home, although all who grow a few kinds may always find a pleasant occupation in hybridising and raising new varieties from seed, and it may be that some new and desirable form may reward the operator, whilst worthless kinds should at once be discarded.

In commencing the cultivation of this handsome and showy family of plants we may seasonably give a selection of the best kinds flowering in January.

Erica gracilis.—Of this species there are two varieties, one which commences blooming about October and continues to about the end of the present month is called *E. gracilis autumnalis*, and another, which will soon succeed it, is

called *vernalis*; saving the difference in time of flowering there is little to distinguish them. This kind is very ornamental as young plants grown in 48 or 32-sized pots, when they may be used for table decoration or as window plants, serving to make the more sober ornamental-leaved plants gay by contrast, and thus form a welcome addition to our homes during the dull winter months. It is an erect-growing species, the leaves being smooth, small, and linear. Its flowers are small, reddish-purple in colour, and produced in the greatest profusion upon all the little branches, thus forming long and dense spikes which are very ornamental long before the blooms are really open.

E. hyemalis.—Like the preceding, this belongs to the soft-wooded section, and is extensively grown for table and indoor decoration. At this season it also makes a very effective object grown into a medium-sized specimen, and is invaluable to cut from; for as the plant must be cut-back hard after flowering, it is not detrimental to cut from it when flowers for vases or bouquets are required. The leaves are linear acute, clothed with short hairs, and dark green. The blooms are bell-shaped, and when well exposed to the influence of the air the lower half is deep rosy pink and the mouth white, but when kept in a confined atmosphere they become wholly white, or but slightly tinged with pink at the base. It should be encouraged to grow freely, when the whole length of the dense leafy spikes will be covered with bloom.

E. Willmorei superba is a fine robust-growing soft-wooded Heath, similar in general habit to *hyemalis*, but larger in all its parts. The flowers also resemble the last-named kind, but the bells are much longer. It should be treated in the way recommended for *E. hyemalis*, when it will be found to come into flower just as that kind passes away, and thus form a good succession to it.

E. mutabilis.—This is a perpetual bloomer, we therefore introduce it in the first month. It is a rather slender-growing plant, and seldom well furnished with foliage, but its bright flowers are very attractive; and as the plant really requires constant cutting to keep it down, the blooms may be used with much advantage for bouquets, &c. The leaves are bluntly linear, hairy, and deep green. Flowers produced in terminal umbels, tubular, fiery red in colour. This species delights in a dry and airy atmosphere; in other situations it is very apt to become disfigured with mildew both in summer and winter.—W. H. G.

VINE-BORDER COMPOST—BONES, CHARCOAL, AND WOOD ASHES.

I AM not greatly surprised that Mr. Taylor should have required more explicit information as to the proportions of cow dung and loam that had been recommended by "A KITCHEN GARDENER," and which that cultivator has now repeated in terms which cannot be misunderstood. "Three cartloads of loam, one of cow dung, and one of wood ashes, with a bushel of smashed bones to every cartload of the compost," is the formula submitted by "A KITCHEN GARDENER." In such a compost he intimates that he "has grown as fine Vines as he ever remembers seeing." I will

admit that he has grown excellent Grapes in that compost, still I cannot think it one that should be hastily adopted. I should not hesitate to adopt the mixture recommended provided, and this I hold to be highly important, the loam was of a poor, light, sandy nature, such as prevails in upland districts where sheep will thrive fairly well, but where bullocks cannot be fattened without a liberal allowance of "cake." I have observed that the turf from bullock-fattening pastures will grow Grapes admirably without any admixture whatever; but on chalky uplands, where Trefoil and Daisies preponderate over Buttercups, a manurial addition becomes necessary to the turf to grow good Grapes; they then want dung, just the same as bullocks require "cake" on such feeding-ground.

To add cow dung and wood ashes in the proportions named to loam already "fat" I should not only deem unnecessary, but almost dangerous, especially in wet districts. Loam of the character alluded to is naturally retentive of moisture, as also is cow dung, while wood ashes have a powerful affinity for moisture; therefore such a border for a low-lying district having a heavy rainfall I should consider too moist in its nature and close, even adhesive, for Vines. If the loam was of a decidedly fertile character, and taken from a field or district where the farmers grow six quarters of Wheat per acre, I should exclude cow dung entirely from it, but would retain the wood ashes and bones, reserving the dung for surface-mulching. It is loam of this nature that Mr. Taylor probably has at his command, and which grows such good Grapes with the homeopathic admixture of a bushel of bones to fifteen cartloads of the loam, and he would probably have grown them equally good if the bones had been excluded altogether, for there cannot be much virtue in such an infinitesimal proportion of them. If, on the other hand, the loam was taken from a district where only five quarters of Barley can be grown by the farmers instead of six quarters of Wheat I should consider Mr. Taylor's simple mixture altogether too weak for Vines, and should deem a liberal admixture of cow dung very valuable. Thus the statements of the two cultivators, who rank amongst the best in Britain, which at the first glance appear so antagonistic, become reconcilable.

I know of no term as commonly employed in garden literature so indefinite as "loam." It includes soil of the most poverty-stricken character and soil of the greatest fertility. I have had loam carted for Vine-border making in which it was impossible to grow Grapes satisfactorily without a liberal admixture of manure, and where one-third of decayed cow dung would have been hailed with something of the same satisfaction that a convoy of provisions would have met with at Plevna a month ago; and, on the other hand, I have had loam that did not require a particle of manure mixed with it for growing heavy crops of Grapes. But I have never yet seen loam to which I would not have added bones, wood ashes, and charcoal for Vine-border making. These ingredients not only contain a very large amount of food essential to the Vine, but they have a mechanical value which must never be overlooked in the preparation of composts.

If the Vine is analysed it will be found to contain a considerable quantity of phosphate of lime and a still greater quantity of potash. If bones are burnt a residue remains of three-quarters of their weight of earthy substances, nearly all of which is phosphate of lime; if wood ashes are analysed their chief constituent is found to be potash; therefore the value of those ingredients is established. Ammonia is of course indispensable for the sustenance of the Vine, and no substance in nature has much greater power of absorbing it than charcoal. A lump of charcoal is a storehouse of Vine food, and several lumps in a flower pot and bushels in a Vine border cannot fail to be highly beneficial; yet not more so (but beneficial in a different way) than bones and wood ashes. When Mr. Taylor says that "charcoal is decidedly preferable to wood ashes," it is tantamount to me saying that beef is decidedly preferable to Potatoes: the fact is that both are essential, and cannot properly be placed against each other for purposes of comparison.

But I would not have Mr. Taylor or my readers generally to conclude that my reasoning is solely derived from theory. I know very little about horticultural chemistry, but have endeavoured to become acquainted with some of its rudiments for the purpose of testing them in the laboratory of practice, and I have found after careful experiments that the application of the ingredients named are first-rate aids to Vine culture both in pots and in borders; all of them are "decidedly" good,

but I do not believe there is a better or a best in the trio.—
A NORTHERN GARDENER.

A HORTICULTURAL RETROSPECT—1877.

THE beginning of the new year is a time when most people take a glance backward. There is a balancing of accounts, a taking stock of goods, and in every well-ordered mind a thoughtful looking-back as to our fulfilment of the varied duties which each one has to perform. Well for the happiness of those who can gratefully acknowledge to the Giver of all good that it has been a year of progress. While some, then, are anxiously scanning, after a year of great depression, their ledgers and bank books, I would just like to pass in review the past year as it pertains to horticulture. Others, as Mr. Luckhurst and "WILTSHIRE RECTOR" (to whom a brother's greeting) have done so; let me from my own standpoint do the same. Every little item of personal experience and opinion may add something to the general stock and help us on for the future.

We cannot look back on 1877 as a year marked by any remarkable event in horticulture, by the introduction of any startling novelty or any extraordinary gathering of horticulturists either at home or abroad; no year like that when Lillium auratum first took us captive, or the Great International Exhibition astonished those most *blasé* in horticultural exhibitions. I fail to notice, again, marked increase in taste, although I am convinced that taste does improve, not by leaps, but in a slower, more gradual, and therefore perhaps more satisfactory manner; nor has anything very remarkable in the way of cultivation astonished us. We have seen fine plants shown; but then we always see fine plants, and a few feet more or less, half a dozen more spikes of bloom than we have been in the habit of seeing, make no appreciable difference. We have seen old and practised hands retiring from the arena and their collections dispersed, but there are others to take their place. "*Le Roi est mort; vive le Roi!*" And while we may wonder why the fancy of some people should be directed into the channels they run into—while the florist wonders what on earth a man can see in a whole place full of ugly-looking succulents, and the Cactus-grower wonders why the florist should maunder over his collection of puny Auriculas, each according to his taste is following out that love of beauty (for beauty is manifold) which holds all alike entranced; and so horticulture grows by the varied loves of its votaries.

I have said no great gatherings of horticulturists took place in 1877. There was one which was intended to have been such—Carlisle. Every preparation had been made in the border city for it; its central position (although it seems a difficult thing for us in the far south to consider it central) was well adapted to make it so; but all was marred by the most wretched weather that ever disappointed the hopes of a committee, and I suppose for the future whenever we have to mark an unfavourable day it will be sufficient to say "It is not as bad as Carlisle." With many of the remarks of "WILTSHIRE RECTOR" on flower shows I thoroughly agree. My own observations you were good enough to insert some time ago, and they tend to much the same end—that flower shows do not generally pay, but that nevertheless they will continue to be held. Music is quite a legitimate addition to them, but some of the adjuncts sometimes allowed are, I think, more than questionable. However numerous may be the real lovers of flowers, in any one place they are not sufficient to maintain a society in any degree of efficiency; and therefore we may quite expect that if we make it attractive outsiders will come in to see and be seen, to hear good music, to meet their friends. It would, however, be unfair in looking back on horticultural efforts during the past year not to notice the vigorous attempts that have been made to create or revive an additional interest in some special flowers, notably the Rose, the Auricula, and the Carnation and Picotee.

The formation of the National Rose Society and the holding of its first exhibition mark a distinct departure in the cultivation of that universal favourite. It is true that the show was financially a failure, thereby confirming all that has been said about the support that the general public give to shows; and while the arrangements made for 1878 will ensure freedom from this, they will also tend to make the Society truly a national one. The determination of the Committee to hold two exhibitions, a metropolitan and a provincial one, will enable Rose-growers in all parts of the kingdom to compete; and if the season be a favourable one we may expect, I think, at the Crystal Palace such a Rose show as has never before been held, while we know that our friends at Manchester will

do all they can. Mr. Bruce Findlay is so practised a hand that all that can be done to give it *éclat* will be done, and we hope to surprise the Manchester folks with such a display as they have never seen. The attempted revival of a taste for the Auricle and Carnation and Picotee is due mainly to Mr. E. S. Dodwell, and it came none too soon. I have a list before me of the growers and exhibitors of Auriculas forty years ago in and about London, and it amounts to nearly forty, many of them indeed humble men, but with the same kind of love and energy that distinguished the artisans of Lancashire and Yorkshire; I wish I could see a similar number now. The season was unfavourable for both flowers, and as two bad seasons rarely follow one another we may hope that the gatherings which are already announced may be eminently successful.

And this brings me to notice what a very exceptional season it has been and how thoroughly it has frustrated the skill of even the best cultivators. We sometimes hear people foolishly talk as if the gardener were omnipotent; that no matter what the weather may be he is able to overcome its evil results, and that he can produce his flowers, fruits, and vegetables in the same perfection. The last season has completely shown the fallacy of this. The miserable failure of the fruit crop, especially of wall fruit, was not all; but even in houses, where glass and fire heat make gardeners so much more independent of weather, complaints were made of want of sunlight as affecting both the colour and the flavour of fruits. Then what about the crux of all cruxes, the Potato disease? Notwithstanding Mr. Worthington Smith's brilliant discovery of its resting spores and the proclamation of "salus" as a remedy for it, the disease has rarely been more virulent. Experiments conducted with great care have added nothing to our power of either curing or preventing the disease, and the commonplace method of procedure—planting early and lifting early, is about the only sheet anchor we have.

And now we look on hopefully. The prospect of a more severe winter seems to be vanishing, and it is much to be feared that there will be in some degree a repetition of last season—unseasonable earliness, and then sharp biting frosts to which fruit and flowers will alike succumb; still we may all find some oases in which to rest, something will give us enjoyment, and we must therefore be content with such things as we have.

I shall have as usual something to say on my own personal experience in my own little plot. In the meantime let me give a hearty greeting to all readers of the Journal; may they and their special favourites alike flourish.—D., *Doal*.

APPLES FOR ORCHARDS.

I WAS very pleased to see the name of our old friend Mr. Robson attached to an article on Apple culture in the Journal. I also agree with the remarks that he and "A NORTHERN GARDENER" made as to the Cellini Apple. In the remarks I made on the Apple election I said that it (the election) was of value for the amateur, but not to the same extent for the orchardist. I do not think there is an Apple enters the London market that has such a bad reputation as the Cellini. I endorse entirely the remarks of "A NORTHERN GARDENER," and think he has expressed in his letter the opinions of the consumers in the London markets. For myself I have used nearly all my trees as stocks for grafting other sorts. In considering what varieties should be grown by the orchardist there are two things to be thought of—first, Do you require immediate profit? or secondly, Do you wish to lay down a permanent orchard for the benefit of the next generation, and also to add to the value of the land, which in the case of a larger planter ought, for his own benefit, to belong to himself? In the former case I should recommend Lord Suffield, in the latter the Wellington (Dumelow's Seedling). I still think for the cottage gardener that the Cellini is one of the best, as it will make good wood and bear soon after planting; but I certainly should advise the orchardist to avoid it.

I am not quite certain as to the definition of the word "orchard" in all parts of England; with us in Kent we require a permanent pasture after a few years. In many parts I have seen Apple plantations with cultivated ground beneath, and therefore in the remarks I make about the sorts to be grown I am alluding to sorts fruited on pasture. I do not believe in planting on grass land. The young fibres of the roots do not receive the benefit they ought to do. For about seven or eight years the soil around a young standard tree

requires cultivation. In Kent we carry that to the highest state of perfection by planting in Hop grounds, and as there is nothing that is more highly cultivated than the Hop plant the young tree receives in a secondary degree much of the benefit intended for the Hop. One of the chief modes of cultivation for that plant is the aidjet. This is a five or seven-pronged scarifier, producing two good results—first, it destroys all weeds; and second, it gives a good "crumb," and therefore prevents the drought reaching the roots. After a few years the Hops are grubbed, and Grass seeds sown. The great value of an orchard on grass land as compared to a cultivated one is the saving in labour. In the one case by feeding sheep you reap a double benefit in fattening the sheep and improving the land (of course you must make an allowance for the cost of artificial food); in the other method of orcharding there is the cost of cultivating throughout the whole year, and the value of the produce in under fruit does not repay the deterioration in value that the upper fruit suffers in size and colour from that cause.

I have not yet proved Lord Suffield on large trees; mine are about seven years old, but I should think they would not hang in a wind, and therefore there would be a great loss if not gathered very early. The Beauty of Kent makes a tree faster than any other I know of, and bears well. The Lodington Seedling requires grafting on a free-growing stock, such as the Goff, and will then bear every year. The Minchall Crab is a very free bearer, and usually sells well. One of the most useful Apples for the orchardist is the French Royal (Pomme Royale), as it is a favourite with the consumers in the London markets. Warner's King and Tower of Glamis are also of great value on account of their size and handsome appearance. The Manks Codlin is a free bearer, but does not always command a good price. The Graham, when the tree has attained maturity, bears enormous crops, which find a ready sale in the spring. I have not yet sufficiently proved Cox's Pomona, but quite believe all that has been said in its favour. The Northern Greening, where the soil is suitable, is a free bearer and good for kitchen use. In some parts it grows very blotchy, this year especially so. But I think of all Apples the Wellington is the most profitable when you have a crop; but of course it is not so certain a bearer as Lord Suffield. There are many other kinds I could name, but I think a selection from those I have mentioned would answer for a small orchard of kitchen Apples.

In the dessert list for orchard planting I should prefer the King of the Pippins as producing the greatest money value in a succession of years at an early stage. When in full bearing the Blenheim and Golden Knob would probably pay better, but they would require fourteen or fifteen years before fruiting. Cox's Orange Pippin, of course, everyone would plant. I cannot say at present whether the trees, when they have attained their growth, will be constant bearers, but I am pleased with the appearance of them in their growing state. The yellow Ingestre (called in Kent the Summer Golden Pippin) is also a good bearer. I do not think there is any dessert Apple that fruits more freely than the Starmer Pippin; but unfortunately its merits are not known in the London markets. I have seen it in Covent Garden Market in September. It is not sufficiently attractive in appearance; but in April and May I think it only ranks second to Cox's Orange Pippin and the Ribston. I have a tree that has borne fruit every year for many years, but until I discovered the name some few years it was discarded as being of no value. I think the few sorts I have named, with the addition of Court-Panda-Plat, would be sufficient at first; but I shall be pleased to add a few more if required.—LEWIS A. KILLICK, *Langley*.

ARBUTUS UNEDO IN YORKSHIRE.

AT a distance of four miles from the east coast and at an elevation of 500 feet this very handsome evergreen sub-tree or tree-like shrub is perfectly hardy, but it flowers so late as to have them destroyed, which may, however, be due to the imperfect ripening of the wood quite as much as to the late flowering and cold. At an elevation of about 200 feet above the sea and distant about a mile and a half it fruits very freely and regularly, having shelter from north winds by plantations at a short distance, it having a southern exposure.

Beautiful as are the berries of *A. Unedo* at the dull season they are surpassed by Croome's Scarlet (*Arbutus Unedo* Croomei) and the Scarlet (*A. Unedo* ruber). Excepting near the coast, and there even in high and exposed situations, positions in

front of buildings with a south exposure are necessary for the fruiting of these very desirable evergreens. *A. Andrachne* is very handsome; it has bright orange berries in clusters, which are very ornamental, the tree being remarkable for casting its bark annually, leaving a smooth red trunk. Birds of the thrush tribe have a particular relish for the fruit, which they devour greedily.

I may mention that *Cotoneaster Simmonsii* is loaded with its orange-red berries; the erect form of the bushes and bright berries have a fine effect as seen among the dark monotonous forms of evergreens which usually preponderate in pleasure grounds.—G. ABBEY.

NOTES ON OUR ROSE DOINGS.

BEING at this present time in the south of France I am very interested in getting the home news of the floral and horticultural world in the *Journal of Horticulture*, which is kindly sent me each week from the office; but the very distance has prevented me hitherto from making a few remarks with regard to the letters on Rose shows, Rose judging, National Rose Society, &c. It was a great deprivation to me this year not being well enough to attend the different Rose tournaments, and especially not to be able to join with so many of my old friends in the re-formation of the National Rose Society. I was much interested consequently in the report of the annual meeting held on December 6th, which appeared in the *Journal* of the 13th December, and owing to the remarks of "A. C.," and also of Mr. G. Whitfield of Thirsk, venture to send you a few comments.

First, I think it would be an exceedingly good thing for the Committee or Council of the National Rose Society to draw out some rules for judging, though the practical difficulty in my mind, from what little experience I have had, is not so much as to the rules as to get judges capable of understanding or acting by them when drawn out. At the larger Rose shows where experienced and well-qualified judges are appointed there are seldom many mistakes made. Everyone as a rule is inclined to think favourably of his own stand, and very often thinks his own pets must be better than those placed before him. The general public, too, are not always able to judge of the relative value of large stands of Roses, which were under the eye of the judges perhaps at 10 o'clock, and seen by them between 1 and 2, after three or four hours in a hot tent. Any one who has had experience in judging large collections of seventy-two or forty-eight trebles will know that very often when coming back two or three hours afterwards to scan the awards there seems to be already a difference in the merits of the stands. A judge must not only know the comparative merits of Roses and the points of excellence, but he must be able to make up his mind and give his judgment tolerably quickly. I have known many men who were fond of Roses, and in a general way fair judges, who in difficult cases broke down simply from not liking to decide that A's collection was better than B's, perhaps because they knew by reputation that B oftener carried off the palm. As a general rule, where there are many collections it is easy, to begin with, to cast out (if there are only three or four prizes to be adjudicated) all those that have no chance; then, after taking another cursory view, it is better to select the most likely stands and go through each Rose point by point by giving marks. Usually the larger collections of seventy-two and forty-eight, &c., instead of being more difficult to judge are easier, especially if there are three judges and each judge takes it in turn in each stand (subject to the correction of the others) to give three points for the best, two for the next, cutting out all inferior Roses with no mark at all, and giving one for any Rose not bad enough to cut out, but yet deficient in some of the more standard points of merit, then, in cases of an extra good Rose, give four points. A mere addition sum will in the end generally determine the merit of these larger stands; but where, after the addition is made, two or three stands run very near it is better to pick the stands out, put them close to each other on the stages, or better still (if in a tent pitched on grass) on the grass, and take a general survey from some little distance if possible of the selected stands, and then see if the general view corresponds with the marks given. I know what I am saying now is the mere A B C to many experienced judges, but it is not for them alone I write. I find at many country and local shows gentlemen's and noblemen's gardeners are told off to go through all the cut flowers or all the classes of plants, and are selected haphazard, because the committee perhaps of the flower show

think that because they are gardeners at a great garden they must be good judges. Where this is done I have almost invariably found the judgments to be doubtful, especially as in these smaller shows the judges have to deal with twenty-fours, and twelves, and sixes, where, if there is any real competition, it is far more difficult to decide. I remember once at Tunbridge Wells, where I had to act as judge by myself, having twenty-six stands of twelve singles and twenty-two or twenty-three of twenty-four singles, where in each case at least nine or ten stands had to be gone through carefully.

I cannot quite agree with Mr. T. Moore's standard for judging new plants; nor, again, can one in judging take into consideration the merit of the Rose tree itself. It is very well to select for growing for exhibition purposes those "that have the merit of richness in colour, delicacy, form, size, associated with vigorous habit and free-blooming qualities;" but though judges may from their own personal knowledge and observation of the quality of the Rose know their habits of growth, &c., all they have to do at the time is to choose out of a certain number of stands or collections of Roses those which contain the greatest number of good blooms. There is also something to be said for variety in stands. For instance, I do not like to see too many reds or too many pinks, or too many of any one colour. Many exhibitors, again, will spoil a stand by having perhaps a hobby for Teas or Noisettes, by putting inferior Roses of those kinds in order, as they think, to vary the stands. I am afraid it will be difficult to get any committee or council to agree definitely as to the relative value of form, colour, size, symmetry, freshness, foliage, &c. In my own opinion I venture to say the first requisite is not only form and shape of the flower, but smoothness and form of the petal, and a general symmetry in the manner of opening, either in the reflexing of petals, as in some Roses, or in the high centre and cup-shaped forms of others. All roughness, quartering, uneven colouring, and coarseness, however large or fine the bloom might be otherwise, would be sufficient to deteriorate its value as an exhibition Rose. I am inclined, again, to give a point in favour of a good bloom (even if small) of one that is difficult to exhibit fine blooms of, as Madame Furtado or Mlle. Bonnaire, Marquise de Mortemart, &c. Then, again, coarse Roses such as Paul Neyron, or Baronne Prevost, or Reine d'Angleterre, &c., greatly detract from a stand. With some judges good moss and proper setting-up, heads of Tea Roses well wired to bits of stick, &c., have great weight. I certainly like to see stands well set up, the larger flowers in the background, the more delicate or decided colours separating the reds and pinks, and so on, but too much stress must not be laid upon this; and I am even heretic enough to wish to see nothing but plain, painted boards, not necessarily dull green, but some colour which should show-off the green of the foliage and the whole merit of the truss (as cut from the plant), anything the exhibitor likes to remove being removed, but nothing added. It is not wise, again, to put in Roses such as Jean Chérpin, or Souvenir de Dr. Jamain, or Madame Chirard, or any of these classes of small dark Roses, to make a variety in the stand, any more than it would be to put in bad blooms of Niphetos, or Safrano, or La Boule d'Or, &c., merely because they are Teas. However, I am digressing from Rose judging to Rose exhibiting, and feel I am somewhat bold in giving my opinion as to the merits of the points of a Rose in judging. I do not think it wise to try and draw too precise a line, but am inclined to put form and symmetry 1st; 2nd, smoothness of petal; 3rd, substance of petal; 4th, shape of petal; 5th, size; 6th, colour, especially freshness of colour with true gradations of tints; 7th, foliage; 8th, vigour of growth. Then, again, in a stand of say thirty-six or forty-eight, variety, within due limits, ought to have its merits; but, take it as a whole, "A. C." puts it very well when he says "Whoever has fewest inferior flowers wins," and no variety, produced by Teas, or Noisettes, or other means, will compensate for deficiency in good blooms.

I am glad to see Mr. Whitfield's remarks about the Rose elections. I have taken part in them and been interested in them from the first, and I must say on the whole the result of the election is far superior to any lists usually given by Rose-growers whose advice may be asked. Apparently his soil suits the Briar, and is, most probably, strong with a moist subsoil. I certainly agree with him that both Maréchal Niel and Marie Baumann are well worth growing in the north. I hail Marie Baumann's position in the Rose election list, as I have always thought a perfect bloom of this the most beautiful Rose that can be shown, not excepting even Maréchal Niel; and I cannot, again, understand why Mr. Radclyffe should

condemn Louis Van Houtte as a bad grower and recommend Pierre Notting, or why he should recommend such Roses as Vicomtesse de Vesins, Maxime de la Rocheterie, William Griffiths, Pierre Seletski, Souvenir de la Reine d'Angleterre, Sir Joseph Paxton, &c. If Baronne de Maynard is a Bourbon so must Boule de Neige be; but to my mind they are neither of them Bourbons but Hybrid Perpetuals, with a tendency to the Noisette rather than the Bourbon. Why, again, cut out François Michelon and Emilie Hausburg? I agree with him that Gloire de Dijon is too low, and so perhaps is Maurice Bernardin, but Pierre Notting is as high as an uncertain Rose which generally burns in the sun deserves to be; and Madame C. Joigneaux, though a good garden Rose, will never see the exhibition stands again very often. Mr. Radclyffe may be a good judge of what grows best in his own garden, or what is most vigorous in nurserymen's gardens, but quality is better than quantity, and the opinion of forty-eight rosarians is not to be lightly cast aside. With me, contrary to Mr. Whitfield's experience, the Briar is no good with Marie Baumann or Maréchal Niel, but then my soil is light with sand below, and I shall never grow another standard as long as I grow Roses; and I hope in time that the rage for long sticks with mop heads, grown contrary to all the natural laws of Rose-growing, may die out. Use the seedling Briar or dwarf Briar as stocks where the soil suits; but, except under very particular circumstances, I hope the Briar standards may come to an end. I send these hurried notes as helping to ventilate the subject. If my old friend Canon Hole is Chairman of the Committee to lay down laws for judging Roses I venture to say there will be a good code of rules drawn-up to guide Rose judges.—C. P. P.

ZINC LABELS.

I DO not think that zinc labels because they are zinc do any harm whatever to either Roses or fruit trees. If harm results I believe it is by abrasion, the labels either being too loose, so that they are blown about by the wind, causing friction when the bark is tender; or too tight, and the sap is arrested.

Some years ago I had some fruit trees and Roses from a Belgian nursery, with their numbers stamped on very thin sheet lead, which was in long strips about half an inch wide and coiled round a stem or branch. As the wood increased in size the labels uncoiled to the same extent. The same stems or branches have worn the same labels for ten years, and not in one instance has injury resulted to either fruit tree or Rose. On inquiry at the nursery whence the trees were obtained I was informed that the plan had been adopted for a quarter of a century, and hundreds of thousands of trees had been subjected to this system of labelling and no injury had been known to result from the practice. I have employed zinc labels in the same manner and with the same satisfactory results.

Whether the action of zinc and copper as employed by Mr. Brown (see page 8) is deleterious to trees I am unable to say, but zinc alone when carefully secured round the branches I have found quite innocuous.—AMATEUR.

MARKET APPLES.

I AM sure "A NORTHERN GARDENER" (p. 496) will excuse me if I point out an error into which he has fallen respecting the Duchess of Oldenburgh, or, as we call it, the Russian Apple. He says that my father told him it was a good Apple to travel, and could "hide its bruises" well. There must be some mistake in this, as my father—indeed, any grower of this variety—would know well that such is not the case; on the contrary, although a fine summer Apple of excellent quality for culinary purposes and a very good bearer, I should say it is the most tender-skinned Apple grown. So much is this the case that on wet days we never pull Russians, or they would be ruined completely. Even with the most careful gathering it shows every finger mark. It has, however, this good quality—that if stored away in the hampers for four or five days the marks will almost entirely disappear; you can then take them to market, where they will invariably make more money than any other Apple at that season of the year. The people who find Russian Apple a bad sort are those who gather their fruit, put them down on a floor or elsewhere, again put them into hampers, and take them to market. When treated in such a manner it is by no means a good selling Apple.

I cannot say much about the Cellini, for although we sell hundreds of it as young trees, it is not a variety which we

grow in the orchards. I am surprised that "A NORTHERN GARDENER" does not mention Northern Greening, which is one of the best market Apples we possess; a fair size, good bearer, and second only to Normanton Wonder as a late cooking Apple, in use from December to April. Barton Free Bearer is also a market Apple which is worthy of mention; although of perhaps second quality as regards flavour, it is a variety which always bears. We have fruit-gatherers who have worked with us for over twenty years, and who never remember "Bartons," as they call them, failing. Of course they bear more some years than they do others, at the same time they are never a total failure.

I quite agree with your correspondent's remarks as to Beauty of Kent, Normanton Wonder, Warner's King, &c., but, with the exception of Normanton Wonder, how can they be compared as market Apples with our old friend Keswick Codlin? I do not speak of their respective quality in an eating or cooking sense, but of their value per acre as market Apples.—ALFRED H. PEARSON, *Chilwell, Notts.*

VEGETABLE CULTURE.

CHAP. II.—THE POTATO.

PREPARING THE GROUND.—The Potato is one of the most accommodating of vegetables. Of course in a soil entirely suitable to it is the most productive, but it will produce a fair crop in ground that would hardly bring any other vegetable crop to maturity. A heavy wet soil is the most unfavourable for Potato culture, for in such soil they not only fail to attain a good size, but as a rule they partake of the soapy character of the ground, and disease is always most prevalent in wet soils. A too dry soil should also be avoided, at least if it is at all poor. We always obtain much the finest crops from a well-drained friable soil, which does not hold superfluous water nor become quickly parched in dry weather. Either of these extremes is most injurious to the crop. Wet lodging about the roots soon generates disease, and excessive dryness causes the tubers to ripen small and prematurely. Careful selection of soil and situation has more influence in preventing or modifying disease than any remedy which can be applied during their growth. I am aware that some who imagine they can stop the Potato disease will not agree with me in this; but I do not write for argument, on the contrary, I merely state convictions gathered from extensive and successful practice. The most plausible theory will not stand against this.

It is always advantageous to trench-up the vegetable quarters to the depth of 2 feet or 30 inches every four or five years. Where the subsoil is the least inclined to be clay some of this will be brought up to the surface in trenching. Few small seeds can be profitably grown in this for the first year until it has been pulverised or opened-up into free working order. The Potato is the best of all crops to plant to accomplish this. It may also be planted after any kind of vegetable. It may further be planted annually for many years on the same piece of ground. Most of our south and other borders round the walls are planted with Potatoes every spring, and when the ground is cleared of them other vegetables, such as Turnips, Spinach, Lettuce, Endive, &c., for use in winter, take their place. In the large kitchen-garden quarters they are hardly ever grown in the same place two years running; but in small gardens, where it would be difficult changing their position annually, the crop will suffer little by being grown on the same piece of ground for many years together. Ground on which Potatoes are to be planted which has previously contained other crops should have manure spread over the surface and the seed put in as the ground is turned over. I may remark here that heavy cow manure is not the best for Potatoes, unless the ground or soil is exceptionally light. Decayed leaves mixed with light straw and horse dung in a decayed state grow fine clean tubers. In heavy soil wood or house ashes mixed with the manure is beneficial.

VARIETIES.—As may be seen from the now popular Potato shows there are hundreds of varieties of the Potato in cultivation in this country; but, unless where they are grown for the mere sake of variety, a few really good sorts will give as much satisfaction as hundreds. At one time we grew many more sorts than we do now; but we have reduced them to the following, which possess every good quality desired in Potatoes:—

Early Varieties.—Myatt's Prolific Ashleaf (Rivers's Royal Ashleaf), Mona's Pride, Early Fortyfold, and Fenn's Early Market.

Second Earlies.—Gloucestershire Kidney, Lapstone, and Dal-mahoy.

Late Sorts.—York Regent, Sutton's Red-skinned Flourball, Paterson's Victoria, and King of the Flukes.

Most of the American varieties are very prolific, but as a rule they are deficient in flavour. By this I mean they seldom cook "mealy," but at the same time they are not by any means unfit for food. In small gardens where the most must be taken from a small piece of ground, and in poor men's gardens where quantity is as desirable as quality, the American sorts should be cultivated exclusively. Snowflake, Bresee's King of the Earlies, Early Rose, Eureka, and Late Rose are the best of them. They have all a wonderful disease-resisting character.

PREPARING THE SETS.—Various opinions are entertained respecting the best kind of sets for planting. Some prefer planting smallish Potatoes whole, others believe in cutting them up. Good crops may be secured from both. When seed is scarce each tuber may be cut up into as many sets as it has good eyes. A large Potato may often be cut into five or six sets. Where the seed is plentiful it is best to leave two eyes to each set. Small roots about the size of pigeons' eggs may be planted whole. Kidney varieties do not bear cutting-up so well as round sorts.

When Potatoes are stored in heaps in autumn the earliest sorts soon begin sprouting, and if they are not watched the shoots will become very long. This weakens the tuber and injures it very much for planting. Potatoes for planting should be turned over every three weeks during the time they are stored to prevent the long growths appearing. About a month before they are wanted for planting spread them out thinly in a cool dry place where frost cannot reach them. They will grow there, but the shoots made will be short, strong, and hardy—just the sort which will not perish when planted in the ground. In cutting the tubers do not injure one of these growths, as they are of considerable advantage. Tubers so prepared grow much faster than dormant sets.

PLANTING.—In favourable localities Potatoes may be planted from the beginning of February until the end of March. Where late spring frosts are prevalent no tubers should be planted until the middle of March, and from then on to the middle of April. Early planting is best when it can be done with safety, as it gives the tubers a better chance of becoming matured before the autumn rains set in than when planted late. Early varieties, too, have an advantage over late sorts in this respect; our early kidneys planted in February and lifted in July always escape the disease more than later sorts. The ground should not be saturated with wet when planting is done. Some dig the ground all over first and then insert the sets with a dibble; but by this plan I fancy the seed is too much confined at first. An opening should be taken out at one end of a piece of ground, and as it is turned over form the rows as each distance is reached. The distance between the rows and sets should be regulated by the vigour of the variety. Strong-growing kinds require more space than those which produce short haulms. The strongest-growing sorts should be planted 30 inches between the rows and 12 inches between the sets. Weaker kinds, such as Rivers's Royal Ashleaf Kidney and King of the Earlies, do very well with 20 inches between the rows and 6 or 8 inches between the sets. From 4 to 6 inches is a good depth to cover the sets under the surface.

GENERAL CULTURE.—When planting is finished the general requirements of the Potato throughout the growing season are very few. Do not disturb the surface of the ground until the growths are well up and the rows can be distinctly seen, then take a Dutch hoe and break the surface thoroughly. This will be all they will require until the stems are 6 or 8 inches high. Break the surface again between the rows with the Dutch hoe. When this has been done, a draw hoe should be taken and a good quantity of the soil drawn to the stems with it. This earthing-up supports the young stems, and when the tubers swell it generally prevents them from being exposed on the surface. In exposed situations a little earth may be drawn to the stems as soon as they are a few inches above the ground, and the operation may be completed when they have advanced a little in growth. After earthing-up, the ground may be run through again with the Dutch hoe to break the surface if it is crusty and destroy the weeds. When the stems have met in the rows, however, it is only necessary to pull out with the hand large weeds before they seed.

Lifting and Storing the Crop.—Perhaps there are more diversity of opinions as to when Potatoes should be taken out of the ground than on any other matter connected with their

cultivation. Some recommend lifting them as soon as the haulms show signs of disease, others after the stems have wholly died down. Both may be correct under certain circumstances; but all matters considered, when the tubers have to be kept for a considerable time for seed or other purposes, it is best to allow them to remain in the ground until the haulms have turned yellow and are drooping with maturity; then the roots both eat well and keep well. Like all other operations connected with their culture, they should only be lifted from the ground when the soil is dry and will not adhere to them; this is important to their subsequent keeping. When lifted for immediate use this is of no importance. As soon as they are lifted they should be placed in an open shed or some other place where there will be no danger of rain falling on them. As each sort is taken under cover spread them out thinly and let them remain for a few days until they have become perfectly dry, then go over them and pick out every one showing the least sign of disease. The very smallest may be taken out at the same time. The good tubers then left should again be spread out for a few days to dry them thoroughly before storing.

The best place for storing them in is a dark shed or cellar, but the former is the best. The temperature of the place should not fall below 35° or rise above 45°. They may be laid together in heaps 2 or 3 feet deep, but where there is plenty of space they may be spread thinner. After storing they should be turned over once every three weeks or a month, and any showing indication of disease be removed. Our Potato shed has no windows, but a few holes in the walls for ventilation. These are opened during fine days to admit fresh air and let out any moisture that may have collected in the atmosphere. Where there are windows in the shed they should have shutters to exclude the light, and they may be opened occasionally to sweeten the air inside. We stored our Potatoes in ridges in the open air at one time and covered them with straw and earth, but this we have discontinued, as we find the shed much more convenient.

INSECTS AND DISEASES.—Excepting the famous Colorado beetle, which we have only seen on paper, there are few or no insects which do serious harm to the Potato stems or leaves. The curl is often injurious. When affected by this the stems and leaves curl and shrivel-up, and growth is stopped both at top and bottom. Very dry weather sometimes causes it, and an over-abundance of manure seems to promote it. Excessively rich or extremely poor soil also appears to favour the spread of scab or ulcers, which appear on the surface of the tubers. This sometimes disfigures the tubers very much, but when peeled the centre is quite good for food. The Potato disease, which annually proves so disastrous, is too well known to require any explanation. As previously stated, every means tried hitherto to prevent it has failed. Avoid planting in heavy wet soil; plant early and lift early, and changing the seed frequently, are a few of the best practical means that can be adopted to modify it.—A KITCHEN GARDENER.

MILDEW ON ROSES.

"AN OLD ROSE-GROWER" states that he is open to correction in recommending that water should not be given to Roses, especially after a hot day, as it induces mildew. So far from correcting him I strongly endorse his statement. Mildew with me has always commenced in a hot south border with the most vigorous Rose, John Hopper, whence it gradually spread. In 1875 I watered freely the Roses in the border just when they appeared to want it most—viz., after a hot day. They suffered immediately from mildew, and did not recover that season. The more I watered the worse they became. In 1876 I mulched heavily with manure and gave no water; no mildew whatever appeared. This year, having no manure to spare, I watered moderately till mildew appeared; I then withheld, until the plants recovered entirely from the pest and bloomed well in the autumn.

I am far from saying that this is the only cause of mildew, which I believe results immediately from a checked root-action acting on a vigorous condition of foliage. Heat and dryness of the root will induce it; but I am certain that cold water applied to warm roots, however thirsty they may be, is the surest way to aggravate the evil, which becomes worse in proportion as the foliage is luxuriant. In case of drought, or rather to anticipate the drought, which is sure more or less to come, mulch heavily with manure, but never water. If the unsightliness is objected to cover with cocoa-nut fibre or a

sprinkling of earth, but do not dig it in. You will then, I think, escape mildew, at least I have done so.—A. JOHNSON, M.A., F.L.S.

ORCHIDS IN JANUARY.

AT this dull season of the year, when the more common flowering plants are few, and the Chrysanthemum, the queen of winter flowers, is fast fading, the Orchid house affords a "feast of beauty." Plants that are now in flower or showing flower in many collections are the following:—*Angraecum eburneum* and its varieties are now expanding their large ivory-white flowers, also *A. sesquipedale*, which I think are the two best species to represent this genus. They should have a fair supply of water at the roots now they are in flower; in fact, they should have had a good supply from the time the spikes were visible. *Ansellia africana* is now making a grand display; it flowers from the extreme point of the pseudobulb, showing its yellow flowers with chocolate markings well above the foliage. This should be grown in company with the *Vandas* and *Aërides*. It delights in peat and sphagnum with a little fibry loam. Plenty of water should be given at the roots when growing. After it has completed its growth it will be greatly benefited by removing it to the Cattleya house for a time and watering it very sparingly to prevent its starting into growth prematurely. *Cypripedium insigne* and *insigne* *Maulei* are now in one mass of bloom; they have been in flower with us for about six weeks, and continue in good condition for some little time. *C. barbatum*, *pardinum*, *venustum*, *Roezli*, *Sedeni*, *Harrisianum*, *Dominianum*, and *longifolium* are scarcely ever out of flower. The last-named species are kept regularly supplied with water at all seasons.

Cymbidium eburneum has been in flower for two or three weeks. This when well grown is really one of the best species in cultivation. *C. sinense* and *C. pendulum* are also in bloom. The two latter are thought but little of at the present time, owing, no doubt, to their being so shy in flowering. *Dendrobiums* of the noble section will now be fast coming into flower. Where these are grown in quantity and with a little skilful management a grand display may be kept up for a considerable time. Our plants of *D. nobile*, that finished their growth early and were subjected to a good roasting on shelves well exposed to the sun's rays during August and September, are now fast opening their flowers; the second batch should be kept comparatively dry and cool. By introducing one or two plants at intervals into the East India house a good succession of flowers may be kept up for a long time. If grown in baskets I find it a good plan to give them a pretty good soaking with water, and to damp the stems once or twice a-day till the flowers are at the point of opening; but plants grown either in baskets or pots should not be allowed to be saturated with moisture, which would cause them to start into growth prematurely. Following on in succession are *D. Pierardi*, *heterocarpum*, *primulinum*, *crassinode*, *Wardianum*, *Devonianum*, *japonicum*, &c.

Dendrochilum glumaceum should now have special attention. This should be brought out of the Cattleya house, potted if necessary, and placed near the glass in the East India house, as it will now be throwing up its pseudobulbs in quantity. When it has fairly started into growth it should receive a liberal supply of water, as it makes roots and flowers with the young bulbs. I find it thrives admirably if potted in fibry peat, chopped sphagnum, and good fibry loam, with an admixture of broken charcoal or crocks to keep the soil open. *Laelia autumnalis* has also been in flower for some considerable time, and must be allowed to rank amongst one of the best and most useful species of that lovely genus. The flowers are extremely useful for bouquet-making, also for mixing with other flowers for filling vases for dinner-table decoration. *L. anceps* will be in flower in the course of two or three weeks, also *L. superbiens* with its flower-spikes from 4 to 5 feet long. The last-named species is scarcely worth growing unless anyone is in possession of a good variety.

Lyostea Skinneri has been very attractive for six or eight weeks past, and should find a place in every collection; even the poorest varieties are really beautiful. *L. linguella* will very shortly be in flower, and should receive a liberal supply of water, as it makes roots and sends up its flower stems at the same time. I have seen this species produce thirteen and fourteen flowers from strong pseudobulbs. The flowers are shining and of an ivory-white colour.

Where even small collections of *Maedevallias* are grown there is scarcely a time of the year but what some will be in

flower. *M. Veitohiana* and *M. Harryana* are perhaps the best two species of the genus, though *M. tovarensis* is a great favourite, showing its flowers, which are as white as snow, well above the dark green foliage. The last-named species has only found its way into a few collections, doubtless owing to the great price it realises, there being only a small stock at present in the country. It was first discovered in Tovar, British Columbia, hence its name. *M. polysticta* and *M. melanopus* are two little gems, wonderfully free-flowering, beautifully scented, and lasting a long time in flower. *M. ionocharis*, *Davisi*, *amabilis ignea*, *Peristeria*, *nycterina*, *psitticina*, and *Lindeni* are all well worth growing. All the species are very easily cultivated. The main points of attention in growing *Maedevallias* are:—First, to keep them growing in a sweet mixture of fibry peat and sphagnum, with some fine broken charcoal mixed with it; secondly, to keep them cool; thirdly, to keep them well supplied with water when growing—in fact, they should never be allowed to become dry.

Now is a good time for *Odontoglossums*, as there are many good species in flower. For example—*O. Alexandrae* in variety, *bictonense*, *cariniferum*, *cirrhosum*, *clariceps*, *cordatum*, *crocidipterum*, *constrictum*, *cristatum*, *Ehrenbergii*, *epidendroides*, *gloriosum*, *grande*, *Hallii*, *hastilabium*, *Inslayi*, *Lindleyanum*, *luteo-purpureum*, *lavæ*, *Pescatorei*, *pulchellum*, *Rossii*, *triumphans*, and *Uro-Skinneri*.

*Oncidium*s in flower are *O. Barkeri*, *bracteatum*, *cheiroporum*, *crispum* in varieties, *cuscutatum*, *grandiflorum*, *excavatum*, *flexuosum*, *luridum*, *ornithorhynchum*, *papilio*, *pubes*, *sarcodes*, *sphacelatum*, *serratum*, *suave*, *Schlumi*, *reflexum*, and *triquetrum*. The last-named species is never out of flower, and is greatly used for making button-hole bouquets. *Phajus grandifolius* is now sending up its flower spikes in quantity, the earliest of which will shortly be in flower. This is a very useful species for decorative purposes.

We next come to that most lovely of all Orchids, *Phalænopsis Schilleriana*, commonly termed the queen of Orchids, and it is well worthy of the name. Strong healthy plants of *P. Schilleriana* are now throwing up their long branched spikes of flowers, and will come in at a good time for cutting. *P. amabilis* and *P. grandiflora* are also showing signs for a good supply of flowers. Last on the list, but not the least, comes our old friend *Zygopetalum Mackayi*, which has been in beauty for some five or six weeks past. I know of no other Orchid that is more accommodating than this, for I find it grows equally well either in the East India house, Cattleya house, or *Odontoglossum* house.—W. G.

DECEMBER FLOWERS—CAMELLIAS, AZALEAS, AND ROSES.

I AM very glad that I went to Veitch's in December, since I have afforded pleasure to a cultivator of Mr. David Thomson's high standing. Mr. Thomson has shown his appreciation in a very practical manner, by not only noticing a weak point in December decorations, but by pointing out a remedy.

When I alluded to the absence of flowers of Camellias and Azaleas during the depth of winter I had in my mind the fact that I was referring to a period before which those valuable flowers are usually in beauty. At Veitch's they were not "in," and in nine-tenths of private gardens those plants are not seen in good condition until the "turn of the year."

In the case of Camellias I have fully proved the certainty of their flowering in December by habitually starting them into growth early in the spring, and I have found the value of such a practice. I have also, but to a more limited extent, found that Azaleas may also be had in beauty at Christmas. I have had the valuable old *A. amena* "in" at that time, also the *A. indica* varieties *Gloire de Belgique* and *A. Borsig*, and I now thank Mr. Thomson for naming others that he has found amenable for Christmas decoration.

I saw some charming Roses in Covent Garden at Christmas. Will Mr. Thomson or others who may have had experience in flowering Roses at that time oblige by describing their practice, naming also the best varieties to commence with? I suspect they are as easily produced as Camellias and Azaleas, and where is the flower-loving family who would not welcome Roses at Christmas?—A COUNTRYMAN.

ADIANTUM PALMATUM.

PROBABLY no Fern more quickly established its popularity than the beautiful and now familiar *Adiantum farleyense*.

That, however, is a stove Fern, and is consequently beyond the conveniences of many lovers of these elegant plants. The Maidenhair now figured bears a general resemblance to the fine species alluded to, and has already received the popular

appellation of the "greenhouse farleyense." *A. palmatum* is, however, very distinct from *A. farleyense*—distinct by its dwarfer growth, more finely divided pinnæ, and its different tint of green. It is a Fern of great elegance, and will doubt-

FIG. 6.—ADIANTUM PALMATUM

less thrive in an intermediate house or close warm greenhouse, and will thus be within the means of many cultivators who do not possess highly heated structures. It was, says Mr. B. S. Williams, to whom we are indebted for its introduction, discovered by M. Roezl in Peru at an altitude of 10,000 to 11,000 feet. In "The Gardeners' Year Book" recently published it is described as "a handsome species, allied to *A. speciosum*. Fronds scrambling, elongate, narrowed to apex, laxly tripinnate; pinnules stalked, varying from obovate-cuneate to semi-orbicular, 1-1½ inch broad, palmately cleft half way

down; sori oblong, situate on the tips of the segments; stipes and rachis smooth, dark brown." That description, with the accompanying illustration, will enable a correct idea being formed of the appearance of a Maidenhair which is likely to become popular.

LÆLIA FURFURACEA.

LÆLIA AUTUMNALIS is now finely in flower in some of the London nurseries, and it may therefore be opportune to notice

L. furfuracea—a rare and nearly allied kind—first because of its intrinsic beauty, and then to indicate how these accepted species differ. There is no ground on which to found a specific distinction, they are really forms of one type. It is just an example of those frequently occurring cases where a difference of slight botanical consequence is of great horticultural importance. Here we have two forms of equal beauty, one of which, *L. furfuracea*, is cultivated with difficulty, wanting the freer growth and to a great extent the exquisite perfume of

L. autumnalis, which of course is the most valuable for cultivation.

Before us we have a flower of *L. autumnalis*, which, compared with the *L. furfuracea*, has shorter sepals, and the petals are less rhomboidal and not undulated. They are scarcely at all oblique, and may be described as ovate-acute, thus having less width above the middle; the sinuses which form the labellum into three lobes are also deeper. This has several flowers on a stem, in contrast to which the stems of *L. fur-*

Fig 6.—*LÆLIA FURFURACEA*.

furfuracea appear always to be one-flowered; it has also narrower leaves. Comparative description without a suite of specimens is often misleading, we therefore recommend attention to the number of flowers on the stem. We suspect a range of varieties uniting the two by imperceptible gradations, wherein also are some having the several forms of each organ which compose the flower in different combination. This view is strengthened by the figure of *L. autumnalis* in the "Botanical Magazine" of 1840, which seems different from any we know of now. Both were figured in the same year with also *L. anceps*, an allied but distinct species. All were from the collection of the Duke of Bedford at Woburn Abbey, where they were received from Mexico. Lindley mentions the "black mealy glands" on the ovary as a distinguishing point of *L. furfuracea*,

but these we find also on *L. autumnalis*. The pseudobulbs of the latter are described as ovate, in contrast to the oblong-lanceolate form belonging to *L. furfuracea*. This cannot always obtain, for our plant has been carefully determined and the pseudobulbs are distinctly ovate. The continuity of nature is rarely better seen than among Orchids, and the definition of a species is clearly arbitrary. There is a plant in flower at Kew, received from M. Roelz; the lateral incurving lobes of the labellum are pure white and the middle lobe a deep magenta, as are also the sepals and petals, shading below to nearly white. The colour is of great purity, and the petals have a crystalline appearance we do not find in flowers of *L. autumnalis*. It may receive the same treatment as for this plant, and having in view a collection rather than selection, is well

worth attention and trouble. Though considered difficult of cultivation and shy of blooming, it has been grown luxuriantly, flowering well every year.

SHADING—KEEPING GRAPES.

HAVING referred on page 3 to the matter of shading Camellias it may perhaps be well to allude briefly to the subject of shading generally. The shading of plants, &c., under glass varies according to circumstances.

Shading is much more necessary in some places than others, and is required most of all in wet dull climates. For instance, I have been obliged to shade things more in a few years in Dumfriesshire than I did in all my former practice, and the reason is that here we have longer spells of moist sunless weather, frequently succeeded by a time of brilliant sun; and growths made by Pines, Melons, Camellias, and even Vines during the sunless time are so tender and immature that, if not shaded for a time, when overtaken with a time of brilliant sun they would simply be ruined. So much is this the case that I am preparing a tiffany shade for the Muscat vine, so difficult is it to preserve the foliage made in our dull climate when overtaken with sun. These same conditions necessitate very different practice as to supplies of water and temperatures compared to what has been my practice under brighter skies, hence it is obvious how ridiculous it is to prescribe the same practice for very different localities.

While speaking of Vines there is one circumstance that puzzles me much, and that is the keeping qualities of Grapes ripened under the circumstances of wet and cloud indicated above. We seldom ever lose a berry here (even at the most critical period of the fall of the leaf) from damping-off; certainly not one berry for ten that I have seen decay in the much more bracing clear air of Haddingtonshire, where Grapes were ripened under very much more sunshine. This is the more remarkable from the fact that the gardens here are situated in a valley surrounded with dense woods with a rainfall in November and December alone not unfrequently exceeding 20 inches. Last December gave us 10½ inches, and the total rainfall during the year 1877 was 67½ inches. The Vine borders are not covered, and scarcely ever a berry has to be cut out of a bunch of Grapes, and yet even ordinary precaution is not practised, because it is not found necessary. A correspondent on page 7 suggests that Muscat of Alexandria is not to be relied on after the end of the year. I have known it good in the middle of March, and if well ripened few Grapes keep so well.—D. THOMSON, *Drumlanrig Gardens*.

HOME-GROWN TUBEROSES.

I WAS not aware that home-grown Tuberoses were almost unknown in this country till I read some communications on the subject in the pages of a contemporary. Allow me now to inform your readers that Tuberoses can be grown as easily as an *Amaryllis* or *Eucharis*, and what is more, they can be grown so as to produce flower stems stronger than the imported bulbs and to flower at a time when those imported almost refuse to do so.

The imported bulbs are received in December or January, when they are at once potted singly in 6-inch pots and plunged where they can have the benefit of bottom heat to start them into growth. After they once start fairly they can be grown in a lower temperature and without bottom heat; and when all danger of frost is over, if they are not wanted to flower early, they can be placed in a deep cold pit and be merely protected from the worst of the weather till the flowers commence opening, when they will be improved by being taken into the greenhouse. Plants so treated will generally flower some time between July and October.

After flowering most people throw them away as useless. This is quite a mistake, as I will endeavour to prove. Mine are at once shifted into 7 or 8-inch pots without disturbing the ball, using a good rich compost consisting of turfy loam with a little decayed manure, a few half-inch bones, and a little charcoal. They are again placed in a warm house and soon commence throwing up shoots, one of which only is left to grow, and it soon forms a new bulb on the top of the old one, which will not fail in its turn to send up a good strong flower stem.

I have no doubt that the small shoots which are taken off would, if liberally grown, soon make good plants. I have already grown some of them this way, and was not aware

that it was an uncommon thing to do, but I have kept no notes concerning the time it takes, yet I am under the impression that some of them flower again during the following winter. I have several in flower at the present time. One stem a few days ago had seven fully expanded pipes at once, and although I cannot yet say that I have had them every week in the year, I do not consider it would be at all a difficult matter if a sufficient number were grown, for it appears to me that they throw up a flower stem whenever the bulb and roots get sufficiently strong, independent of the time of year.

The double variety called the American has been mostly grown, but the Italian one does equally as well under the same treatment, and I almost think I like the Italian one best.

They are never dried off, and this is probably the reason they come stronger than the imported bulbs.—W. TAYLOR.

NOTES AND GLEANINGS.

DURING the year 1877 Messrs. JAMES VEITCH & SONS of the Royal Exotic Nursery, Chelsea, were awarded at the various meetings of the Royal Horticultural Society thirty-eight certificates (thirty-four being first-class) for new plants, two first-class for new vegetables, and two second-class for new plants. They also received from the same Society in the same period two botanical certificates, one cultural certificate, and two botanical commendations. This is the largest number of certificates, we believe, that has ever been awarded by the Society in a single year to one firm. Messrs. J. Veitch & Sons also received from the Royal Botanic Society in the season of 1877 thirty-three certificates of merit for new plants, twenty-seven of which were botanical and six floricultural.

THE Committee of the HORTICULTURAL CLUB announce that they have been enabled to make arrangements, which they believe will greatly conduce to the comfort of the members and the well-being of the Club, as they have entered into an agreement with the well-known Temple Club, Arundel Street, Strand, which secures to their members the advantage of all the resources of that establishment. An inaugural dinner will take place at the new Club House on Tuesday, January 15th, at six o'clock.

IN addition to the GARDEN PILFERING mentioned last week we are informed that some Briars were recently stolen from one portion of the grounds of a suburban nurseryman, and actually sold to another branch of the same firm before even the robbery had been detected. This is about as flagrant an instance of roguish impudence as has ever come under our notice. It behoves nurserymen to be careful from whom they purchase, since the new "trade" appears to be in active operation. The theft of Briars alluded to last week occurred in Mr. Ware's not Mr. Hale's nursery.

"A GROWER OF FORTY VARIETIES" recommends the following as useful LATE-FLOWERING CHRYSANTHEMUMS:—Her Majesty, Mount Etna, Mrs. Halliburton, Oliver Cromwell, Grandiflorum (Japanese), and Lady Slade; and of Pompons, St. Justia, Florence, Mr. Astie, Aigle d'Or, and Dick Turpin. "J. P." also sends the following as useful varieties. Of large-flowering—Nonpareil, Lord Ranelagh, Yellow King, Pink Perfection, Princess Teck, Sir Stafford Carey, Virginal, a very late Anemone-flowering variety, probably the latest of all. Pompons—Aurea, Mdile. Marthé, Bob, and Calliope. Of Japanese Chromatella is the latest; while The Damio, Dr. Masters, James Salter, and Fair Maid of Guernsey have bloomed late this year.

LEICESTERSHIRE FLORA.—The natural history section of the Leicester Literary and Philosophical Society is engaged in verifying and bringing up to date the MS. of the Flora of Leicestershire, left by the Rev. W. H. Coleman of Ashby about twenty-five years ago. Any botanist in the outlying districts of the county will be rendering useful assistance by sending lists of plants observed to the President of the section at the Town Museum, Leicester.—(*Midland Naturalist*.)

FROM letters we have received respecting large ARAUCARIAS we gather that the finest tree in England is the splendid specimen at Dropmore, which exceeds 60 feet in height and is about fifty years old. There are also very fine examples at Messrs. Mitchell's nurseries at Piltown, also in the Great Berkhamstead nurseries of Messrs. Lane. Seed has been ripened and seedlings raised in those nurseries, also at Strathfieldsaye (the Duke of Wellington's), Warfield (Lord Ormawatha's), and at Bicton (Lady Rolfe's), where very fine trees may be seen. The trees are generally diocious, but at Bicton

and at Castle Martyr (Earl of Shannon's) both male and female catkins have been produced on the same trees. Seeds have been ripened in Scotland at Castle Wigg, Wigtonshire, but the finest tree in Scotland is, we think, at Keir (Sir W. Stirling Maxwell's); it exceeds 50 feet in height. The largest tree that we have heard of in Ireland is at Woodstock. It was planted by Col. Tighe fifty years ago, and exceeds 50 feet in height. There is also a very fine specimen in Mr. Boyd's garden at Ballymacool, Co. Donegal. The largest tree we have heard of in the Isle of Wight is in Miss Johnson's gardens at Willow Bank, St. John's, Ryde. We should be glad to hear the exact heights of those trees and of other noteworthy specimens.

— MESSRS. CARTER & Co. have issued a liberal schedule of prizes offered by them, to be competed for at the different meetings of the Royal Horticultural Society during the ensuing season:—£25 10s. is offered in six prizes for thirteen varieties of vegetables; £15 15s. in five prizes for three dishes of Peas; £4 in four prizes for the new Khiva Melon, also a similar amount for Cream Pine Melon; £10 in five prizes for groups of twelve flowering annuals; £3 3s. for Vick's Criterion Tomato, and £11 11s. for ten varieties of vegetables.

— WE have to record the DEATH OF MR. THOMAS MOFFATT, which event took place on the 4th inst. in his ninety-first year. He was gardener to the late Viscount Sydney at Froggnall for a period of twenty years, up to the time of his lordship's death. He then went to Clumber Gardens, where he served three Dukes of Newcastle—the father, the son, and grandson, and was much esteemed by all the members of their Graces' families, being a man of large and varied information, and eminent as a thoroughly practical gardener. He was the oldest Fellow of the Royal Horticultural Society, and was appointed by that Society to form one of a Committee of three to choose a site for the new garden about to be formed, when Chiswick was selected as the most eligible out of several estates inspected, and the recommendation of the Committee was adopted. He was a man of high principles, strict integrity, and faithful in his friendships.

— THE Lisbon correspondent of the *Daily News*, writing on the VINES OF MADEIRA, says:—"Late accounts from Madeira speak very discouragingly of the precarious condition of affairs in the island, and the gloomy look-out for the future. The Vines have suffered terribly, and almost promise to disappear before the ravages of the dreaded *Phylloxera vastatrix*. As all the world knows, the Vines of Madeira constitute its principal sources of wealth, and they were beginning to recover from the disease, many new vineyards having been planted. The cultivation of the Sugar Cane has been tried as a substitute for the Vine, but it does not appear to offer the advantages hoped for, on account of the competition of the sugars of South America, the West Indies, and other places."

— WE have received the first number of a new monthly publication entitled "THE MIDLAND NATURALIST: the Journal of the Natural History, Philosophical, and Archaeological Societies and Field Clubs of the Midland Counties." It is edited by Messrs. E. W. Badger and W. J. Harrison, F.G.S.—a guarantee that it will be conducted with zeal and ability. The contents of the first number are varied and interesting. We extract the following from the notice to subscribers:—"As the cost of production is strictly limited to outlay for paper, printing, and unavoidable expenses (editorial services being entirely gratuitous), we confidently rely on the efforts of every subscriber who approves of our efforts in providing a useful medium for inter-communication between the naturalists of the midland counties, to aid us by his personal influence in extending our circulation." A very reasonable request, for the Journal cannot fail to be acceptable to those interested in natural-history subjects. It is published by Hardwicke and Bogue, 192, Piccadilly, London, and by Cornish, Brothers, New Street, Birmingham; also at the *Herald* office.

NOTES ON VILLA AND SUBURBAN GARDENING.

WE took advantage of the late frost to give all our Rose beds a good covering of manure, which will remain on the surface throughout the winter, and will be turned in after the spring pruning. We should have done this earlier in the season had there been sufficient frost to have prevented the wheelbarrows from cutting up the walks. Roses are in a very forward condition from the continuous mild weather, and many of the top buds are breaking into leaf. Although this is the case they should by no means be pruned yet, full directions for which will be given at its proper time.

Embrace every favourable opportunity to have ground in readiness for the sowing of the early important crops, for attention in this department must now be concentrated on the future, and our experiences of the past should help us to conquer the trials and difficulties that are sure to be in store for us.

Hotbeds and Frame Management.—There is no fixed rule that we are aware of as to the proper time for making hotbeds, and there are no appliances more useful in suburban gardens than frames. Our old cultivators had always to depend on the dung frame for their first early Cucumbers, and the most expert and attentive of them usually cut their first Cucumbers from the frame early in March. A brisk heat had constantly to be kept up, and every care taken of covering the frames with mats nightly. But these garden frames are not only useful for the raising of Cucumbers and Melons, but are indispensable for forcing Asparagus, early Potatoes, Carrots, Radishes and Lettuces, the propagating of bedding plants, and the raising of flower seeds, such as half-hardy annuals, &c.; in fact, it is surprising to many in these days, when hot-water appliances are so plentiful, what can be done with a good heap of hot stable manure and several garden frames. Leaves that were collected in the autumn should now be mixed with some long and fresh stable manure. The first thing is to throw it together in a close body to ferment. The more leaves that are mixed with the manure the less violent will be the heat, which for Potatoes, Carrots, and Radishes will be all the more suitable; but what is intended for the raising of Cucumbers may consist chiefly of stable manure. This will become very hot, and in a week or ten days will require carefully shaking out. Every lock that adheres together must be shaken to pieces, and water must be added as the turning proceeds if any portion has heated itself dry. In about another week it will require to be again turned over to sweeten. Where leaves are used liberally the heat will be more lasting. When the rank steam has escaped the making of the bed or beds may be proceeded with. Select a site which is fully exposed to the sun, then measure a space about a foot or 18 inches larger all round than the frame to be used. Place four sticks, one at each corner, as a guide, and commence building the bed, carefully shaking the material as before, employing some of the longest for building the sides, which should be made firm and neat as the work proceeds, also as upright as possible. A good lasting bed for Cucumbers will require to be made from 4 to 5 feet high, but for Potatoes, Carrots, &c., 3 feet will be ample; for these crops warmth is only required to first start them. With Cucumbers the case is very different, and a strong heat of 70° should if possible be retained throughout the early spring months. When the frame is placed on insert a pointed stick or two in the centre of the beds for testing the heat, and if found not too fierce half a barrowload of good light soil should be placed in hillocks in the centre of each light for planting the Cucumber plants in. We find it best to raise the plants in pots and to plant them out in the centre of these hillocks, adding more soil as the roots penetrate through the first lot of soil.

For growing early Potatoes the beds will require making in a similar manner, but having from 9 inches to a foot of soil spread all over the surface. While the bed is preparing lay some fair-sized early kidney Potatoes to sprout, and when all is settled plant them from a foot to 15 inches apart, sprinkling a little Radish seed (Wood's Early Scarlet is as good as any) over the surface and slightly rake it in. The Radishes will not interfere with the growth of the Potatoes. It will be necessary to give abundance of air on all favourable days to prevent both Potatoes and Radishes from becoming drawn. Early Horn Carrots are grown in a similar manner, and are always acceptable while young for soups, &c. Sometimes temporary frames are constructed for these crops, but more often ordinary frames are first used, and as the weather becomes warmer these frames are turned to use in various other ways. Where there is room for sowing a few Lettuce seeds there is none to surpass the Early Paris White. This is the most useful little Cabbage Lettuce for early work yet sent out; it is very tender and sweet, as well as quick "hearting."

WORK FOR THE WEEK.

HARDY FRUIT GARDEN.

PRUNING of Apple, Pear, Plum, and Cherry trees should now be in a forward state, and the requisite nailing of trees against walls attended to. This description of work should be concluded with all dispatch. The Apple and Pear produce fruit upon spurs, which are terminal buds upon short stubby shoots; these must be scrupulously retained, though in some instances they when old become too long and spreading. It is then desirable to thin them and bring them as near to the branches as possible by cutting out the straggling and long parts, retaining those nearest the branches. Pyramid and espalier trees are amenable to the same treatment. Pyramids often become crowded with wood in the centre of the trees: thin out so as to admit light and air to every branch. All spray if more than an inch long to be cut back to within half or three-quarters of an inch of its origin; the leading shoots to be cut back to 12 inches and the side shoots to 6 or 9 inches, in order to secure the well-furnishing of pyramids no

full-sized. Espalier or wall trees should have the leaders cut back to 12 inches and the side branches trained-in their full length. All shoots or spray not needed for extension or the formation of new parts to be pruned close. Plums and Cherries have the fruit for the most part borne on short spurs or shoots, the fruit buds being clustered around the shoot with a wood bud in the centre. These must not be shortened, but shoots that are more than 9 inches in length should be cut back to within two or three eyes of their base, and main shoots may be trained-in their full length. The Morello Cherry should have as much young wood laid-in as practicable, cutting out any long bare branches, but any shoots not amenable to training may be cut back to two or three eyes. Shoots of pyramidal Morellos not over 5 inches long need not be shortened, as too close pruning is not productive of a crop, especially if the trees are vigorous, they being more judiciously treated by summer-pinching and root-pruning. For securing the trees to walls we use medicated shreds, which are more durable than cloth, and any heavy strong branches are secured with tarred string. The surface soil should be removed down to the roots of any trees requiring assistance and a dressing of rich compost given, of which two-thirds should be loam, supplemented with a mulch of good manure: this will attract the roots near the surface and promote fruitfulness. In the case of unfruitful or very vigorous trees omit the dressing. Charred refuse and wood ashes in small quantity with some fresh loam are good for fruit trees of all kinds, supplying them with potash.

Apricots may be pruned in mild weather. Train-in young shoots thinly, cutting out those which are old, long, and bare, though it is not advisable to use the knife too freely, as it not infrequently results in extravasated sap or gum in the branches retained. Any shoots not available for nailing-in cut back to about an inch, retaining all the spurs unless very long, in which case it is necessary to shorten or remove them, the object being to keep the shoots and spurs close to the wall in order that they may derive the full benefit of its warmth. Make sure that none of the shoots or branches are bound too tightly. The pruning of Peach and Nectarine trees may stand over until next month, though we prefer to prune every description of fruit tree so soon as the leaves have fallen. Any trees infested with scale may be dressed with a composition formed of 1 lb. of soft soap and a quarter of a pint of spirit of turpentine to a gallon of boiling water, applying it carefully with a brush at a temperature not over 120°, and if a pound of tobacco powder be added it is good against every description of insect.

FRUIT HOUSES.

The early forcing of *Figs* is most successfully accomplished by trees in pots with a slight bottom heat, a bed of leaves producing a gentle and continued warmth which should not exceed 65°. The temperature of the house should be 55° to 50° at night and 60° to 65° by day with sun. The trees may be syringed twice a-day in bright weather, but in the morning only in dull weather. If the soil in the pots be dry it should be thoroughly moistened before plunging the pots in the bed. Those having trees planted out in the Fig house will have them dressed with a mixture for preventing red spider, the great enemy of the Fig. Pruning should be confined to the cutting-out of old bare wood and regulating the shoots. A little of the surface soil should be removed from the borders, replacing with fresh, the house being thoroughly cleaned. The border must be in a thoroughly moist state when forcing is commenced. Figs to do well require a light airy structure, and are deserving of something better than shaded positions beneath Vines.

Cucumbers.—Great care and attention are necessary to maintain healthy fruitful growth during the dark days. Do not push the plants by sharp firing or frequent supplies of strong liquid manure, but maintain an equable temperature and a due amount of moisture both at the root and in the atmosphere. Great variations in heat and moisture are prolific sources of stunted growth and yellow fruit. The night temperature in the severest weather ought not to be less than 65° in the morning, 70° at night, and 75° by day, with an advance of 10° or more from sun heat, attending to regulating the shoots frequently and not allowing the foliage and shoots to become overcrowded.

Strawberries to afford fruit in March should now be introduced to a house, where the pots can be placed on shelves at a not greater distance from the glass than 2 feet. We prefer the plants at 9 to 12 inches distance, and do not advise their being placed in heat until the pots have been plunged for a period of not less than three weeks in a bottom heat of not exceeding 65°. That afforded by leaves is most suitable. By the end of the time stated the bottom heat will have subsided and the roots will be in an active state. The plants may then be placed upon the shelves of a vinery started at the same time as the Strawberries were placed in the bed. We use turves 1½ to 2 inches thick for standing the pots upon. The plants root into the turf and are not so susceptible of injury by drought as plants with the roots solely confined to the pots. Plants for forcing should have well-developed crowns. Black Prince, which though small is still one of the best for early crops, Vicomtesse Héricart de Thury, La Grosse Sucrée, and Gold-finder are also certain setters. A little of the surface soil should

be removed from the pots and replaced by fresh loam with a half part of dissolved bones. Syringing may be practised twice a-day, and watering must be done carefully. The temperature should be 55° to 60° at night and 60° to 65° by day, rising to 75° or more from sun heat; after flowering the temperature may be increased.

PLANT HOUSES.

In the stove there will be little doing. It should be kept at a day temperature of 65° to 60° by day and 60° to 55° at night, the plants being carefully watered, evergreens being kept so moist as to prevent the foliage flagging, whilst deciduous plants may be kept so dry as to prevent the wood shrivelling. Clerodendrons, Allamandas, and Dipladenias having had a period of rest may be pruned and be sprinkled overhead twice a-day, affording moderate moisture at the roots: indeed Dipladenias should never be watered until dry, and when the roots have permeated the fresh soil water may be more frequently applied. All plants early in the season start more freely into growth in bottom heat, which should range from 80° up to 90°. Eucharises having had a season of rest, also Gardenias if set with buds, will, if placed in bottom heat and supplied with weak liquid manure, flower earlier than plants without the stimulus, thereby securing a prolonged bloom. A batch of Amaryllises, if introduced to bottom heat and kept moist, will start strongly and produce a fine display at an opportune time. Splendid new varieties of these gorgeous flowers have been raised by such firms as Messrs. Veitch, Williams, and Henderson.

Gloxinias may be potted. For early flowering remove most of the old soil and employ pots that will admit of an inch of soil being placed round the corms, which should only be just covered; water sparingly until growth takes place. Two-thirds of turfy loam and a third in equal parts of well-decayed manure or leaf soil and sandy peat, with a sixth of silver sand, will grow them well.

Ixoras should have sufficient water to maintain the foliage in good order. In a low temperature they do not succeed unless bottom heat be afforded, that in a measure lessening the necessity for so high an atmospheric temperature, which is fully 5° higher than is required by a majority of stove plants, and a corresponding degree of atmospheric moisture. Keep a strict look-out for insects, and destroy them by approved means, fumigation being the best for aphids and thrips, whilst scale and mealy bug yield to a solution of soft soap, 1 lb. dissolved in a gallon of water, and a quarter of a gill spirits of turpentine. Apply it with a brush or sponge, and syringe with clear water after the operation. Callas or Richardias should be brought forward in a temperature of 55° to 50° minimum, and 60° to 65° maximum. Bouvardias and Tree Carnations do not flower in winter with certainty in the temperature of a greenhouse, they requiring a somewhat warmer atmosphere, and are further assisted with weak liquid manure given occasionally.

Both the herbaceous Calceolarias and shrubby kinds are often neglected. Shift them into larger pots before the roots become closely matted; and Cinerarias to be moved into pots a size larger, keeping cool, moist, well ventilated, and free from insects. Pelargoniums not in their blooming pots to be placed therein without delay, keeping the shoots tied-out as required, and stopping those not well furnished or required for succession. They can hardly be kept too cool provided frost be excluded, nor have too light and airy a position.

TRADE CATALOGUES RECEIVED.

J. C. Wheeler & Sons, Gloucester.—“*Little Book*” illustrated, and *Short Select Seed List*.

James Dickson & Sons, 106, Eastgate Street, and Newton Nurseries, Chester.—*Catalogue of Vegetable and Flower Seeds, Garden Implements, &c.*

Dickson & Robinson, 12, Old Millgate, Manchester.—*Catalogue of Select Vegetable and Flower Seeds*.

Webb & Sons, Wordsley, Stourbridge.—*Illustrated Spring Catalogue of Vegetable, Flower, and Farm Seeds*.

James Wm. Mackey, 23, Upper Sackville Street, Dublin.—*Descriptive Seed Catalogue and Amateurs' Guide*.

W. H. Rogers, 182, High Street, Southampton.—*Descriptive Catalogue of Seeds and Garden Requisites*.

P. J. Looymans & Zonen, Oudenbosch, Holland.—*Catalogue of Hardy Ornamental Trees, Evergreens, and Flowering Shrubs*.

TO CORRESPONDENTS.

* * * All correspondence should be directed either to “The Editors” or to “The Publisher.” Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

BOOKS (A. Nelson).—“The Garden Manual,” published at our office, free by post if twenty postage stamps are enclosed with address.

REMOVING BULBS (Biceps).—Take them up now and plant them in pots, from which you can turn them out undisturbed when you are in possession of your new garden.

OLD BOOK (J. Davis).—It is one of Bradley's compilations and of no value.
POTATO DISEASE.—In answer to "A COUNTRY VICAR" (*Journal of Horticulture*, page 14), a correspondent informs us that Mr. W. G. Smith read a paper before the Scientific Committee of the Royal Horticultural Society on January 21st, 1874, in which he gave details of a number of experiments with diseased Potatoes and different preparations of carbolic acid. In every form and instance the carbolic acid proved a failure.

PEAS FOR SUCCESSION (A Beginner).—Quantity having to be considered before quality, we advise you to grow First and Best, sowing so soon after the middle of February as the weather permits, and again early in March, at the same time making a sowing of Filibasket; after this March sowing a sowing should be made every fortnight or three weeks until the middle of June, of Dr. Maclean, Maclean's Wonderful, and Veitch's Perfection up to the middle of May, and afterwards of Prisetaker, Green Marrow, Culverwell's Prolific Marrow, and Ne Plus Ultra. Your soil being light sow in well-manured trenches after April, and water abundantly in dry weather, employing liquid manure poured in shallow trenches along the sides of the rows, not upon the stems of the plants.

CAULIFLOWER AND BROCCOLI FOR SUCCESSION (Idem).—Cauliflower you may have in frames or handlights; if not, sow seed at once in a pan or box and place in gentle heat, pricking out the plants in boxes to be placed in frames. These plants if planted out in April will come in in June. Sow again in March on a warm border, and every three weeks from that sowing up to the close of May, the last spring sowing being made in the third week or early part of the fourth week in that month. Sow for wintering in frames or under handlights the third week in August. Walcheren is the best variety, but is preceded by Early London. Early in April sow Veitch's Self-protecting Autumn Broccoli, which is to be taken up when having heads 4 to 6 inches across and planted in frames, affording protection in severe weather, and about the early part of April sow Penzance Early White, Cooling's Matchless, Leamington, and Lauder's Goshen Late White Broccoli.

CABBAGES, CAULIFLOWERS, &c., CLUBBING (J. W.).—It is caused by the larva (small white maggot) of a weevil, and is very common in light sandy soils, especially those long under crops of the Brassica family. We are much troubled with it ourselves, and find common salt a good application at the rate of twenty bushels per acre; also nitrate of soda, $1\frac{1}{2}$ cwt. per acre, or 1 lb. to 30 square yards applied prior to planting; gas lime twelve bushels per acre spread on the surface and pointed in before planting is, however, a better preventive than salt or the nitrate of soda. At planting time the root stems should be examined, and if they have warts or knobs upon them they should be opened and the grub inside them removed, planting afterwards, the growth of the plants not being much retarded. Frequent transplantation is good, as it tends to a sturdy ligneous growth and admits of more frequent examination of the stems.

HOYA IMPERIALIS CASTING FLOWER BUDS (A. B.).—We think the roots are in an inactive state, occasioned probably by a wet state of the soil and the recent repotting. Water more sparingly, affording slight bottom heat if practicable with a view to healthy root-action, with which and a moderately moist and brisk heat the flowers ought not to drop.

PLANTS FOR STOVE (Economy).—*Foliage:* Croton Weismanni, C. Johannis, Dieffenbachia Wreli superba, Dracaena Cooperi, D. reginae, Maranta rosea picta, M. illustris, Pandanus Veitchii, Chamaedorea elegantissima, Thrinax elegans, Cocos Weddelliana, and Areca Verschaffeltii. *Flowering:* Anthurium Schertzerianum, Aphelandra aurantiaca Rozeii, Centropogon Lucayanus, Dalechampia Rozeiliana rosea, Eucharis amazonica, Francisca calycina major, Gardenia florida intermedia, Gesnera exoniensis, Hoya bella, Imantophyllum minutum, Ixora acuminata, I. Williamsi, Poinsettia pulcherrima, Rondeletia speciosa major, Scutellaria Mociniana, Tabernaemontana coronaria flore-pleno, and Thyrsacanthus rutilans. We have omitted climbers, but you may probably wish a few such as Stephanotis floribunda, Bougainvillea glabra, Clerodendron Balfouri, and Allamanda Chelonii. We advise you to commence with a few only of those named, and fill up with Gloxinias, Achimenes, Begonias, and Caladiums. Our "Indoor Gardening" will suit you, post free for 1s. 7d.

LIME RUBBISH FOR ROSES (J. S. B.).—If your soil be very strong it would improve its texture, but to a light soil it would do no good other than in being moisture-holding. Use it moderately if at all, and treat liberally with manure.

ANTHURIUM ANDREANUM.—Several correspondents ask where this can be obtained. We shall be obliged by being informed.

ARRANGEMENT OF PLANTS IN FLOWER BEDS (Constant Subscriber).—Some notes on this subject will shortly be published.

LILAC ZONAL PELARGONIUMS (Amateur).—One of the best of the lilac-tinted pinks that we are acquainted with is Heather Bell, which was raised by Dr. Denny. It has good trusses and well-formed flowers. The colour is very distinct and pleasing, and the habit of the plant is dwarf and free.

EARLY PEACH AND NECTARINE FOR ORCHARD HOUSE (J. B. B.).—One of the best early Peaches is Hale's Early. It is an American variety and is suitable for growing under glass and on walls. The best early Nectarine is Lord Napier, which was raised by Mr. Rivers. It is not only the earliest but one of the finest Nectarines in cultivation, and the tree is a good grower and bearer.

GROS COLMAN GRAPE (Clericus).—It will keep well until Christmas and makes a noble dish. It is the largest of all black Grapes, and when grown well and ripened early is of fairly good quality. Where the gratification of the eye is considered a Vine of Gros Colman is worthy of being grown.

LIGHT-COLOURED CLEMATISSES (Ightham).—The following of the lanuginosa type are effective:—Lady Caroline Nevill, flesh white, mauve bars; Lanuginosa candida, greyish white; Lanuginosa nives, pure white; and Beauty of Surrey, greyish blue. Of the Patens type Miss Bateman, white, chocolate anthers; Fair Rosamond, bluish white, faint red bar; and Vesta, white with purplish stamens, are good and inexpensive. They are hardy and free, flowering earlier than the lanuginosa varieties.

EARLY TOMATOES (A New Subscriber).—The earliest variety is Early Gem. The plant is of slender growth, and the fruit is small. It is useful for growing in pots for early produce. Orangefield is dwarf, early, and prolific, and is good for pot culture. Vick's Criterion is a very fine new Tomato which ripens early. It is very prolific, smooth, and well coloured. It is well worthy of cultivation. Green Gage is the best of the yellow-fruited varieties, and is moderately early.

ASPLENIUM LUCIDUM (R. Watson).—The dust is the spores of the Fern.

RAISING LOBELIAS (Juno).—Seed of Lobelia speciosa cannot be sown too early provided conveniences are afforded for growing the plants on until they can be placed in cold frames early in May. Unless you have a house, such as a warm greenhouse, in which you can place the seed pans after the seedlings appear in the cucumber frame, we should defer the sowing of the seed until March. When once the seedlings appear they must have a steady unchecked growth. Sow the seed thinly in light rich soil, covering very slightly and keeping regularly moist. Dry soil occasionally and thickly sowing the seed are prime sources of failure in raising Lobelias.

WINTER TREATMENT OF IRESINE LINDENI (C. M. D.).—Any glass structure from which frost and excessive damp is excluded will answer for wintering the Iresine. A few plants kept in well-drained pots among the Geraniums and other bedding plants will afford an abundant supply of cuttings for spring propagation, especially if the store plants are shifted now into larger pots and placed in heat towards the end of the month. Do not fail to remember that no heat beyond the temperature of a greenhouse is required, unless it becomes necessary to accelerate growth for a supply of cuttings. The book you require is the "Cottage Gardeners' Dictionary."

CAMELLIA SHEDDING ITS FLOWER BUDS (W. M. G.).—Bud-shedding is caused by drought, overwatering, or debility. As your plant is so vigorous we attribute the mischief to one or both of the first two causes, knowing as we do that a day or two's drought or overwatering only once at that critical period when the buds commence swelling for full expansion will cause all the buds to fall off. Most probably the evil arose from an overdose of water, and notwithstanding the healthy condition of the plant we should be disposed to examine and remedy any defect in its drainage on the approach of the next season of growth, and then under such care and painstaking as you evidently bestow upon your plants plenty of flowers will most likely crown your efforts next season.

NAME OF FRUIT (Connaught Subscriber).—Doyenné d'Éclair.

NAMES OF PLANTS (X. Y. Z.).—Euphorbia jacquiniæflora. (R. F. B.). We cannot name from a scrap of leaf. (A. H. S.).—The specimens were not numbered for reference.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

MANAGEMENT OF FARM HORSES.

IN those cases where people do not breed their own horses it is best to select animals of sufficient weight and size, say from 16 $\frac{1}{2}$ to 17 hands in height, with plenty of substance and bone, but at the same time with clean legs and activity; in fact we may well adopt the good-bred Clydesdale as our pattern, and, if possible, the animal when purchased should not be under four nor over five years of age, and if an arrangement can be made for a few days or a week's trial so much the better. In the event of farmers breeding horses for their own use, the "Clydesdale" style is still the best. Horses have now been very dear for ten or twelve years past, and some 80 or 40 per cent. higher than formerly; the importations from France, however, have been very acceptable, and have been the cause of keeping the price more moderate. A large portion of these, however, are but ill adapted for farm work, not being sufficiently heavy and powerful, but are more fitting for light work and van purposes; yet many farmers continue to buy them because they cost less money than heavy well-bred English horses. We recommend in farm work two horses costing sixty guineas each as being more profitable than three costing forty guineas each, for although the total cost is the same, in the former case you have only two lives at stake instead of three, only two animals to feed, harness, shoe, &c., instead of three, and less labour in attendance. All these are important items, and we know from experience that the two powerful horses will do the same work as the three lighter animals if properly fed and suitable implements are provided. On a small farm of forty or fifty acres arable with a few acres of grass land, if the soil is dry and friable, the two horses alluded to are equal to any work on the farm, two to the plough in fallow-ploughing in winter and spring, and one to the plough in summer work, or two to the double-furrow plough. Again, instead of heavy scarifying with Coleman's implement, let a strong iron horse hoe with tines and shares be used with one or two horses according to the work to be done; in fact, on an occupation of sixty or seventy acres where some portion is grass land as well as the fifty acres above named, two horses with a lighter active horse for the market cart and light daily work on the farm are quite sufficient to keep all the work in a forward and decent condition. Farm horses, in our opinion, should never be turned out to graze. In our climate, even in the summer months, we often have a white frost at night; how can we expect

that animals in hard work and excitement during the heat of the day can lie down in the open fields or pastures at night-time without damage to their health? and although it may not be discovered immediately, depend upon it the seeds of disease are sown under such a system of management, and will certainly crop out in ill health sooner or later. Besides, how many more accidents to life and limb occur to horses turned out to graze than those carefully boxed or tethered in well-constructed stables. The question of food likewise is in favour of feeding at the stalls, because an acre of grass or green fodder of any kind will go much further and with less waste than when fed in the field. Watering the animals is of more importance than is often supposed. We never allow a horse to drink at a pond or trough, believing that when they take their fill without stint during hard work it is often the cause of broken wind, and it is only possible to regulate the quantity when they have water given at the stalls.

We will now refer to the accommodation for horses engaged in agriculture, and unfortunately the stables are often as bad as they can be both for the health of the animals and the saving of the manure. When we consider the annual depreciation of the value of a horse under the best of management to amount to four or five guineas it shows at once the importance of a well-built and well-placed stable. It is usual to see on the majority of farms the stable badly ventilated, and the floor of the stalls pitched with large or small stones irregularly laid and subject to accumulations between them of rotten straw and urine giving off foul air continually, so much so that on opening a stable door of a morning when the attendant enters he is often obliged to turn his head another way, the ammoniacal vapour being so powerful as to painfully affect his eyes. If this is the result to the attendant, what must be the effect on the health of the horses who are breathing foul air often for many hours in succession? Need we wonder at the number of horses engaged in agriculture losing their eyesight? Look again at the stables for the animals to lie down upon; in fact they do not lie down when they ought, or otherwise would if they had a good bed, and is it not a loss if they do not take a proper amount of rest? The hard stables are also about the worst floor they can stand upon, and often injure the feet by sandcracks and broken hoofs, with an increase in the cost of shoeing. Descriptive designs for stables, &c., in our next.

POULTRY IN 1877.

It is always pleasing and generally instructive to look back over the events and progress of the past year. Putting aside the more exciting topic of politics, even in the quiet walk of the garden, the farm, or the poultry yard, with which we are now concerned, all years are not the same. It is well they are not, for much of the amusement of such occupations is owing to their constant variety. Some years are more remarkable for the forwardness and early maturity of the birds reared, others for greater size accompanied by backwardness. The year just past has not been an uneventful one for the poultry fancier. Two bad hatching seasons had preceded it, and last year a mysterious epidemic appeared which at one time threatened to become a scourge to the yards of the whole kingdom. Particular diseases among human beings seem to have their cycles. Whether old enemies appear under fresh external forms and new names we are not sufficiently scientific to say, but certainly gout and rheumatism have succeeded ague and influenza, while diphtheria and blood-poisoning were unheard of fifty years ago. In the same way the maladies of the poultry yard have changed, or at least our observation of them has become more accurate. With the old hen-wives all ailments were the pip or the roup. A smattering of medical practice in poultry brought us to the knowledge of roup, and for a certain time we referred to that complaint all diseases from a slight sneeze—equivalent to a cold in human beings—to an advanced stage of what would be parallel to consumption. Probably many like-diseases were confused under one name, and this "new disease" was only one of the genus. Be that as it may, it came in a most destructive form, and was intensely infectious. Its ravages were chiefly confined to the north of England, or to yards whither it had been imported from northern shows. One or two selfish exhibitors, who confessedly had it raging in their yards, sent infected birds to Bristol and other shows, and so did their best to cause its spreading; but, fortunately, in the past year its virulence seemed to pass away; and though we hear that many yards are not free from its traces, yet it comes in a modified and curable form.

The early part of the year was extremely mild though damp, and, contrary to what we should have expected, it was reported that a great number of eggs were clear, and broods consequently small. The unseasonable warmth of the winter and early spring was succeeded by what has so aptly been called "the still sharper English spring." The east winds of April and May were most destructive to early broods, and the result was that but few early birds appeared at the chicken shows; but those which had braved the inclement season were for the most part forward and very fine. If possible these peculiarities of seasons should be taken into account by promoters of chicken shows. Unfortunately in the

past year when chickens in general were backward the great shows for them were held early and near together, so that the few early birds were again and again pitted against each other, while most of those which will probably turn out the finest adults have not been seen, or have competed in unequal contest with old birds at some of the later shows. But we will reserve this subject for another communication, in which we hope to enter fully into the position of poultry shows. The autumn has been mild and has favoured the growth of late-hatched birds. We have, ourselves, cockerels and pullets hatched in July still progressing well in the new year, and promising ere long to rival the best April hatches. But we must pass from a general review of the poultry year to particular breeds.

Dorkings, as a rule, have quite held their own. This old English breed must in some peculiar way be suitable to our climate and national requirements, for among all the changes of fashion it never loses its place. The best birds always command high prices, while specimens deficient in exhibition points find a market for the improvement of farm stock. We regret at Birmingham to see a falling-off from former years in number and quality, though this observation does not apply to the Whites. There eight or ten years ago the show was wonderful; many of the noble landowners of the midland counties who showed nowhere else sent to Birmingham, and we saw and have bought there many a grand bird fresh from a park run. This is much changed, though probably rather on account of shortcomings in the shows' arrangement than from any falling of the breed's popularity. Dorkings do not stand confinement, and Birmingham is a long, far too long, a show. The type of bird, too, has changed, and in our opinion not for the better. A slight increase in weight has been obtained at the expense of longer legs and less round breast. Now and then a well-shaped bird appears, and every fancier exclaims "A true Dorking shape!" as if the majority of birds could not be bred to that type. The dark-coloured birds, too, have been judged far too much for feather, and dark feet (a terrible eyesore in a Dorking) have followed the fashionable dark plumage. Silver-Greys are about stationary, but Whites have made immense strides during the last three years; both in size, colour, and comb they are immeasurably superior to the Whites of five years ago. Could the classes of dark Dorkings at Birmingham in 1877 be mixed with those of 1867 we believe that the prizes would for the most part fall to the latter; while in the case of Whites we feel confident that the birds of the present day would utterly distance their progenitors of ten years ago. Cuckoos do not progress in favour to judge by the Surrey shows, of which they are the speciality. They have been too much crossed for size, hence their produce is uncertain in marking, and this disgusts breeders. Those shown are generally up to a fair standard.

In the year just passed have been shown some of the best Cochins that it has ever been our fortune to see, a few of them uniting the greater size and heavier leg-feathering of the more modern Cochin type with the characteristic form of the earlier type. Of late years we have regretted to see long legs, long backs, and tapering tails often in the highest place just on account of the bird's size; but some of the great breeders seem now to have mastered the combination of size and form. We are specially thinking of Mr. Proctor's two renowned Buff cocks and of Mr. Darby's Whites of both sexes. Fashion seems to favour the paler hues in Buff hens even when accompanied with great irregularity in colouring. This is to be deprecated, for surely a rich and even colour is one of the special beauties of a Buff Cochin hen. We should like to see Cinnamons again amongst them, and have been pleased of late to observe here and there a Grouse hen among the Partridge. Blacks are making great progress. The first cockerel at Birmingham struck us as being the Black nearest in shape to a good Buff that we had ever seen, and capital in lustre too. Who could look at the motley group of Langshans there and wish to perpetuate the species at the expense of the sheeny symmetrical Black Cochins?

The decadence of Dark Brahmas is perhaps a sore subject for some, but it is none the less a fact. The decrease in entries at the Crystal Palace speaks for itself. The fact is, an exaggerated estimate was formed of the merits of the breed, and a *furor* in its favour was got up resembling in a minor degree the Cochin mania. They have been found excessively difficult to breed to any particular type, a fact which has always inclined us to the side of those who believe in their mongrel origin, and hence a reaction has followed. To obtain a particular and certainly most beautiful type of pencilling in the hens has been the great object of most of their admirers, and this has been attained at the expense of size and form. Mr. Lingwood and one or two others have continued to breed for form as well as colour, regardless of the fashion, and we hope they will soon be rewarded. Though the marking of the hens is at present almost perfection, the cocks we consider greatly inferior to those of five years ago. Vulture-hocked birds, again, appear in the prize list, and rightly we think, for their exclusion puts out many of the otherwise finest specimens, and is an encouragement to such frauds as that exposed in a prize cockerel at the Crystal Palace in 1876. The Light variety has not declined in numbers to such an extent as the Dark, and

in quality quite keeps up its position. They are more shapely and have finer leg-feathering than they had a few years ago. We hear from the highest authorities that really good specimens of both varieties continue to be greatly in demand at high prices in spite of this decrease in the number exhibited.

Success in the Game fancy is still confined to few, but this we believe chiefly results from the fact that the breed is fortunate enough to possess a few most enthusiastic admirers, who breed it in no haphazard but a truly scientific way, with pedigrees as carefully drawn as those of thoroughbreds or thoroughbreds. Much controversy has arisen as to their method of marking their birds, which is in some cases too patent, and might bring them under the rule (if strictly carried out) against marked birds. We do not for a moment suppose that the eminent breeders who mark in this way have had any other object in view than to distinguish birds privately for themselves; but why it should be impossible to mark Game like any other breed (which we have found perfectly easy) in ways that no one can detect without difficulty, we cannot understand. We commend to their attention the fact that considering the somewhat unjust censure which has of late often been passed on poultry fanciers in general in consequence of the dishonesty of a few, that it behoves us not only to avoid all dishonourable conduct but everything which may by enemies be distorted into suspicion of it.

The chief event of the year in Game has been the production by Mr. Pope of a Black Red cockerel, pronounced by the greatest judges to be the most perfect specimen of the modern type of Game cock ever seen. At Oxford he changed hands for the great sum of fifty guineas, and at the Crystal Palace he again did so for the almost unprecedented one of one hundred guineas. This is an age in which majorities tyrannise over minorities, and so the less popular breeds bid fair to become extinct. White and Black Game become fewer and fewer, and the old Brassy-winged and Dun birds are, in the show pen at least, almost extinct.

A SIMPLE CHICKEN COOP.

"BEING engaged in raising chickens," says a correspondent of the *Rural New Yorker*, "I found it necessary to make cheap coops to keep them in for a few weeks. I take an old barrel and tack every hoop on each side of a seam between the staves with an

Fig. 7.

inch wrought nail; after clinching the nails I saw the hoops off on the seam. Then I spread the barrel open, as in the annexed figure, by cutting a board about 20 inches long for the back of the coop, and two small pieces to tack laths on for the front part. The upper section of the back is fastened with leather hinges, so that I can open it at pleasure."

POULTRY SHOWS.

THE twelfth annual show at WOLVERHAMPTON is fixed for the 26th and 28th inst. The schedule has reached us; it is as liberal as its predecessors. Nearly £200, with the addition of several silver cups, is offered for competition in the poultry and Pigeon classes. This Show has always been popular and well managed, and we trust it will be better supported than last year, as it is one we should not like to spare.

The WELLINGBOROUGH schedule has also been issued. The Show is fixed for the 2nd and 4th of February. Like Wolverhampton it includes a Sunday. The prizes amount to about £100, with the addition of some objectionable point cups, which are the beacons that generally attract the dealers and warn the amateurs to keep clear. With this exception the classification is good.

PAISLEY POULTRY, &c., SHOW.

THIS was held on the 1st and 2nd inst. in the Drill Hall. It was the largest and best Show the Society has ever held, the entries numbering in all 1106.

POULTRY.—SPANISH.—1, J. Hogg. 2, A. Scott. 3, W. Cuthbertson. 4, R. Begg. *Chickens*.—1 and 4, Mrs. H. Gracie. 2, T. B. Retson. 3, J. E. Crawford. *Hens*.—1, T. B. Retson. 2, A. Scott. 3, J. Park. 4, W. Greenshield. **DORKINGS**.—Coloured.—1 and Special, D. Galbraith. 2, J. Paul. 3, W. Wallace. 4, E. Hunter. *Chickens*.—1 and 3, J. Adam. 2, R. Bertram. 4, J. Paul. *White*.—1, R. JUDGES.—*Poultry*: Mr. J. Stuart, Thistlebank, Helensburgh; Mr. W. Jamieson, Gargunnoch, Stirlingshire; Mr. R. Stewart, Blairadam, Kinross; Mr. J. Aitchison, Cambuslang; Mr. A. Glendinning, Strathblane; Mr. J. Sharp, Johnstone. *Pigeons*: Mr. J. Grierson, Strathaven; Mr. J. Glen, High Bushy Hill, Cambuslang. *Canaries, &c.*: Mr. T. Buchanan, Glasgow; Mr. J. McAllister, Glasgow; Mr. D. Duncan, Carron, Larbert; Mr. R. Crawford, Kilbirnie; Mr. J. McPherson, Paisley; Mr. W. White, Renfrew; Mr. A. Howe, Paisley; Mr. T. Fernie, Paisley.

PRESTON SHOW OF POULTRY, &c.

THE second Show was held in the Corn Exchange at Preston on Wednesday and Thursday last. The building is a most excellent one for the purpose, large, well lighted and ventilated, and capable of accommodating an enormous number of birds. In the present case the entries amounted to upwards of 800, of which poultry had 800, Pigeons 400, Rabbits 114, and Cats 20. In poultry there were some very good classes, while others were poor.

Dorkings were a fair lot; while *Cochins* of both classes were very good. In *Game* the cup went to a Brown Red chicken which was comparatively young and raw; the second in that class being a well-built old cock. The rest of *Game* only of moderate quality and few in number. *Hamburgs* not numerous but very good; the cup for the section was, however, awarded to *Spanish*. The *Geese*, *Turkeys*, and *Ducks* were about the best section of poultry, almost every pen deserving a notice. Entries were small in all the *Bantams*, and with the exception of the winners the quality was not high. In the Variety class were some excellent Cuckoo, Pekin, and Blacks, the cup going to a smart Black Red cock.

In *Pigeons* there were five classes for Pouters, some of the birds showing well, but as a rule looking quite flat. Carriers were very good in all classes, especially in the two classes for Blacks, the winners being uncommonly heavy wattled and well shown. Carriers, young, an excellent class. Barbs, cocks, first and second Black, and third Red; the winners in hens all Blacks. Barbs bred in 1877 were a good lot, and in our opinion not one old bird was shown. Dragons Blue or Silver very good; the first a grand Blue cock, as also the second, the third being a Silver. Red or Yellow were but a moderate lot, while those of any other colour were decidedly poor, and young birds very good. Antwerps had five classes, and there were some very good birds. Tumblers, Almond, one of the best classes in the Show, both head and feather properties a treat to see. Any other Short-faces, the winners were Agates and Kites. Jacobins Red or Yellow were a grand class, almost every bird deserving a notice. Jacobins any other colour

Mule, which was second on this occasion, although a winner on previous occasions, and exhibited by Capt. John Gordon.

There were throughout the Show many fine specimens of the Scotch Fancy, Belgian, and Norwich birds, the latter particularly, exhibited by Mr. Blair, being exceedingly high in colour, his Buff Norwich especially, and also a Buff-crested bird, both of which were awarded "specials" as being the best birds of their respective breeds in the Show. They would have done credit to any bird-exhibitor on this side of the border. The Lizards and Cinnamons were fair specimens, the Lizards in particular being above par. The show of British Birds, especially Goldfinches, Linnets, Siskins, and the Starlings, Blackbirds, and Thrushes in the "Any other variety of British Birds," were in fine plumage. Foreign Birds formed a showy class, but the first-prize King Parrot was the king of the lot.—GEO. J. BARNESBY.

CAGE BIRDS.

YOUNG.—BELGIANS.—*Clear or Ticked Buff*.—1, W. Donald. 2, 3, and *etc.* Miss I. Watt. **SCOTCH FANCY.**—*Clear or Ticked Buff*.—1 and 3, J. Taylor. 2, P. Lyon. *Variegated*.—1, 2, and 3, W. Duncan. **NORWICH.**—1, J. Blair. 2 and 3, G. Chalmers. *etc.* H. B. Gibb. **W. SILVER.**—*Clear Buff*.—1, J. Blair. 2 and 3, J. Balfour. *Marked Buff*.—1, J. Blair. 2 and 3, W. Silver. *Ticked, Unevenly-marked, or Variegated Yellow*.—1, 2, and 3, J. Balfour. *etc.* H. B. Gibb. *Ticked, Unevenly-marked, or Variegated Buff*.—1, J. Balfour. 2, G. Ross. 3, J. Blair. *etc.* J. Bisset, P. Lyon. *Crested Yellow or Yellow-marked*.—1, J. Blair. 2, P. Lyon. 3, J. Murray. *etc.* G. Ross. *Crested Buff or Buff-marked*.—1, J. Blair. 2 and 3, W. Silver. *etc.* G. Ross. **W. Lyon. 2 and *etc.* J. Smith. 3, W. McGregor. **MACAW, COCKATOO, AND ALL KEY BIRDS.**—1, J. H. H. 2 and *etc.* A. Cameron. 3, J. Lyle. **FOREIGN BIRDS.**—*Any other variety*.—1, W. Silver. 2 and 3, A. Middleton.

SPECIAL PRIZES.—Gold Medals: Messrs. W. Silver, J. Calder, and J. Blair. *Silver Medals:* Messrs. Duncan, J. Blair (3), W. Silver (2), J. Balfour (2), C. Gouck, Hon. Mrs. Arbuthnot, and A. Knowles; A. Barnett and R. Sutherland being equal.

VARIETIES.

We are glad to announce that our staff has been strengthened by the addition of Mr. O. E. Cresswell of Earley Wood, Bagshot, who will contribute articles on poultry management and exhibiting.

— **TO MAKE A NEST EGG.**—Take an ordinary hen's egg, break a small hole in the small end about three-eighths of an inch in diameter, extract the contents, and, after it is thoroughly clear inside fill it with powdered slaked lime, tamping it in order to make it contain as much as possible. After it is full seal it up with plaster of Paris, and you have a nest egg which cannot be distinguished by the hen from the other eggs, and one which will not crack like other eggs by being frozen.—(*Scientific American*.)

— **A GOOD AUTHORITY** writing on dairy farming states that with a good stock of cows, and the details wrought out in a proper manner, the dairy should pay as well, if not better, on many farms than any other system of farming—the present prices and future prospects of the produce being all in their favour, having less foreign competition to meet with in the market than any other product of the farm.

— **ACCORDING** to statistics compiled by the French Government, the average cereal product of Europe is 4,995,000,000 bushels. Of this Germany furnishes 742,500,000 bushels, and Austria 450,000,000 bushels. The latest reliable estimates for the United States give the cereal yield of the present year at 1,600,000,000 bushels. This, says an American contemporary, shows that the United States has at last taken rank as the greatest cereal-producing country in the world. Russia has in the past held the palm; this year she will fall considerably below. The American average export of grain and flour for some years past has been about \$100,000,000. This year it will considerably exceed this sum. This year the American wheat export alone will reach more than 80,000,000 bushels of wheat. Last year it was 52,697,899 bushels,

and in 1868 only 14,597,585 bushels. Such progress as is here recorded cannot fail to exercise an important influence on this country.

— **THE** following estimate of the extent of the disease existing in the potato crop of 1877 has been furnished to the *Mark Lane Express* by 396 correspondents from various districts in every county in England and six counties in Wales:—

1877.	No. of Districts.
Free from disease	4
One-eighth diseased	28
One-fourth diseased	70
Three-eighths diseased	51
Half diseased	132
Five-eighths diseased	84
Three-fourths diseased	39
Seven-eighths diseased	15
Failure	3

Total advices..... 396

The estimate for the preceding year was as follows:—

1876.	No. of Districts.
Free from disease	25
One-eighth diseased	49
One-fourth diseased	93
Three-eighths diseased	63
Half diseased	91
Five-eighths diseased	42
Three-fourths diseased	30
Seven-eighths diseased	3
Failure	0

Total advices..... 396

— **IN** relation to breeds Mr. E. H. Seward, an experienced American dairy farmer, has said the Devons as a class are not deep milkers, yet individuals and especially grades were good. The Ayrshires will give a large quantity of milk for the food consumed. They do not transmit their good qualities in crossing. It is an objection. The Alderneys or Jerseys give rich milk, but not a large quantity. They are good butter cows, but not well adapted for cold districts. We want quantity in our dairies for making cheese. The Short-horn really spring from the Dutch or Holstein, and the old Teeswater. Much of their value to-day as dairy cattle he believed was due to this Dutch blood. They were years ago known as great milkers. The Hollanders are good judges of milking cattle. They want a good girth, good hind quarters, a short neck, and fine development of udder and milkveins. [For a small establishment we know no breed to surpass the Kerry for dairy purposes. They are far hardier, and give more milk, and nearly of equal quality to the Alderney.—*Eds.*]

— **THE** liquid voidings of animals are worth more—good authorities say one-sixth more—pound for pound than the solid excrements, and are saved with greater care by the best farmers and gardeners. All the leaks in the stable are not in the roof; those often in the floor are quite as objectionable, and are the cause of a great deal of wastage. Make the stable floor tight, with a gutter at the heels of the stock to carry off the urine to an adjacent tank, or into a heap of muck or other absorbent.

— **WHEAT** culture in olden time, as described by Fitzherbert in the reign of "bluff King Hal," was carried on much in the same way as at the present day. Neither were the farmers of those times ignorant of some of the shrewd practices of those of to-day, nor of the reasons for them. For instance, under the article "To falowe," Fitzherbert says: "The greater the clottes (clouds) the better wheate, for the clottes keep the wheate warme all wynter; and at March they will melte and breake and fal in many small peces, the whiche is a new dongynge and refreshynge of the corne."

— **FOWLS** drink water freely, but they know just how much they need, and when they have access to the fluid clean, sweet, and fresh, they imbibe no more than is good for them. It is, therefore, unnecessary to mix your dough too thin and sloppy at the morning feeding. Have the meal well scalded, and feed the mixture to the stock stiff and dry comparatively. This feed should generally be composed of both corn and rye meal, with vegetables—say one-third each. In our own practice we have found this preferable both for the birds and as an economical provision for the old or the growing stock. A little pepper occasionally in this dough, and always salt, will improve the mess.—(*Poultry World*.)

— **A NEVADA** shepherd counts his sheep by means of a dial plate register. They are driven singly over a narrow platform, and as each steps off the dial marks the number.

— **THE** potato crop of America is estimated at 200,000,000 bushels. These are 225 factories reported in the eastern States engaged in the manufacture of starch from potatoes. These consume about 3,000,000 bushels annually.

— **THE** farmer who calculates to make his living by farming cannot afford to lose a knowledge of the best methods in practice, and he cannot hope to learn these methods by his own experience, even if that experience be a rich one. He cannot afford to lose

the money which he certainly will by selling his produce blindly, without knowing the conditions of the market and the things which affect its rise and fall. If he is successful without reading, it is because he gets his information from those who have taken advantage of agricultural literature and have turned its teachings to profitable account.

CHICKWEED, says the *Portland Press*, is an excellent barometer. When the flowers expand fully there need be no fear of rain for several hours. Should it continue in that condition no rain will disturb the day. When it half conceals its miniature flowers the day is sure to be showery, and if it entirely shuts up, or veils the white flower with its green mantle, let the traveller put on his great coat.

BEE-KEEPING IN KANSAS.

THE following extracts from a letter just received from an old neighbour of mine, who has formed a new home for himself in Central North America, appears to me sufficiently interesting to find a place in this Journal:—

"This is a great country for bees, and the bee-keepers 'go into it' largely. There are two close to me with 100 or 150 stocks each, and many with fifty downwards. I do not see any very great improvements upon the plans we adopted, except that the bars we formerly used are changed into entire frames, and the hives are deeper and the supers larger than ours. They quite despise the use of any covering over the combs or protection over themselves. They simply take off the lid or outside cover of the hive and the bees are all exposed to view. Of course, they are first treated to a plentiful dose of smoke made from a bundle of cotton rags tied-up like a large squib or rocket, about 8 or 9 inches long and an inch or so in diameter, and they blow the smoke amongst the bees until they are stupefied or nearly so, and then commence handling the combs, which they take out and examine, remove or exchange, according to the object aimed at.

"Their mode of increasing stocks is principally by taking about four or five frames out of a full stock and putting them into an empty hive, and, of course, filling-up the other hive with empty frames. All you have to attend to is to see which hive gets the queen, and that the other is in a forward state to soon hatch-out one. The two hives are thus soon made complete, and in a good season you can repeat the operation, thus making four hives out of one.

"The other plan followed is the nucleus one—namely, by cutting-out a queen with an inch or two of comb round her, and fitting it into another comb with three or four frames full of bees. This plan answers admirably if fairly well done, but the bee-dealers are too prone to sell you a swarm made-up of a nucleus queen and only, perhaps, a couple of frames sparsely sprinkled with bees, and the rest of the hive empty frames. It ought to be done pretty early in the season.

"The only other modes are the natural ones of swarming and drumming. The former they cannot altogether help; the latter is often practised, particularly by those who use the extractor. Bee-masters do not like parting with their combs, they extract all the honey from them during the honey-making season, and put back the combs to be refilled, and they do this with the combs several times, taking care to keep well within the limit of the honey gathered, so as not to leave the bees with empty combs at the close of the season. It is, of course, an admirable plan, as you are ready at the commencement of the season to place your supers on the hives with all the combs ready made.

"Extracted honey sells for 25 cents, or 1s. per lb., and honey in the comb at the same price—it is a matter of calculation. The supers are large, the same in size as the hives themselves, but not so deep. The ordinary dimensions of hives is 14 inches square in the clear, a 14-inch cube, the frames about a foot deep, and an allowance is made in the width for the bees to travel all round them say a quarter inch on each side. The supers are about 7 inches in the clear in depth. The same top or cover fits both hive and super, and when the super is removed it goes over the hive.

"The Californian supers are of the same depth, but two go to the hive, simply made-up of frame with no top. They sell the super, comb and all, for 25 cents per lb. You buy the super with the honey.* The wood of each super weighs about a pound. Eight frames are tacked together with no top or ends. The bees come up through the bars. It is a good, easy, and cheap way of making them. The shop people cut off a frame or two for their customers, about 1½ lb. in each frame. If you get off four of these supers from your hive in the season it is not bad work—about 48 lbs. to sell. Two of them go nicely in your top hive, which you would otherwise use for a super. Many do so, and take their top hives or supers to market and get them back when the comb is all sold. I prefer the Californian plan. The extractors are too expensive.

..... I think the price of one of them is 8 dollars.

"The hives are all made very thick, an inch or 1½-inch stuff, the working holes 4 or 6 inches long. Some keep them in cellars all the winter, others keep them out; the latter is getting more into

vogue, as the removal entails much labour and cellars are too apt to be damp. Moths, large spiders, and the maple worm or "miller," are the great plagues, and oblige you to open your hives more frequently than you otherwise would. The black spider is a huge fellow, and soon makes havoc among your bees. I cannot handle my hives in the cool way many do—barehanded without dress or anything, but from practice they think nothing of it. I still keep to my bee-dress and indianrubber gloves.

"The profit of the business is very remunerating. Many clear 2000 or 3000 dollars a-year. It is better than farming if the season is good. I am only in a humble way, but I am preparing to enlarge my operations next season. There is nothing wonderful in the construction of any of their hives. Those who make a business of it do it in the cheapest and simplest way."

My friend sends me a diagram of the bars in use in his neighbourhood. They differ from ours only in having a projection of the side of the frame at bottom, meeting a circular projection at the side of each adjoining frame, to prevent the combs "rattling" or swaying backwards and forwards.—B. & W.

OUR LETTER BOX.

ARTIFICIAL BIRD'S EYES (J. H.).—Apply to Mr. Gardener, Naturalist, Oxford Street, London.

SCURFY FACE IN SPANISH FOWLS (J. C.).—It sometimes comes because the birds are out of health, and sometimes from an injury such as having been picked by the other birds. The treatment is to keep it moistened with sulphur ointment. In any case the suffering bird should be removed from the others, and the face frequently washed. While under treatment avoid any heating food.

SEX OF GOSSINGS (E. W. B.).—Your question is a difficult one to answer; there are many methods but difficult of description. In the gander appears a divided purse or egg-bag so to speak, whereas in the goose it is a single pouch. It is an old-fashioned plan in the fan country to shut up the Geese intended for selection for stock in a pigsty, and to throw in a little dog suddenly. The Geese retreat head up, the ganders advance hissing, head and neck extended.

CHLOROFORMING BEES.—"A. T." would be obliged by "H. C." stating how he placed the chloroform under the bees, and how long it requires to stupefy them.

REMOVING HIVES (A. B. C.).—Before you send your hives off by rail nail them to their boards so that they cannot slip any way on the journey. Send them singly and in their natural position, without packing of any description. At this season no ventilation is necessary during the transit. In spring and summer months ventilation through fly-proof is necessary. Of course the doors should be closed. Seed of *Melilotus leucantha* may not be mentioned in catalogues, but surely it can be had in good seed establishments. Write to one of the two good houses you have mentioned.

REMARKS.

- 2nd.—Close damp morning, very dull damp day; overcast at night.
3rd.—Fine spring-like morning, colder and dull in afternoon; wet at night.
4th.—Dark and gloomy, with rain at intervals all day.
5th.—Foggy and dark in the morning; very dull day, with slight rain occasionally.
6th.—Dull morning, brighter after 1 P.M., a little sunshine in afternoon; fine evening; slight rain about 11 P.M.
7th.—Very fine morning, rain commenced at 1.30 P.M., but only a few drops fell.
8th.—Dull morning, slight rain at times, with intermediate sunshine; clear and cold in evening.
Rather warmer than most weeks previous; especially close and muggy from the 2nd to the 6th.—G. J. SYMONS.

COVENT GARDEN MARKET.—JANUARY 9.

Our Market does not call for any remark beyond last week's report.

From observations taken near London during forty-three years, the average day temperature of the week is 43.5°; and its night temperature 31.6°.

KEEPING GRAPES—DEW.—No. 1.

R. D. THOMSON has demonstrated on page 34 that moisture in the borders is not powerfully inimical to late-hanging Grapes, for he has stated that the rainfall on the Vine borders at Drumlanrig amounted last year to the formidable total of 67½ inches! What do "dry" Grape-growers think of upwards of 5½ feet of water falling from the clouds, yet no wooden shutters being provided for sheltering the roots? It is tolerably clear either that the Vines at Drumlanrig receive too much water or those at many other places do not have enough, for certainly there are many gardens where the rainfall is not half that of Dumfriesshire, yet in the "dry" districts shutters are often deemed essential for protecting the Vine roots from "excessive" wet. The question, however, is one of drainage. If the water cannot percolate freely through the borders, leaving the soil sweet, 30 inches of rain become excessive; while, on the other hand, when the drainage is really efficient, more than twice that quantity of water is not only not injurious but beneficial. Much, also, probably depends on the nature of the soil.

At Drumlanrig the best evidence exists that the Vines do not receive too much water, or at least did exist when I had the privilege of inspecting the vineries, for better crops of Grapes I never saw. Not only were such varieties of Grapes that are ordinarily, and so often excellently cultivated in many gardens, in superior condition at Drumlanrig, but both Golden Champion and the Duke of Buccleuch were splendid. It is clear, therefore, that the extraordinary moisture referred to is not injurious to the growth of the Vines and the production of Grapes, and now we have evidence that it is not inimical to their preservation.

According to the testimony of Mr. Thomson Grapes keep better at Drumlanrig with its clouded skies and dripping atmosphere than they do in other districts where the rainfall is lighter and the atmosphere clearer. No one is more likely to be accurate in his statements than Mr. Thomson, and few have better opportunities for gaining experience, for his practice has been derived from a wide field extending from a point south of the fifty-second parallel of latitude in Hertfordshire to nearly the fifty-sixth in Haddingtonshire. But neither in north nor south was he able to keep Grapes with so little trouble as in the dull damp districts in which he is now so successfully working. Indeed, so easy is it to preserve Grapes amidst the woods and hills, and it may be fairly added water, of Nithsdale, that he is both surprised and perplexed at his own success, and cannot account for the singular immunity of the berries from decay. As there is a cause for every effect the duty is imposed upon gardeners to determine a "cause" for a circumstance which bears directly on a subject of considerable importance to them.

Although I have my own ideas of the chief causes that contribute to the sound and long-keeping properties of the Drumlanrig Grapes, I am not at all sanguine that I can convey them in a manner to be generally intelligible—not

because they are in any degree complex, for, on the contrary, they are extremely simple, but because I lack the faculty of that clear expression possessed by a David Thomson or a William Taylor. I will be satisfied, therefore, if I can give a "clue" for those and other cultivators to unravel and make plain, to substantiate or to demolish, according as there may be anything in the theory that I will try to advance as an important principle governing the keeping of Grapes.

It will not be inappropriate if I describe my idea as the "dew theory," because it is founded on the principle of the deposition of dew. According to the law which governs the phenomenon of dew, Grapes at Drumlanrig, when managed with that intelligence which all admit is exercised there, ought to keep exceptionally well. The circumstances which at the first glance might appear to be prejudicial to the good keeping of the fruit—I mean extreme moisture and a clouded sky—are, I think, in their very nature favourable when considered in connection with a system of management which I suspect is adopted in the Drumlanrig vineries.

A rainfall averaging 60 inches a-year presupposes an exceptionally clouded sky, a clouded sky an equable temperature, and an equable temperature an absence of dew. That is so on grass outside, why not, therefore, on Grapes inside? In order to render the matter as clear as possible it may be well to briefly refer to the principle of dew-formation. The cause of dew is cold. The temperature of the earth and bodies thereon fall by radiation and become colder than the atmosphere, the moisture of which is then condensed by and deposited on the cold surfaces, whether these are composed of grass, or wood, or iron, or Grapes. A clear air and sky promote the deposition of dew, and clouds prevent it by arresting radiation. The heaviest dews occur during a clear early morning when the surfaces have become much cooled, and especially when a clear morning succeeds a cloudy day. Dews are the most prevalent in spring and autumn, because then there is a greater difference of temperature between day and night. It is well to bear in mind those cardinal principles of dew-formation, because the subject has a direct and, as I believe, a very important influence on the keeping of Grapes; and it also affords a solution of the problem over which Mr. Thomson admits he is much puzzled.

When rains are prevalent and the nights and days are veiled by clouds for long periods, as must be the case in Dumfriesshire (where the vapours of the Atlantic which have accumulated in the atmosphere become condensed by the hills on the west coast of the island), the temperature must not only necessarily be more equable than in "bracing" districts where there are intermittent spells of clear and dull weather, but fire heat must be regularly employed in the vineries to maintain the requisite heat and to counteract the effects of the almost ever-falling rain. In this case the clouds outside and the fire heat inside prevent the Grapes becoming colder than the atmosphere, and consequently moisture, although it may be present in the air, cannot be condensed by and on the berries. It is the moisture that is precipitated on the Grapes on account of the bunches in a clear "bracing" district becoming occasionally or frequently colder than the air that is a prolific

source of decay; and sudden changes of temperature are at the root of the evil in nine cases of ten where Grapes will not keep. So far from the dull wet district of Drumlanrig being unfavourable for the keeping of Grapes, in my opinion it is, when fire heat is freely employed, specially favourable.

In a prevalence of clouds Nature has provided Mr. Thomson with a screen for arresting radiation, and this with the intelligent application of fire heat provides an equable temperature in the Drumlanrig vineries; a minimum quantity of dew then forms on the berries, and there is a corresponding minimum amount of decay. This is my solution of the mystery, and I ask that it be criticised—demolished if possible, for my only desire is that truth be established and that the keeping of Grapes may be better understood.—A NORTHERN GARDENER.

VEGETABLE CULTURE.

CHAP. III.—THE PEA.

THE Pea is a native of the Levant. The improved varieties now so commonly cultivated and so popular in our gardens originated from a very small fruiting kind which grows plentiful in a wild state there. It is within the remembrance of many when Peas were only cultivated in the gardens of the wealthy, but of late years every person possessing a garden devotes considerable space and much attention to their culture; and they are now regarded as one of the most important, because palatable and nutritious, of summer vegetables.

In all gardens Peas may be had more or less from the beginning of June until the middle or end of October. In exceptional instances they have been gathered both earlier and later than those dates, but the means taken to secure them could not be profitably adopted as a rule, and therefore need not be detailed here. In about sixteen weeks from the time the seed is sown in spring or summer the Peas are ready for gathering. For the earliest crop many are in the habit of sowing the seed in November of the previous year. In very mild localities this answers very well, but when the winter chanced to be severe we have gathered from the rows where the seed was sown in February just as early as from the November sowing. We have sown no Peas in autumn for some years, and we generally manage to gather Peas as early as our neighbours, and have full rows into the bargain.

According to the weather the earliest seed should be sown during the last week in January or the first week in February. The ground is rarely in a very suitable state for the seed germinating freely at that time, and it is a great advantage when this first sowing can be started into growth under glass. It does not require much heat to start them. A cold frame does it very well. The seed may be started into growth in two ways. One is to fill a number of 6 or 8-inch pots with rich soil, sow the seed about 2 inches from the top, and cover it with 1 inch of soil; the plants may then be placed in either a house or frame to start. They must not be watered much until they have grown about 3 inches high. Air should be gradually admitted until they will endure full exposure, after which they may be planted out.

They should be planted in a south border or in a sheltered position. The ground should be heavily manured and be dug deeply; and in planting them out of the pots it is only necessary to take a spade and make a deep notch in the ground where each row has to be placed, then turn them out of the pots and separate the growing Peas into little handfuls and plant each tuft 6 or 8 inches apart in the row. They suffer little through being transferred, and when it is very cold and windy at the time a few spruce branches on each side of the row protects them sufficiently. The other way of raising young plants is to take a number of strips of turf each about 4 inches wide, 3 inches thick, and 1 foot or 18 inches long. On the grassless side of each of these cut a notch $1\frac{1}{2}$ inch deep and 2 inches wide, lay them in rows on the surface of the border in any vinery, Peach house, or frame where the Peas are to be started into growth, then sow the seed thickly along the bottom of the notch and cover it with a sprinkling of fine soil. As soon as the seed germinates the roots run through the turf; and as soon as the plants are large enough to plant, the rows are notched in the open ground as before stated, and the strips of turves with the Peas growing in them are laid along the openings and the soil drawn round them without disturbing root or branch. This is the way we always raise and plant our early Peas, and we prefer it to any other.

At the same time as the seed is sown under cover a few rows should be put in in the open ground to give a succession.

Those sown in the open ground thus early should have the best position in the garden. A dry soil and sunny exposure is a great advantage to them. The ground should have been dug roughly some time previously to sowing. The rows of dwarf-growing kinds should be $2\frac{1}{2}$ or 3 feet apart; tall growers must be 6 or 8 feet. In preparing to sow the seed the drills should be drawn out straight, and 3 inches deep, with a draw hoe. One pint of seed is sufficient for a row 30 feet long. Peas sown during February and March may be termed early crops, and should have early positions. After the beginning of April the crops may be grown in any ordinary part of the garden. When the summer is excessively dry Peas do best in a moderately retentive soil, but in a wet season like 1877 an open soil suits them best, and it should not be less than 2 feet or 30 inches in depth. During the winter time the site on which Peas have to be grown should be roughly and deeply turned over; at the same time a liberal quantity of manure must be added, especially in the case of poor soil. The Peas may either all be grown together in one piece of ground, or a row may be placed here and there in the different quarters. We have tried them both ways, and we prefer keeping them all together, as when sown close to low-growing plants they shade and consequently injure them.

The quantity sown at one time must, of course, always be regulated by the demand, but to keep up a constant supply seed should be sown every twelve days, from March until the second or third week in July. The drills should be 3 or 4 inches deep, and the same in width. When the soil is very dry the bottom of the trench or drill should be well watered before sowing the seed, and after the soil has been covered over it the surface may be trodden with the feet. When the young plants are about 2 inches above the ground a little soil should be drawn to each side of the row with a draw hoe, and when they are 4 inches high a little more soil may be added and the stakes put in; these should be about a foot higher than the variety which they are to support is represented to grow, but the height any Pea attains depends on the character of the soil it is in. In poor dry soils it is a good plan in sowing summer Peas to dig out a trench as if for Celery, spread a quantity of manure at the bottom of it, dig it in, and then sow the seed. Dry weather has little effect on the crop when this is done, but in a wet season we have found them do worse in trenches than on the level ground. When the soil is good it is best to sow on the level, and if the plants should suffer from drought spread a layer of rich manure 18 inches wide and 2 inches deep along each side of the row. In dry times they are also much benefited by a good watering with liquid manure once a-week, which not only assists the pods in filling but has a strong tendency to prevent mildew, which is very liable to do mischief in dry weather. We have had some excellent Peas for years past on the ground where the Celery grew. After digging up the Celery the ground is simply levelled and the drill drawn above where the Celery trench was, and as the trenches are always heavily manured before planting the Celery the Peas grow most luxuriantly in them.

Amongst pests which attack Peas few are more troublesome than mice. If not looked after in time they frequently destroy the greater part of the seed. Wetting the Peas and then rolling them in red lead makes them distasteful to the mice. Chopping whins or furze small and spreading the pieces over the seed before covering with soil often prevents the mice reaching the Peas. At the same time traps should always be set near the row. Snails may be gathered with the hand, or the plants may be dusted with lime until they are 6 or 8 inches high. Birds sometimes pick the points out of the shoots while young, which stops their progress and spoils the crop. When the birds are very troublesome nets or wire guards become necessary to protect the rows. Under liberal culture caterpillars, weevils, and such-like pests give no trouble.

Of late years few vegetables have increased so rapidly in variety as Peas. Hardly a year passes without a number of new varieties being introduced, and while some prove to be improvements others are inferior to old sorts. Amongst the newer kinds Criterion (Standish) promises to be unusually good as a late Pea, and Harbinger (Laxton) is a promising early variety. Dr. Maclean (Turner) is the most productive of all the new Peas, and its other qualities are good. It is best suited for a midseason crop. The best Peas for general cultivation are:—

For Earliest Crops.—Sangster's No. 1, Sutton's Ringleader, Dickson's First and Best, William I. Dwarfs.—Little Gem and Tom Thumb.

For General Crops.—Hundredfold, Veitch's Perfection, Champion of England, Huntingdonian, Maclean's Wonderful, Carter's Little Wonder, and Laxton's Fillbasket.

For Late Crops.—Ne Plus Ultra, Maclean's Premier, British Queen, and Emperor of the Marrows.

Many more might be named in each class, but those mentioned are amongst the most serviceable for good cropping and ordinary use throughout the season.—A KITCHEN GARDENER.

BRUNSVIGIAS.

WOULD your correspondent, "H." (see page 10) kindly give us a little more succinct information as to his experience with this curious and difficult family of bulbs, as his treatment appears so different from that indicated by the habit of the plant?

The group of bulbs formerly included under *Brunsvigia* is now divided into—firstly, *Amarylises Josephinae* var. *striata*, *grandiflora*, *Banksiana*, *belladonna*, *blanda*. Secondly, *Brunsvigia multiflora*, *pumila*, *coccinea* (Kew), and some doubtful species: *marginata* seems never to have been clearly identified. Thirdly, *Boophana toxicaria*, *disticha*, *ciliaris*, *radula*, with some other uncertain species. Lastly, *Ammocharis falcata* and *coracina*.

Of these, the three first divisions comprise plants of the habit of the Guernsey and Belladonna Lilies, resting leafless, from May to September, when the flower is thrown up, followed shortly by the leaves, which make their growth through the winter and die off with the heat of early summer.

The last lot, *Ammocharis*, are summer growers, resting entirely leafless, through the winter.

I have never done much with the *Brunsvigias*, but have at one time or another cultivated all the types mentioned.

The huge *A. Josephinae* used to flower regularly every other year, rarely two years following. I have never seen *blanda*, *Banksiana*, or *grandiflora*, which seem to have gone out of cultivation. *B. multiflora* I flowered once only. I had a bulb under the name of *pumila*, but I think it was only a small specimen of *multiflora*. A plant in my collection from Kew, *coccinea*, seems distinct.

The remarkable section now called *Boophana* (Herbert) appear to be very shy flowerers. I think Mr. Leach of Clapham flowered one or two of them, and I understand from Mr. Boscawen that Mr. Tyerman has also lately succeeded with them in his fine southern climate.

Ammocharis falcata flowers freely if grown, as Herbert advises, as a greenhouse plant and removed into a strong heat about midsummer. *A. coracina*, as figured in the "Botanical Magazine," is, I think, a mere variety of *falcata*. My plants were very distinct from this both in the shape and colour of the inflorescence, while the foliage was that of *falcata*.

None of the family ever produced an offset in my garden except *A. Josephinae*, which after many years produced two and never thrived again; it, however, seeds freely.

The only kind that would appear likely to succeed, treated as recommended by "H.," would be *Ammocharis*.

I am away from home and my books, and write from old recollections, so I will ask your correspondent to excuse me if I have made any incorrect statements.—R. T. C., *Torquay*.

ARRANGEMENT OF PLANTS IN FLOWER BEDS.

"CONSTANT SUBSCRIBER" has a small flower garden consisting of two panels, each having an oval in the centre, with four corner beds and intersecting paths at the end of a terrace, close by the house, and therefore in a prominent position. It is required that the beds should be planted in summer with flowers raised from seed in spring, or that are hardy, and some few plants kept during winter in a greenhouse where space is limited and cannot be much encroached upon by "bedders"—a not unusual case, pointing to a very common want for which it is not difficult to find a remedy.

For the ovals our correspondent suggests a bordering of Ivy and a large Palm in the centre of each. As this garden is near the south coast no doubt a pair of *Chamærops Fortunei* would answer well and form a permanent feature of the garden. Failing the Palms I would fill the ovals with *Canna gigantea* major, a tall variety with bold green foliage, to which an outer circle of the dark purple-leaved *C. Warscewiczoides* would form a good contrast, lifting, thinning, and replanting them in fresh soil every third year. This plan will answer for the south, while in less favourable climates both the Palms and

Cannas must be lifted and taken indoors during winter, which is just what we wish to avoid in such small gardens as I am now writing for.

The corner beds are large, and if filled entirely with bright colours would be too dazzling. I would therefore treat them precisely as is done so successfully at Mount Edgcumbe in a flower garden in a very similar position, by making an uniform edging to all the beds of some dwarf compact-growing plant, with three or five rows of various-coloured bedding plants enclosing central groups of dwarf flowering shrubs planted thinly, with an intermixture of such hardy, tall-growing, bulbous-rooted plants as *Lilium* and *Gladiolus*, and an occasional choice *Phlox*, *Delphinium*, *Potentilla*, and other good perennials. The plan is not a common one, and those who have not seen it can hardly imagine how pleasing is the variety, relief, and brightness which it imparts to a design. Seen as I saw it in the most select position in the garden of a nobleman it impressed one as being so beautiful, so light and graceful, and so natural withal, as to be infinitely preferable to carpet bedding and all other popular styles, and when it is found to add to such merits the still more important one of economy in plants it must especially commend itself to amateurs and others of limited means and small houses.

Neatest of all edging plants are the *Sempervivums californicum* (calcareum) and *montanum*; both, moreover, are quite hardy, as is also the neat grey *Santolina incana*, the pretty golden *Arabis lucida*, and *Arabis alpina variegata*. Then, too, there are variegated *Vincas* and *Euonymuses*, especially the silvery-foliaged *E. radicans variegatus*—all hardy, and from seed an ample store of *Lobelia Erinus erecta* for blue, *L. Erinus alba* for white, *L. Erinus rosea* for rose, *Pyrethrum Golden Feather* for yellow, *Tropæolum Tom Thumb* for scarlet, *Tropæolum King Theodore* for dark velvety crimson, *Zinnias*, *Phlox Drummondii*, *Petunias*, and *Portulaccas* for all sorts of shades of colours from white to dark crimson, all of them continuing in full beauty almost as well as a *Geranium*; and then there are *Violas*. Perhaps the best of all, certainly as prolific of blossom and as durable as any, are *Corisandes*, pale primrose; *Crown Jewel*, rich yellow; *Mulberry*, deep mulberry; *Royal Blue*, bright blue; and *Vestal*, white.

Of dwarf flowering shrubs we have a host of beauties to choose from, such as *Berberis Darwinii*, *B. stenophylla*, *B. dulcis*, *B. Bealii*, *Mahonia aquifolium*, *Escallonia macrantha*, *Garrya elliptica*, *Cotoneaster Simonsii*, *Erica codonodes*, *E. mediterranea*, *Desfontainia spinosa*, *Daphne pontica*, *Hibiscus syriacus*, *Cytisus albus*, *Hydrangea paniculata*, *Pæonias*, *Spiræas*, *Kalmias*, *Azaleas*, and dwarf *Rhododendrons*.

I had almost forgotten *Dahlias*, of which we now have so many beautiful varieties, ranging from dwarf little bedders of a foot or two up to giants 6 feet high, and which might altogether fill the centres, but I certainly do not recommend this to the exclusion of shrubs.—EDWARD LUCKHURST.

MARKET APPLES—BARTON FREE-BEARER.

I AM at all times glad to be corrected when in error, but a correction is necessarily additionally welcome when it amounts to a confirmation. I stated on page 496 that I understood the late Mr. Pearson as having said that Duchess of Oldenburgh was a good market Apple, because of its hiding its bruises and turning out of hampers in good condition after a long railway journey. Mr. Alfred H. Pearson thinks there must be some mistake in this, yet he admits the "Russian" has "this good quality—that if stored away in hampers for four or five days the marks will almost entirely disappear, and the Apples will then invariably make more money at the market than any other sort at the same period of the year." That is really claiming more for the Apple than I intended conveying, but I do not suggest more than it merits. The late lamented owner of Chilwell certainly expressed a very favourable opinion of this valuable early Apple, and his son, I am pleased to see, confirms his late father's estimate and mine. I have grown the "Russian" and can speak to its good bearing property, its attractive appearance, its excellent quality, its tender skin, and its peculiarity in "hiding its bruises;" but I have not grown it for sale. Mr. Pearson's evidence on that point is, however, conclusive.

I did not allude to Keswick Codlin and Northern Greening because I felt their value as market Apples was sufficiently known and generally admitted.

Mr. Pearson on page 29 mentions the name of another Apple (Barton Free-Bearer) which he considers worthy of being

grown for market purposes, and he adduces good reason for his opinion; for when "fruit-gatherers of twenty years' experience never remember a variety failing," that is good testimony of its value. I never remember observing this Apple mentioned in the Journal before, and I suspect it is a local variety. I planted a tree of it nearly twenty years ago in an orchard where twenty other varieties were planted at the same time, and Barton "Free-Bearer" is now the largest tree of all, and has, I think, produced the least weight of fruit. It has now, however, commenced bearing, and judging from its appearance I have hopes that it will yet prove worthy of its name. I have never felt certain that this tree was correctly named; and since Mr. Pearson is so intimately acquainted with "Bartons," I shall esteem it a favour if he will state if the following outline description answers to the real Simon Pure:—Tree vigorous, forming a handsome yet somewhat open head without being spreading; fruit large and conical, resembling Alfriston in shape and size, yet slightly more conical than that fine Apple; skin more yellow than that of Alfriston; flesh also rather yellow and inclined to be spongy after the fruit has been gathered for some time; quality sweet rather than brisk. In use from November until March.

The tree has been long in attaining a free-bearing character, but now that it has commenced yielding fruit I believe it will be very valuable. In this respect it resembles Besspool, which I know is true, as it was obtained from Chilwell, "Bartons" having been procured from a less famous nursery.

Probably Lord Suffield has hitherto produced the greatest value of Apples since the trees were planted, closely followed, however, by Keswick Codlin, Duchess of Oldenburgh, and Hawthornden; but the fruit is apt to be blown off standard trees of Lord Suffield rather extensively. Hawthornden is much cankered, indeed almost worn-out; while "Bartons," Alfriston, Northern Greening, Blenheim Pippin, and Normanton Wonder are just arriving at their best. During the next ten years these good late kinds will probably yield a greater value of fruit than the earlier varieties that have hitherto been the more profitable. King of the Pippins has been the most profitable of the dessert varieties.—A NORTHERN GARDENER.

HOME-GROWN LILY OF THE VALLEY AND SPIRÆA.

DOUBTLESS many an amateur would like to have a few pots of Lily of the Valley in flower in winter if he could manage it without incurring the expense of buying imported roots. The following is a very good plan of bringing about such a result: About this time of the year, or indeed any time before growth commences, select some of the largest crowns from an old bed and tie them together with a piece of matting—half a dozen in a bunch—and plant the bunches a foot apart each way in common garden soil where they will have plenty of sun. During the growing season keep all straggling growths cut off with a hoe, and mulch or water if necessary. They will form good clumps for forcing in two years if large crowns were selected in the first place; less-sized crowns will take three years to come to perfection. I have never seen home-grown roots flower before Christmas so well as the imported crowns do, but they can be well done by the middle of January.

Spiræa japonica, or more correctly *Astilbe barbata*, can be grown as well in this country as in any other for forcing, and in my experience home-grown roots flower the earliest and best. They require to be planted out in rich garden soil early in the season before growth commences, and they may be lifted, potted, and placed in the forcing house in the autumn of the same year. Plants of this kept in pots through the summer are too much starved, and do not flower so early or so well as those which have been planted out.—WM. TAYLOR.

THE POTATO DISEASE.

I HAVE seen the remarks by "PERONOSPORA" on my articles "Speculations as to the Nature and Origin of the Potato Disease," but have unfortunately been prevented by domestic affliction from replying until now. I had some idea of adding to the title "With some Remarks as to New Diseases Affecting the Vine, &c.," but the Potato disease was after all the principal object I had in view. My critic appears to have been rather surprised at the articles and does not exactly see what I was aiming at. He evidently thinks I am capable of producing something better, or at all events of a more practical

nature. Those articles are only a part of my writings on the subject. I have a long essay nearly finished, in which I have approached the subject from the more practical side and duly followed what he considers the usual course in making use of the writings of others. I have not investigated the subject with the aid of the microscope, but have not hesitated to refer to the experience of others in the MS. But the microscope has not done much after all to enable us to get rid of the disease. Professor De Bary looked, with people to help him, for fifteen long years for the resting spores of the Potato fungus, but was never able to find them. Mr. Smith believes that he has. Admitting him to be right, still nobody knows how long they live or where they pass the winter.

With regard to diseases always being produced by infection my critic mistakes me. I did not mean to infer that all were so, but only some. The nature and origin of zymotic and other infectious diseases is, however, rather a difficult subject and not very profitable; besides, I have sufficient amusement at present with the Potato disease, *Oidium Tuckeri*, &c.

My critic is rather in doubt whether the disease had ever been attributed to insects, but it has; in fact it is difficult to say what it has not been ascribed to. Its origin has been attributed to insects, worms, and even snails. Mr. Henry Jenner, M.D., F.L.S.—a descendant of the immortal Jenner I suspect—wrote to a contemporary, "I suppose the cause may have originated from minute or animalcules flies spawning or depositing their eggs on diseased parts of the Potato haulm, which upon hatching the larvæ or young produced descend or creep down and enter into the Potatoes, particularly those inclined to or begun to rot or become diseased from damp or wet, &c."

Mr. A. Smee, F.R.S., published a wonderfully got-up book, which had the honour of being dedicated to the late Prince Albert, to prove that it was an insect, which he named the *Aphis vastator*, had done all the mischief. He believed that the first appearance of the disease in a healthy and previously undamaged plant was always subsequent to the visit of the destroyer, &c. These opinions were fairly met at the time, but I believe that Mr. Smee held them to the day of his death. I have no faith in the insect theories myself, and insects are not referred to in the "Speculations" with that idea; it was merely to show that new diseases, so called, had suddenly appeared and caused great loss among the Vines, and that the origin of these was apparently shrouded in mystery, and might have still remained so if they had been sufficiently minute to escape observation, whilst at the same time their presence here might be accounted for in a rational manner, and that they all of them, including the Potato disease, seemed to point to one country as the source from which they were derived.

With regard to spontaneous generation "PERONOSPORA" thinks me in error in attributing to Professor Tyndall a belief in this. What I said was, Professor Tyndall would have to try those experiments a long time before he convinced me. I have not the pleasure of his acquaintance and do not know what his private views are, but have seen reports of his investigations, and unless I am very much mistaken they led him at one time to be inclined to believe in it; in fact it was only a week or so ago that he published his final conclusions against it. How did I arrive at my conclusions? Did I carry out a series of experiments? No, I did not make any; I am quite satisfied with the investigations of Professor Tyndall, they could not have been in better hands. I did not believe in it, because it is contrary to common sense for something to come out of nothing; besides, I have read of experiments by others, and seen often, where spontaneous generation was brought in aid to account for certain phenomena, they were afterwards accounted for in a more rational manner.

"PERONOSPORA" does not care very much for the general public. Now I do. It is for them I write, and I want every reader of this Journal to have a fair knowledge of the Potato disease if they have not already; so that we shall no longer have letters written ascribing its origin to degeneracy of the tuber, injury by storing, &c., things which my critic dismisses in a body as no longer worthy of consideration.

With regard to origin, there are various ways of looking at the subject. One is, some people speak about the origin when they mean the cause of their little patch of Potatoes being attacked by the disease; another is, what was the cause of the first British Potato being attacked? These points are disposed of in the essay. The third and most interesting is the one referred to in the "Speculations." From the northern exten-

sion of certain birds, animals, and plants I was led to suppose that the fungus might also have extended northward, so that the disease might after all have existed amongst the wild plants of the *Solanum* family in the neighbourhood of Colorado; but this was theory only. Whether the facts will bear out the theory I am endeavouring to ascertain.—*AMATEUR, Cirencester.*

ROSE SHOWING.

I AM an amateur growing a few Roses, but desirous of growing more and becoming an exhibitor. I therefore want to know what Roses to buy. The Rose election list tells me what sorts, but I am in doubt as to how many sorts and how many plants of each to buy, and to my surprise the Rose Journal only increases my perplexity.

I first of all turn to one of "WYLD SAVAGE's" articles, and as I have but a slender purse I am horrified to read that an intending exhibitor "will require at least twenty of each sort;" but on coming to another article by the same gentleman I find that "a man who wishes to show twenty-four trebles well ought to have about fifty good plants of thirty sorts," or one plant and a half instead of twenty of each. Then comes Mr. Curtis, who says, "Every amateur who exhibits in the class for forty-eight must grow at least seventy-two of the best exhibition flowers to meet the vicissitudes of our seasons. . . . Amateurs should grow nearly double the number of varieties they intend to exhibit, to be ready for any season." Lastly, Mr. Bensted says I should have a different number of each of the first twenty-four sorts in the election list, and begins with one dozen of Baronne de Rothschild, and ends with twelve, eighteen, and twenty-five dozen each of Louis Van Houtte, Emilie Hausburg, and Horace Vernet.

Now, which piece of advice am I to follow? The question in my mind is, If I procure three plants each of the first fifteen sorts in the election list, shall I be safe for showing twelve single trusses at two or three of the metropolitan shows next summer? By inserting this in the Rose Journal I have no doubt you would elicit information that would be of great service to me and many other small growers.

There is one other matter connected with Rose-showing that I am tempted to say a word about. In an article about the show at the Aquarium "WYLD SAVAGE" wrote—"I was just saying to my man, Wire this Rose, will you?" &c.; and in last week's number Mr. Peach in his interesting article speaks of "heads of Tea Roses well wired to bits of stick," &c. Now it seems to me that this is very like cheating, and ought to disqualify a stand, for it enables a man who knows how to do it to make his Roses appear better than they are, and so another man whose Roses are as good or better, but who exhibits them as cut from the tree, is passed over in favour of the artificially improved blooms. This ought not to be.—*A LOVER OF ROSE SHOWS.*

WATERCRESS IN FRAMES.

SWEET crisp Watercress is always welcome on the breakfast table during the winter months, therefore a few remarks on its successful cultivation will not be inopportune. I have been gathering at the rate of three bunches of useful Cress daily from a two-light frame for the last three months, and could now gather twenty or more bunches if needed. I find that Watercress is esteemed more than all other salads at this time of the year, and fortunately none of them can be produced more easily.

About one-third of the frame mentioned is filled with plants in 24-sized pots, which are placed in teakale-pot lids turned upside down; a little shingle is placed in the bottom of the pans, which are sunk in ashes to keep them firm, and they are then filled with water (rain water I find the best), which is replenished as it wastes. A second batch was grown in 48-sized pots, which were placed in some old evaporating troughs, which answered admirably. Shingle was placed in the troughs to stand the pots upon, and the troughs were filled with water as before mentioned. The remaining portion of the frame was filled by pricking Cress out in soil, which was merely placed upon the ashes.

I found the 24-pots the most productive, although the Cress from the 48's was the first ready for gathering, being a week or ten days earlier than that pricked out in the frame; but the latter forms a good succession and is more productive than the former. I shall certainly adopt the planting-out system more extensively next autumn, for I believe the Cress to be

better flavoured than that grown in pots. I do not suppose that this system would answer in the summer months, as it would be difficult to provide enough moisture to give satisfaction.

The position of the frame is on the north side of a Thorn hedge about 4 feet 6 inches in height, which increases in height as the summer advances, which is just what is wanted for affording shade.

The soil I employ for pricking out the Cress in the open frame is composed of very strong loam with a small admixture of decayed manure pressed rather firmly to hold the water as long as possible. For pots I use a compost made lighter by adding decayed leaf soil and a little river sand. The worst enemy I have is the slug; I, however, manage to keep them pretty well at bay by placing a little salt round the base of the frame outside.

I find the browning of the Cresses depends chiefly upon the amount of air and light given during the growing period. In favourable weather the lights are tilted about an inch at the back, which is not allowed more than four hours in the middle of the day during the winter. As the temperature increases more air is admitted after the cuttings are established, but the frame is closed early in the afternoon, giving a thorough watering overhead. Those of your readers who have not tried the cultivation of Watercress under glass would do well to give it a trial and let us know with what results through the Journal.—*J. P.*

HINTS ON GROWING VEGETABLES.

MY garden owes much, very much, to our Journal, and it is in the hope of repaying to others some of the pleasure and profit I derive from the perusal of that eagerly-looked-for item of Friday's post that I venture to send the following "hints from experience," which I have found valuable in past seasons. First let me say (what I wish all, even Messrs. Luckhurst and Abbey, would state at the top of their papers) that the soil is a stiff clay, the land being well drained but very exposed. I have it dug with plenty of old stable manure as soon as ever the crops are off, and before the winter rains make working impossible, and let it lie rough till spring. Secondly, I never care to sow anything before the last week in March or the first fortnight in April, and when I do I attend to the following points, which I find very important.

Peas.—Soak the seed for four or five hours in milkwarm water. If the ground be rough work up a strip a foot broad and the length required for the row to a depth of 2 inches with a spade, as if chopping meat, until it is quite fine; then remove 1½ inch of the soil all down the row for a spade's width (7 or 8 inches). Work up the bottom 1 inch as before, and sow your Peas all over this broad trench 1½ to 2 inches apart. Cover with the soil which was removed and put on wire protectors, banking up their sides with soil. N.B.—Do not sow after June 10th. I grow 100 yards of Peas every year, and find this the surest and best way.

Celery.—Sow in April in fine soil. Plant out during the last week in June or early in July in trenches 1 foot wide, plants 7 inches apart; place pea wires across the trenches, and cover with mats till established. Fill in the trench during August, and about 20th September wrap the plants with brown paper secured by a strip of bast in a single knot. Earth-up to within 6 inches of the top at once, and you will have a first-rate crop. The trenches should be a foot deep with 4 inches of good manure at the bottom, and just a sprinkling of earth to keep it moist.

Strawberries.—Take runners off August 10th, or as soon as ready. Plant in a nursery bed. Choose a piece of ground which has been cropped with Potatoes for your bed. Manure it well, and in the beginning of October put in your plants. Let the rows be 2 feet apart and the plants 1 foot in the rows. When the bloom is set mulch with clean straw, and in the autumn cut off the leaves, except half a dozen at the top, and dig in a good dressing of well-decayed manure. The first season the crop will be fine but not large, the second year Black Prince will give a quart per plant, and British Queen berries, which cannot be beaten for size and quality, 45 quarts per hundred plants.—*A YORKSHIRE AMATEUR.*

ZINC LABELS.

I QUITE agree with "AMATEUR" in what he said last week about zinc labels. Many years ago—more than thirty—I planted an orchard of pyramid trees, all of which I named with zinc labels suspended by copper wire. In little more than a year

I saw them begin dropping so rapidly that there was a risk of my losing the names of the trees altogether. As the labels were made of long narrow strips of zinc I bent them round the side branches of the tree like a ring, allowing the ends to touch by their edges, so that when the branch grew so much as to close up the ring, the latter continued to expand with the size of the branch, and these labels are on the trees now. The cause of labels that are attached by copper wire so soon dropping is the result of galvanic action set up between the two metals, and the zinc is decomposed. Zinc by itself has no injurious effect on the trees.

The names were written on the labels with metallic ink, which is transparent when used but immediately turns black. The names are now as black and distinct as they were the first year after they were written, which, to be precise, is thirty-two years ago.—A COUNTRY DOCTOR.

REIGATE CASTLE.

AMONGST the many who whirl past Reigate by the Brighton express, or plod past it much more leisurely by the loop line to Reading, perhaps few are aware of its interesting Castle, placed at the head of the noble Holmesdale valley—"Holmesdale, never won, never shall," as the men of Kent assert of it. The position before gunpowder must have been strong and important; now it is completely commanded by hills on either side. This was one of the many castles belonging to the first Earl of Surrey, better known as De la Warrene, who married H.R.H. Gundrada, daughter of William the Conqueror, whose remains repose at Lewes. "To earth a Martha and to heaven a Mary," as her Latin epitaph still tells us. These great people and their powerful descendants appear to have owned a large portion of the county. Their armorial bearings yet survive in certain places of much less dignity: blue checker signs to wit. However, they are the rightful emblazonings now of Surrey, according to the old antiquarian legend:—

"The true arms of Surrey to have and to hold
Are the famed Warren checkers of blue and of gold."

The Castle now is one of the most charming spots imaginable. In the very centre of the Earl's good town, only a step out of the High Street, is a series of well planted winding walks with grassy slopes, and, on the centre of what was the tall keep once is now a model town Rose garden, evidently the most attractive feature of all.

Through the great liberality of Earl Somers, Reigate's Earl of the nineteenth century, Holm Castle, as it used to be, has been made over to the citizens, and is now heavily garrisoned with infantry of another kind, delighting in those formidable war chariots—perambulators! It is a paradise of nursemaids and their charges, and at certain hours young Reigate in general. On the Earl, some years ago, making over the site to the town authorities, the grounds were tastily laid out. They are kept up at public expense, and most liberally thrown open all day long to the public. On the top of the keep is a wide grass platform with exquisite panoramic views; underneath is the Baron's Cave. This is excavated out of the famous white sand—"Reigate white sand, none such in England." In this large and safe retreat the barons of England are said to have premeditated the Magna Charta, to which their false monarch shortly after affixed his reluctant signature at Runnymede. Murray says this could not have been so, for that Earl Warren was a friend of the king's. People, however, who spoil legends should never be credited.

I apprehend the Lady Gundrada would not be displeased if she could revisit her Castle. Certainly she would think there had been an advance made in Roses. In that delightful circular Rose border on the top of the keep all the new Roses are to be found, and, what is perhaps better still in our rapid days, all the best of the old Roses. All honour to Reigate's Corporation and their efficient representative in charge of the Castle.

A less attractive epitaph than that of H.R.H. was till lately to be seen in the neighbouring cemetery. It has, at least, the merit of plain speaking:—

"Clerk of this parish I was in sooth,
By trade a tailor, by name John Tooth.
Faults I had many, you who have none
Are justly entitled to cast the first stone."

—A. C.

ÆSCHYNANTHUS SPLENDIDUS.

ONE of the brightest flowers in my stove and one of the most admired in summer is *Æschynanthus splendidus*. This genus

of plants appears to be somewhat neglected now, yet some of the species are very valuable, especially by affording cut flowers for vases for room-decoration. The plants are of easy culture; brisk heat, a very rough compost, and copious supplies of water being the chief points to be attended to, to ensure success. *Æ. splendidus*, I am told, is not a species but a variety. Can you inform me if this is correct? It is of more upright growth than any other of the family that I have grown. I consider it very beautiful, and I value it the more because it is not by any means common. It is because I think this plant is deserving of more extended cultivation that I draw attention to it. The colour of the flower is bright orange-scarlet deepening to vermilion, with purplish crimson lobes.—A. R.

Fig. 8.—*Æschynanthus splendidus*.

[*Æschynanthus splendidus* was raised several years ago by Messrs. Lucombe, Pince, & Co., of Exeter, by their having crossed *Æ. speciosus* with *Æ. grandiflorus*. It is one of the most free and bright of the genus.—EDS.]

GLAZING WITHOUT LAPS OR PUTTY.

ABOUT four years ago I erected a house 50 by 11 feet principally for bedding plants, glazing without laps or putty. It is everything I could wish. There is no drip, and if a pane is broken another can be substituted in two minutes in any weather. I got the idea from seeing a house at Messrs. Smith's of Dulwich, and have made a few apparently trifling but really important alterations, one of the principal in providing for water getting into the groove as mentioned by Mr. Laycock. I have every confidence in recommending this system if carried out properly. I do not care to have the panes cut to a nicety at the ends, as it is not necessary to prevent water coming in, and a slight opening allows ventilation. When painting is necessary my own men take out one or two screws in each row, and, after giving two coats of paint, replace the glass very quickly. The advantages are—there is no drip, no dirt between the laps, consequently more light, always looks clean, and easily repaired in any weather. I shall be happy to show

my house to anyone who thinks it worth while to come and see it. It would not be safe for any gentleman to put a house up unless he either saw or obtained a working plan before doing so.

In reply to J. R. Cooper, the top pane is pushed into a groove in the roof-tree to prevent water getting in there, and wedged with indiarubber so that wind cannot affect it. Two indiarubber rings are placed on each side of the panes, and a brass screw passes through into the rafter. The glass is prevented from slipping down by a screw and ring at the bottom.—J. CARTER, *Keighley*.

NOTES ON CHRYSANTHEMUMS.

AMONGST the numerous varieties of Japanese Chrysanthemums now in cultivation are to be found some of the earliest to bloom of the whole race, as well as some of the very latest, and with a good collection a longer period of bloom can be maintained than with the incurved varieties alone.

For the embellishment of vases and for house adornment the Japanese section possess this advantage over the more formal incurved varieties—that they can be cut with a longer foot-stalk, and have a lightness and gracefulness of their own, and, as a rule, carry a greater proportion of good flowers.

The incurved varieties are undoubtedly the florist's type of this flower, and when well grown are compact, even, and beautiful rounded balls, while the Japanese are grotesque, loose, and wanting in that solidity which is characteristic of the incurved type. Still, how beautiful are the trio of Mrs. G. Rundle, George Glenny, and Mrs. Dixon! so beautiful that they and others cannot be dispensed with, for they make our conservatories gay for several weeks during the darkest season of the year. As the incurved varieties have been grown so long and have received from their popularity the greatest encouragement, my intention is to note more fully the best of the Japanese varieties; for though they are yearly gaining favour, they have not as yet received the attention they deserve, and in some districts are little known.

We have recently had some valuable additions to this section introduced from the Continent, two of which will soon become conspicuous in every collection—notably, *Fulton* and *Fulgore*. *Fulton* is of the most intense bright golden yellow colour, even a brighter yellow than the beautiful and well-known *Jardin des Plantes*; it has long rounded petals of good substance, and is altogether a very attractive variety. *Fulgore* is one of the freest to bloom; it is very large and full, with long twisted petals of a fine rosy-purple colour, and very distinct. *Laciniatum* will, I think, prove another valuable variety; it is medium-sized, but fringed like a *Pink*, and of a whitish or bluish tint, and may be employed in the making of bouquets, &c. *La Nymph* possesses qualities new to this section; its habit is so dwarf and it is so free in flowering that plants not more than 18 inches in height and carrying quite a dozen blooms can be grown in 32-sized pots. Its colour is delicate peach. It is very valuable for growing in quantity for front lines in conservatory decoration.

There are several other new varieties that I have not had the opportunity of proving, and amongst them is *Peter the Great*. A good flower of this variety was shown by the Secretary of the Lambeth Amateur Society, whose good collection is grown in the very heart of London. At *Walton*, Japanese varieties were considerably above the average, one exhibitor staging extraordinary examples of *Yellow Dragon*. At *Kington-on-Thames* the increase in the numbers of exhibitors of this section was very noticeable, and new varieties were staged in great excellence. *Bronze Dragon* and *Jane Salter*, two varieties not sufficiently known, as staged by Mr. Hinnell were indeed grand. I was unable to visit the Chrysanthemum Show held at the Aquarium, where I am informed the Japanese varieties were prominent; but at *Dartford*, *Croydon*, and *Brixton* Shows they were shown very sparingly, confirming the opinion I have already expressed, that in many localities they do not receive that attention which they deserve.

James Salter, a very pleasing lilac, *Elaine*, pure white, *Fair Maid of Guernsey*, pure white with long ribbon-shaped petals, and *Fulgore* are amongst the first to bloom. The two former were fully expanded in most places this season during the last week in October. Some years they can be had two or three weeks earlier; and on Wednesday, January 2nd, I cut a box of very fair examples of *Baronne de Prailly*, rose colour changing to pink, *The Mikado*, orange yellow, *The Sultan*, rosy lilac, *Meg Merrilees*, sulphur white, and *Grandiflora*, a very late

golden yellow. Thus for a period of eleven weeks have these dull-weather flowers helped to make us gay. What other flowers can supply their place with the corresponding amount of convenience and trouble required? None. Their culture is of the simplest, and may be summed-up in one word—Attention: Attention to watering, attention to potting them into their blooming pots without allowing them to starve in their small state, attention to prevent the wind from snapping them off, and attention in placing them under shelter from autumnal frost and rains.

Aurantium, *Bismarck*, *Chang*, *Gloire de Toulouse*, *Oracle*, *The Daimio*, *Magnum Bonum*, *Garnet*, *Nuit d'Hiver*, *Red Dragon*, and *Wizard* are sorts worth adding to every collection where Japanese varieties are desired.

In concluding my "Notes" allow me to ask, Are the sections of Chrysanthemums sufficiently defined, and what should be the distinctive standards of Japanese, incurved, and reflexed? Many of our so-called Japanese varieties bear an affinity to other sections. Does not *Elaine*, although she is so chaste and beautiful, resemble a large reflexed flower? and is not *Mons. Lucien Barthère* with its golden velvety petals a real reflexed flower? while *Triomphe du Nord*, which is described in almost every catalogue as reflexed, is evidently a real Japanese flower.—J. W. MOORMAN.

ROYAL HORTICULTURAL SOCIETY.

JANUARY 15TH.

A SINGULARLY mild morning enabled tender plants and flowers being safely removed from their homes, consequently the first meeting of the year was an extremely attractive one. There was also a very full attendance of horticulturists, and the members of the Fruit and Floral Committees assembled with scarcely any absentees. The tables surrounding the Council-room were well occupied by collections of plants from the establishments of Messrs. Veitch, Williams, Bull, Wills, &c. Excellent Grapes came from *Coombe Abbey* and *Lockinge*, Apples from *Langley*, Nuts from *Chiswick*, and cut flowers (*Zonal Pelargoniums*) from *Swanley*, and *Poinsettias* from *Heckfield*.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P., in the chair. Mr. Joshua Atkins, gardener to Col. Loyd Lindsay, *Lockinge Park*, Wantage, sent four very fine bunches of *Muscate of Alexandria* Grapes, evidently from the same house as those that were exhibited at a former meeting. They were, as a natural consequence, somewhat shrivelled, but in fine condition, and a cultural commendation was awarded, the silver Banksian medal having been given at the former meeting. Mr. Miller, The Gardens, *Coombe Abbey*, exhibited six large and handsome bunches of *Gros Guillaume* Grapes, the aggregate weight of which was 26 lbs. They were well coloured and of excellent flavour. Mr. Miller was awarded a special vote of thanks. Mr. Miller also sent a fine collection of Citrons and Oranges grown on the back wall of a vinery, to which a letter of thanks was awarded. A fine collection of ten varieties of dessert Oranges was sent by Messrs. Rivers and Son of *Sawbridgeworth*: *Bittercourt Orange*, *Long Orange*, *St. Michael's*, *Maltese*, *Oval Blood*, *White Orange*, *Prata* or *Silver Orange*, *Thin-rinded St. Michael's*, *Tangerine*, and *Bijou Lemon*. A first-class certificate was awarded to *Long Orange*, and a cultural commendation for the whole collection. Mr. Ollerhead, gardener to Sir Henry Peek, Bart., sent a good fruit of *Queen Pine*. Mr. Wood of *Newport*, Isle of Wight, sent a seedling Apple, which was out of condition. Mr. W. Hackin, seedsman, Taunton, sent a seedling Apple closely resembling *Blenheim*, and if distinct not superior to that variety. Mr. R. H. Tromp of *Clifton*, Bristol, sent fruit of a *Maltese Apple*, which is of a long narrow conical shape, perfectly white, and with a sweet tender flesh. It is wholly unknown in this country, and would probably not succeed in this climate. Rev. George Kemp of *Sevenoaks* exhibited fruit of *Beurré de Jonghe Pear* in excellent condition and fine flavour. It is a good bearer, and deserves to be cultivated in every garden. A letter of thanks was awarded to Mr. Kemp. Mrs. Hewson of *Redhill* sent a seedling Potato, raised from seed of *Paterson's Victoria*, which was not an improvement. Mr. L. Killick of *Langley* sent a fine collection of fifteen varieties of Apples grown in his orchard at *Langley*, which were remarkable for their fine growth, colour, and flavour, and a special vote of thanks was awarded.

FLORAL COMMITTEE.—Dr. Denny in the chair. Messrs. Veitch and Sons staged a remarkably bright collection of Orchids. Conspicuous was a plant of *Angraecum sesquipedale* with six flowers. *Cattleya Triana* was also very effective. Amongst the smaller plants a very fine example of the pure white *Masdevallia tovarensis* attracted much attention. *Lælia alba* and *L. alba rosea*, *Odontoglossum cirrhozum* in several fine varieties, also *O. Andersonianum*, *Oncidium Forbesi*, *Lælia flammula*, *Saccolabium giganteum*, several *Cypripediums*, the curious *Masdevallia polysticta*, the brilliant *Sophranitis grandiflora*, and the chaste *Pleione*

humilis completed the group. In addition Messrs. Veitch exhibited several plants of *Rhododendron Early Gem*, which is so valuable for early decoration, the dwarf plants being quite covered with pale lavender-coloured flowers. They also staged *Primulas*, a few *Palms*, and about fifty plants of densely-bloomed *Cyclamens*. A vote of thanks was awarded.

Next came an attractively arranged group from Mr. Wills. The groundwork was composed of Maidenhair Ferns with a fringe of *Lycopodiums*. The flowering plants comprised small plants of *Phalenopsis Schilleriana* and *amabilis*, *Odontoglossum Alexandræ* with very fine spikes, *Lælia anceps*, and *Cyclamens*. The taller plants were represented by *Palms* and one or two *Dracænas*. A vote of thanks was awarded.

Mr. B. S. Williams staged effective plants of *Cypripedium* insignis, a fine example of *Sarracenia Drummondii* with fifteen pitchers, also well-grown plants of *S. purpurea major*, *Cypripedium venustum*, *Dendrobium moniliforme*, *Cattleya Trianae*, and *Cyclamens*; also a dozen plants of *Solanum Capsicastrum* var., the plants being upright in growth, having dark foliage and fine berries—a capital strain. In addition to his miscellaneous collection, for which a vote of thanks was given, Mr. Williams was awarded a first-class certificate for a very elegant Fern, *Microlepia hirta cristata*. The fronds are light green, gracefully arched, all the points being divided and crested. It will prove an elegant basket Fern, for it is evidently of free growth and will flourish in an intermediate house. A similar award was made for *Dendrobium superbiens*, a distinct and beautiful *Dendrobium* of strong growth. The prevailing colour of the flowers is purple-lake, the petals being darker than the sepals and also much longer, and the whole elegantly reflexed. The growth of the plant is upright, and it evidently flowers freely, the peduncles having about a dozen flowers which are about an inch in diameter. Mr. Williams had a botanical commendation for a curious terrestrial Orchid, *Pterostylis Baptistii*, the spike being surmounted with a solitary green flower with whitish throat. It is a great curiosity and in outline bears some resemblance to a *Masdevallia*.

In contrast with the flowers a collection of *Cycadaceous* plants from Mr. William Bull occupied the opposite side of the room. These plants are both stately and elegant, and their beauty is of a lasting character. They are admirably adapted for various purposes of decoration. First-class certificates were awarded for *Zamia corrugata*, a stately plant with tall fronds and bright green leathery leaves a foot long and 3 to 4 inches broad, the surfaces being singularly ribbed or corrugated; also to *Z. lucida*, a plant of dwarfer growth, the leaves being about 6 inches long and 1½ broad. The remainder of this collection consisted of *Encephalartos villosus amplius*, *E. cycadæifolius*, *E. Ghellinckii*, *E. Vroomii*, *E. Hildebrandii*, *E. horridus multiflorus*; *Zamia mexicana*, *Z. Lindeni*, *Z. Roezli*; *Cycas Armstrongii*, *Bowenia spectabilis serrulata*, *Ceratozamia nobilis*, and *Catakidzamia Hopei*—an unique collection, which merited the vote of thanks awarded.

Mr. Ollerhead, gardener to Sir H. Peek, Bart., M.P., Wimbledon House, exhibited the finest variety that has hitherto been seen of *Odontoglossum cirrhosum*. The flowers are large with broad pure white petals and sepals, the spots being very large and of the richest maroon colour. It is extremely beautiful, indeed too much cannot be said in its praise. We congratulate a good gardener on the possession of such a valuable plant. It is the first plant that flowered out of a dozen obtained from Messrs. Veitch, and further varieties will be looked for of this free and beautiful Orchid. A vote of thanks was awarded to Mr. Ollerhead.

Mr. Heims, gardener to F. A. Philbrick, Esq., Avenue Road, Regent's Park, exhibited *Cypripedium Boxalli*; Mr. Tong, gardener to J. S. Law, Esq., Enfield Chase, *Oncidium carthagenense* var. *Klotzschianum*; Mr. Dean, *Crocus Imperati*; and Mr. Spary, *Queen's Graperies*, Brighton, fringed *Primulas*.

The cut flowers of *Zonal Pelargoniums* exhibited by Mr. Cannell, Swanley, were remarkable by their size, freshness, and beauty; indeed, finer trusses were never seen at any season. The varieties were *The Shah*, *Lizzie Brooks*, *Louisa*, *Kleon*, *Mrs. Leavers*, *Remus*, *Laura Strahan*, *Dora Charlton*, *Jean d'Arc*, *Dazzler*, *E. Davis*, and *Lord Gifford*. A vote of thanks was worthily awarded for them. A similar mark of recognition was made to Mr. Wildsmith, gardener to Viscount Eversley, Heckfield Place, for six heads of *Poinsettias*, which were not more noticeable for their size and the great number of bracts than for their brilliant colour and the rich dark green foliage. They were excellent examples of good cultivation.

From the Society's gardens at Chiswick came plants of *Senecio Ghiesbreghtii*, which attracted considerable attention. They were about a foot high, with large *Solanum*-like leaves a foot long and 7 or 8 inches in diameter, each plant having a head more than a foot across of bright orange *Grouse*-like flowers. When viewed from a distance these plants resembled gigantic *Cockscombs*.

APPLES AND APPLE TREES.

In the Journal for the 3rd inst. Apple trees are mentioned as ornaments in the shrubbery. I wish the suggestion was

carried out; they would not only be ornamental but useful both for our consumption and for the fowls of the air, and would be the means of saving much of our garden fruit from the feathered race. The idea about the planting of more fruit trees is not new. I contend, and have long contended, that where we have one fruit tree planted we ought to have one hundred.

I have in years gone by planted different kinds of fruit trees in open spaces in the shrubbery, and intend to plant more. I wait not to purchase but to work my own in the best way I can.

Your correspondent names an Apple that is far too little known or cultivated. When a youth in a nobleman's garden we had the *Gravenstein* Apple trained on a south wall. The situation was not favourable to the cultivation of Apples, the soil and subsoil being a wet heavy clay, but with draining and the best treatment we could devise we were well repaid with fine fruit of this valuable Apple for dessert from the end of September to November, and though forty years have passed I have not forgotten the estimation they were held in. I incline to doubt whether at that season there is an Apple that can compete with the *Gravenstein*. I have also seen it grown as standards in other situations, attaining to a full-sized tree yielding moderate crops. It cannot be called a free bearer, but is of good growth and habit, seeming to do best on the limestone. It ought to be more grown than it is at present.

It is not easy to make selections of Apples among so many. According to my own estimation *Nelson Codlin* or *Backhouse's Nelson* is one of the very best Apples in cultivation. It possesses all the properties that constitute a first-rate Apple, and it has one more, for it happens to be in possession of so much pleasant saccharine matter that the eater usually can dispense with the sugar basin when he has this Apple in a tart. It is also useful for dessert, and is a capital baker. I have had it fine till March. It is large, of good appearance, tree of moderate size and an abundant bearer.—*PYRUS MALUS*.

HOLME LACY.—No. 3.

THE SEAT OF SIR HENRY SCUDAMORE STANHOPE, BART.

BETWEEN the pleasure grounds, which have been described, and the kitchen garden to be alluded to, there is a small strip of ornamental ground. This is separated from the pleasure ground proper by a bank of common Laurels, from the summit of which at intervals rise young weeping Birches, their gracefulness apparently being enhanced by the close mass of Laurels from which they spring. It is a pleasing termination to singularly attractive grounds. Behind the Laurels is a Yew hedge, which constitutes the eastern boundary of the enclosure mentioned, of which the garden wall forms the western extremity. Through this strip a curved walk with flower borders on either side and luxuriant standard Roses conducts to the kitchen garden. Behind the borders are lawns, which contain amongst other ornaments a handsome *Araucaria* and noteworthy specimens of those miniature Conifers *Pinus pygmaea* and *Abies Clanbrasiliana*; also a fine clump of *Pampas Grass* and a good example of the distinct deciduous tree *Catalpa syriacifolia*. Yet another tree here demands notice, not because it is rare, but because it is common and affords an useful lesson. It is a fine old Yew, the ground of which beneath its dense shade might have been bare had it not been for that most valuable of evergreen shade-enduring plants—the small English Ivy. This completely covers the ground, and is permitted to ascend the stem of the Yew to the height of a few feet, producing a very ornamental effect and telling passers-by, as plain as Ivy can tell, how valuable it is for covering the ground under trees, and how inexcusable are bare unsightly patches on lawns or banks, where a refreshing covering of green would be so much more enjoyable. However dense the shade may be, or dry and poor the soil, this Ivy will flourish and form a pleasing evergreen carpet, a fact that is worth being repeated that it may be the better remembered.

Pass we now to another feature of Holme Lacy. We are in the kitchen garden. It is a walled enclosure of two acres. The south wall, or a good portion of it, is covered with glass—four vineries and a Peach house: the east wall with Apricots, the west with Pears, and the north with Cherries. By the sides of the walks are very old herbaceous flower borders separated from the vegetable quarters by espalier fruit trees. There are also some established "ropes" of horizontal cordon trees, which bear good crops of very fine fruit. When one tree reached the stem of the next it was grafted on to it, and

eventually the stems of every alternate tree were cut away. The result of this was that the growth of the cordon was less luxuriant, while the fruit was finer than before. The soil is evidently good for fruit trees, Strawberries, and vegetables, all of which were growing with great freedom.

The chief range of glass is in keeping with the place—i.e., old; the Vines also are in keeping with the structures, being old also, perhaps octogenarians; and the heating apparatus was arranged during the very earliest days of hot-water engineering. Grape-growing is not a speciality, for not only are the Vines much too old for active work, but the houses are necessarily crowded with plants, especially during the winter and spring, which have as much attention as can be given them, yet useful Black Hamburg and Muscat Grapes are grown. Sir Henry evidently treats the Vines as he would good old servants—respects them for their long services, and his gardener, Mr. Paton, just "makes the best of them." That he would make better of young Vines is evident, for three young Alicantes had been planted, and although they proved to be the Kempsey Alicante (Black Morocco), which is by no means an easy Grape to finish well, they were bearing a good crop, the bunches full, and the berries regular. The Peach house is in the same range. The front wall is of brick, and the trellis is nearly flat, being not much more than 3 feet from the ground at the back, thus admitting light to the back wall, which is also covered with trees which are healthy and vigorous. Besides the vineries there is a more modern span-roofed structure in two divisions for the cultivation of stove and greenhouse plants; and here we find "plants of the past," such as *Witsenia corymbosa*, *Eucomis punctata*, *Linum trigynum*, *Swainsonia alba*, *Campanula garganica*, and others that are not seen everywhere; but in contrast with these old favourites are modern tuberous Begonias and Chilwell zonal Geraniums. On the roof of the greenhouse *Plumbago capensis* and *Tacsonia Van-Volxemi* are vigorous and floriferous. *Mandevilla suaveolens* and *Lapageria rosea* are also amongst the roof plants. On the roof in the stove are *Stephanotis floribunda*, *Passiflora princeps*, and the strikingly effective *Ipomæa Learii*; the beautiful blue flowers of this *Ipomæa* are very attractive but not long-lasting. The general occupants of the stove consist of popular decorative plants, such as *Crotona*, *Caladiums*, *Eucharises*, *Anthuriums*, *Pandanuses*, *Alocasias*, and similar plants that can be employed for vase-decoration in the mansion, also a few Orchids. The singular *Strelitzia reginæ* was also flowering. In the small borders outside the houses are several old and good herbaceous plants, also a mass of the Cape bulbous plant *Anomatheca cruenta*, which appears to have become naturalised. Certainly it is quite hardy here, for it has remained unprotected for many years, and has increased and multiplied.

Behind the glass range is the frameyard and garden offices. This department is only noticed because it affords an instance of the successful establishment of the brilliant hardy *Tropæolum speciosum*, which is generally as unsatisfactory in the south as it is magnificent in the north (Scotland). Mr. G. F. Wilson has during the past season exhibited flowering sprays of this plant, proving that it will thrive in the south, and "D. Deal," has suggested that a cool shaded position is the most likely to be suitable for it. The plants at Holme Lacy suggest that he is right. They were planted in a moist corner, and were trained up a wall which only receives the sun for a short time during the afternoon, and they were thriving as well as if they had been transplanted in Scotland. One of the most attractive displays that I have seen produced by this *Tropæolum* was on the cottage of the renowned Grape-grower, Mr. Dickson, at Arkleton, and I mention it to note that the rainfall in that district of Dumfriesshire sometimes exceeds 60 inches per year. It is clear, therefore, that the Flame *Tropæolum*, as it is popularly called, is a moisture-loving plant, and in the dry districts of England a cool and shaded position is the right place for it.

There yet remains the "cordon" wall to be noticed. This, so far as fruit-growing is concerned, is the best feature of Holme Lacy. The trees are on the south side of the wall which bounds the kitchen garden on the north. They are about 15 inches apart, and are trained at an angle of 45° with their points to the west. Every portion of the wall is covered from base to summit, and the trees are in the most fruitful condition. These cordons have produced the finest fruit that has been grown in that part of the country, and has on several occasions occupied the premier position at local exhibitions. Even during the past year when fruit was so scarce several of

these trees were laden with fruit—laden, perhaps, fully too heavily considering that a few fruits, and these as fine as possible, are what the owner covets. The trees are, however, admirably managed, and reflect much credit on the gardener, also on his predecessor who planted and trained them (Mr. Wells), now of Mr. Munro's nursery at Potter's Bar, who was for a long time gardener at Holme Lacy, and where he has left a name that is cherished by those who had many proofs of his ability and urbanity. The collection of Pears numbers upwards of eighty of the best varieties. There are several fan and horizontal-trained trees, but that portion of the wall covered with the cordons is not only by far the most ornamental, but is also the most profitable. It is a wall, indeed, of which both the owner and gardener may be justly proud. This system of growing Pears is so simple, attractive, and profitable that it is a little surprising that it is not more generally adopted in English gardens. A visit to such collections as those at Holme Lacy and in Mr. Roger Leigh's fine fruit garden at Barham Court, Maidstone, under Mr. Haycock's skilful charge, afford convincing evidence of the value of the method, which is certainly worthy of being more extensively adopted than it is. The cordon wall at Holme Lacy is one of the most complete in England, and is emphatically worthy of high commendation and imitation. The gardens at Holme Lacy are under the charge of Mr. Paton, and the good keeping of the grounds bears testimony to the attention that he bestows on them in rendering them enjoyable not only by his employer but also by the inhabitants of the district, for the gardens are by the kindness of the owner free on one day in each week during the summer months, and are visited by admiring thousands from the adjacent towns.

Very briefly the cider orchard must be referred to. It is extensive, and the trees are very old. They are on grass, and have received no pruning apparently for years past. Although last year was notoriously a bad fruit year, the trees in this orchard were almost broken down by their weight of fruit. It is no exaggeration to say that the fruit on the ground under the trees might have been shovelled up by cartloads. Gathered it never is; it is dashed the same as walnuts and carted to the stores and mills. Here in the orchard is the Redstreak, the Scudamorean Crab, "whose pulpos fruit with gold irradiate and vermilion shines." Here also is the Foxwhelp, which Knight valued so highly and at the same time predicted its gradual decay, for, as he said, "the grafts partaking of the life of two centuries can give nutriment only, not new life." The Red Must, an esteemed old native, is here; also the Pawson, or, in the local vernacular, "Parson," which looks better than it is. Here also is the Hagloe Crab, the Foxley Apple, the Friar, and many others which belong to a race quite distinct from the culinary Apples in general cultivation.

But I must leave the Apples to notice what I shall make bold to write as the most wonderful Pear tree in the world, and will leave it to others to disprove the correctness of this estimate by submitting authenticated instances of other trees that are more remarkable. This extraordinary tree is growing in the vicarage garden of Holme Lacy, which, with the old Norman church, is situated at more than a mile distance from the Hall and village. I have alluded to this as a "travelling tree," and the term is, I think, appropriate, for the tree has travelled under and over nearly an acre of ground. Much of it has been cut down from time to time owing to its having encroached on the house, and now only a relic of its former magnitude remains, but that relic is full of interest. It has been described as resembling the Indian Banyan tree, and the comparison is admissible. This Pear tree appears to have in a strange abnormal fashion crept along the ground, sometimes quite beneath the surface and sometimes partly above it, for it is not the roots that have thrown up suckers, one here and another 50 yards distant, but the stems; these can be plainly traced. Whenever a branch has fallen to the ground it appears to have derived renewed vigour and has crept along for several yards, when an upright growth has issued; this in turn has perpetuated the singular freak, until the tree has travelled over the space of ground mentioned. At the present some portions of this extraordinary tree are growing in the field outside of the garden, and other portions are quite on the opposite side of the large lawn of the vicarage. That these parts belong to the same tree and have issued from the same root appears almost incredible, but that it is so the testimony of the family is corroborated by the huge stems that in places can be distinctly seen trailing, serpent-like, along the ground. Some of these terrestrial branches have, however, been removed

and others are buried beneath the surface, yet that the tree has spread in the manner described there is ample evidence. It is one of the small perry Pears, and when the tree was in prosperity, and before portions of it were cut down, it is recorded that from fourteen to sixteen hogsheads of a hundred gallons each of perry have been made from it in one year. Is it not, therefore, a wonderful specimen? and is not the term "travelling tree" justifiable?

The church contains several splendid monuments, some of them of great antiquity, others more modern. The park contains similarly splendid trees, ancient and modern, many of which were unfortunately "laid low" by the terrific gales of last September. Even amidst the wreck of timber caused by that tornado Holme Lacy was beautiful—beautiful in its desolation. What, then, must it be in the fresh garb of its summer dress?—J. WRIGHT.

STEAM TREE-FELLING MACHINES.—A public trial of these, patented by Messrs. A. Ransome & Co. of Stanley Works, King's Road, Chelsea, took place recently at Roupell Park. The apparatus, which can be carried by four men, is laid on the ground near to the tree, to which it is fixed by two jaws and by a chain placed round the tree just below the saw-cut and drawn taut by a screw. The first tree felled was an Elm, 2 feet 9 inches across the cut. The machine having been adjusted the saw was set in motion, and the tree fell in less than four minutes. The second tree was also an Elm, 3 feet across the cut, and the tree fell in a little less than eight minutes. The third Elm, 2 feet 6 inches in diameter, came down in seven minutes and a half. When the work goes on uninterruptedly the task is accomplished with great rapidity. Four or five other trees were felled, one of them, with a diameter of 22½ inches, being sawn through in a minute and a half. In the heart of one of these trees was found an entire brick. The saw was not made to cut bricks, but as it was driven by steam it had no time to debate the point, and so went right through the impediment, with the loss of a tooth. As the saw cuts well into the tree wedges are driven in, as is usual in felling. The pressure of steam required for the felling of such trees as were operated upon is about 50 lbs. from a three or four-horse-power boiler.

WALL PROTECTION.

THE plan which I enclose is a system which I think will be found very useful for the protection of wall fruit. It consists

Fig. 9.—Wall Protection (Interior).

of a simple though diverse application of the grooved rafter. By making the groove oblique and of the length of the glass putty is entirely dispensed with, and the glass may be removed

at pleasure. I have now tried a model of the plan for some months, and it has safely passed through the ordeal of the violent gales which have been rife this autumn.

The oblique grooved rafter not only dispenses with glazing, but it also provides for the free and perfect ventilation of the structure. The air is admitted through the spaces left open at the end of each pane; in fact the ventilation is too great, but it can be regulated either by closing the openings with thin strips of glass or perforated zinc.

The distance from the wall is a matter of opinion; 4 feet is ample for easy circulation, and is enough for attention to the trees. The oblique grooving admits of the entire removal of the glass during the summer months, and I think most amateurs and professional gardeners will find this a great convenience. The comparative cheapness with which such a structure may be placed on the walls will render it accessible to many who do not care to give the attention required for a house. I believe that all kinds of fruits may be grown, and that Grapes will thrive as easily as Peaches. I shall be happy to show the model to any of your readers who wish to examine it.—T. FRANCIS RIVERS, *Sambridge north*.

NOTES AND GLEANINGS.

THE Council of the Royal Horticultural Society have appointed Mr. SAMUEL JENNINGS, F.L.S., F.R.G.S., as Assistant Secretary. Mr. Jennings has had considerable experience in administrative affairs in India. He was a Vice-President of the Agri-Horticultural Society; he managed for some time the Botanic Garden at Allahabad, and is favourably known by his beautiful work on Indian Orchids, published by Messrs. Lovell Reeve & Co.

THE ordinary monthly meeting of the SCOTTISH HORTICULTURAL ASSOCIATION was held in 5, St. Andrew Square, Edinburgh, on the evening of the 7th inst., Mr. Hugh Fraser, Vice-President, in the chair. There was a large attendance of members. Seventeen new members were admitted, and thirteen names were proposed and seconded for admission at the next meeting. Mr. James Grieve, of Pilrig Park Nursery, read a paper on the Phlox and Pentstemon. At the outset he touched upon the neglect of these good old plants by some gardeners, detailed the history of their introduction, and traced the progress of their cultivation to the present time. He gave his own experience as to the different modes of culture, and mentioned the various points requisite to make a good flower. As decorative plants their various uses were also named. At the conclusion of the paper several members expressed their opinions regarding the usefulness of these plants, referring to their suitability to the wants and demands of particular gardens. The thanks of the meeting were awarded to Mr. Grieve for his highly practical and useful paper. It was then intimated that the subject for discussion at the next meeting was "The Construction of Vine Borders," to be opened by Mr. Wm. Priest, Newbattle Gardens, Dalkeith.

MR. MOORMAN, writing in reply to "A KITCHEN GARDENER" on LATE-FLOWERING CHRYSANTHEMUMS, considers there are few, if any varieties, that can be relied on to bloom in January during ordinary seasons. The past season was three weeks later than usual, consequently Chrysanthemums are correspondingly later in going out of flower; but he does not know of any varieties that can be depended upon for flowering throughout January.

THE death is announced of the Rev. JOHN FOUNTAINE of Southacre Rectory, Norfolk. Mr. Fountaine was an earnest advocate of the orchard-house culture of fruit trees, and invented what is known as the railway system of fruit-growing—the trees being grown in pots on a truck placed on metals for the purpose of being drawn out of the house into the open

air as required. The system was tried at Chiswick but did not prove a success, and the plan, which Mr. Fountaine advocated in a pamphlet, never became popular. Mr. Fountaine, who was much esteemed by a large circle of friends, died on December 28th, in his sixty-third year.

— ONE of the most distinct of Evergreen Oaks is *QUERCUS AUSTRALICA SEMPERVIRENS*. Unlike the ordinary Evergreen Oak, *Quercus Ilex*, it has large foliage resembling the British Oak, *Q. pedunculata*. We recently observed trees of the Turkey Evergreen Oak referred to in Mr. Richard Smith's Nursery at Worcester, and could not fail being struck by the large bright green leaves when those of other Oaks were perishing on the branches or decaying on the ground. *Quercus australica sempervirens* may be described as an evergreen English Oak; it is very hardy and ornamental.

— AS difficulty is frequently experienced in removing RUST FROM STEEL, such as garden tools and household appliances, we submit the following mode as one of the best and simplest for brightening rusted surfaces. Cover the metal with sweet oil, to be well rubbed in, and in forty-eight hours afterwards rub with finely pulverised unsalted lime.

— SO popular have PALMS become as domestic plants, and so admirably do they thrive in the dry air of living rooms and in ill-lighted corridors, that they are offered in large numbers in Covent Garden, and from thence they may be seen on the barrows of costermongers and on the heads of plant-hawkers in the streets of London, who endeavour to earn a honest penny in distributing them over the homes of the metropolis. During the first week in January the weather was so mild that Palms and the hardier *Dracaenas* could be conveyed in the open air without being sheltered and without receiving any injury. The Palms which are the most extensively grown for market are *Latania borbonica* and *Seaforthia elegans*, both of which are as ornamental when small as they are stately when of larger growth. Plants of these Palms in 5 and 6-inch pots are valuable for decorative purposes both in rooms and conservatories, in town and in country.

— INDIAN FRUIT AND NUT CULTURE.—A notable feature of a recent meeting of the Toronto Fruit Growers' Association was the presence of one of the chiefs of the Tuscarora Indians. He has entered largely into the culture of nut-bearing trees, and gave an interesting account of his success to the meeting.

Fig. 11.—RIVERS'S WALL PROTECTION (EXTERIOR). See Page 52.

— MANY have observed that VARIEGATED-LEAVED PLANTS in certain soils and situations incline to lose their variegation more than in others. By recent experiments it has been shown that the ash of white and green leaves differs very much in its chemical composition. According to these experiments it has been shown that the ash of white leaves of *Acer negundo* contained 45.05 of potash, while the green contained but 12.61. The white leaves contained 10.89 of lime, the green 39.93. Quantitative analyses upon *Hedera Helix* and *Ilex aquifolium* show about the same proportion of difference between the variegated and green leaves. We may infer, therefore, that if we wish to preserve or increase the variegation in plants they must be fed with a maximum of potash and a minimum of lime.—(*Rural New Yorker*.)

— TEA ROSE CORNELIA COOK is now, says the "New York Rural," one of the most popular of all the Roses used by the bouquet-makers of New York during the winter months. The buds are long and much pointed, the colour being nearly pure white and the fragrance delicious.

— WE join in the regret which is so general among florists at the death of Mr. SAMUEL COOPER of The Hollies, Timperley, Cheshire. Mr. Cooper was an ardent cultivator of florists' flowers, and possessed excellent collections of Auriculas, Pinks, Tulips, &c., which he exhibited successfully for many years. He was most genial in his disposition, and met with a warm welcome in all gatherings of florists. Mr. Cooper was the winner of prizes in the Alpine classes at the Crystal Palace National Auricula Show which was held last year on April 24th.

— A VIENNA journal, in relation to PREPARING SPECIMENS FOR THE HERBARIUM, says, "Most botanical students must have regretted the change of colour which plants undergo in drying. We are informed that this inconvenience may be obviated by dipping the plants in a warm mixture of one part hydrochloric acid and six hundred parts alcohol, shaking them to get rid of superfluous fluid, and then laying them in warm blotting-paper, which ought to be changed at least once daily. By this means the plants will not only dry quickly, but will also retain their natural colour."

— A LARGE stock of JAPANESE PLANTS have arrived in Paris for the approaching Exhibition, having been brought over in charge of two native gardeners. They were welcomed by those in charge of the horticultural department of the city of Paris, who at once placed their grounds, hothouses, and even their staff at the service of their foreign *confrères*. The latter part of the offer was, however, not accepted, in consequence of the Japanese not being able to speak any language but their own. Besides this, they evidently considered themselves quite capable of managing the plants under their charge without extra help. The plants consist of deciduous and evergreen shrubs of various kinds and a few Conifers, all of which are dwarfs, the tallest being barely 3 feet high. The collection includes a few fruit trees, several Magnolias, *Daphne japonica*, *Gardenias*, *Spiraeas*, *Osmanthus*, &c., also a number of Japanese Maples, among which will no doubt be found several of the well-known species with which we have long ornamented our gardens. Unfortunately a large proportion of these plants

have suffered much from the effects of their two-months voyage, a number having died. A large quantity of Orange trees perished, which is particularly unfortunate, because some of them may have belonged to the so-called hardy sorts of which we have heard so much. On the other hand, it must be remembered, that without in any way wishing to call in question the gardening ability of our foreign colleagues, we must warn them that they are not yet at the end of their disappointments, and it is much to be feared that their want of experience of the climate of Paris will bring about much trouble and many vexations. We may add that these gardeners are strong, robust, and intelligent, and handle their tools, which are few in number, with great dexterity.—(*Revue Horticole*.)

—THE "ROSE AMATEUR'S GUIDE" by Thomas Rivers has reached its eleventh edition, a fact which speaks in the most practical terms of its excellence and acceptability. As praise would be superfluous we simply extract from the preface of the last edition. "The Rose shows of this year have been singularly successful in spite of an adverse season; the beauty of the blooms exhibited has elicited the remark from a French Rose-grower that no Continental Roses are equal in brilliancy to those of England. This is very flattering to English Rose-growers, more especially as the acknowledgment comes from one of a nation hitherto supposed to possess a monopoly both of Rose-growing and Rose-raising; the English seedlings are now fully as good as any raised in France, and we may hope that the improvement will continue." We join in the hope, and have no doubt of its being realised.

DEATH OF MR. ANDREW MURRAY.

WE regret having to record the death of Mr. Andrew Murray, F.L.S. He died on the 10th of the present month after a lingering illness. Mr. Murray was originally bred to the profession of the law, and belonged to the Corporation of Writers to Her Majesty's Signet in Edinburgh. He early interested himself in natural history subjects, and was one of the originators of the Orogen Committee in Edinburgh, which was a Society formed for exploring the western parts of North America chiefly for new Conifers, and the result of their labours was among other fine trees that have become popular, *Cupressus Lawsoniana*, *Pinus Jeffreyi*, *Abies Pattoniana*, &c. In 1858-59 he was elected President of the Royal Physical Society, and he filled also the office of President of the Botanical Society of Edinburgh. In 1861 Mr. Murray was chosen by the Council of the Royal Horticultural Society to succeed Mr. Booth as Assistant Secretary, which office he held for a few years, and on his retirement he was elected on the Council. For some years Mr. Murray has been engaged under the direction of the Science and Art Department of the Privy Council in preparing a museum of economic entomology, which is now to be seen in the Bethnal Green Museum, and which exhibits in a marked degree not only Mr. Murray's perfect knowledge of this subject, but his attainments as an accomplished artist. As an artist he was quick and facile, and could sketch off in the best style a landscape or an object without any difficulty. Soon after his appointment to the Horticultural Society he published in 1863 an illustrated volume entitled "The Book of the Royal Horticultural Society," dedicated by Her Majesty's permission to the memory of the late Prince Consort. In 1866 he published his "Geographical Distribution of Mammals," in which he brought together such facts as were known, and illustrated the distribution by coloured maps. He died at Bedford Gardens, Campden Hill, Kensington, in his sixty-sixth year. Mr. Murray was the son of Mr. William Murray of Conland, and was born in Edinburgh in 1812.

WORK FOR THE WEEK.

KITCHEN GARDEN.

IN order to meet the demand for certain kinds of vegetables it is desirable to provide liberally of such crops as Peas, a good breadth of which should now be sown as soon as practicable, William I. being recommendable for its hardness and earliness. We prefer a south border for early sowings, the rows pointing north and south, sowing in a double row—that is, drawing a drill on each side of the line, the rows 8 feet apart. To guard against vermin the seeds of all kinds subject to the attacks of mice as well as birds are thoroughly moistened with paraffin water, about a quarter of a gill of paraffin to a gallon of water, stirred well up with the seeds in it. The water is then poured off, and the seed is thoroughly coated with red lead. We find no injury result to the seed, whilst no quadruped or biped interferes with it. Our

early sowings are just covered with soil, and have an inch of sifted ashes placed over the rows to afford protection from frost and slugs. Broad Beans are treated in a similar manner, of which a sowing of Early Longpod should be made the earliest opportunity. Cauliflowers and Lettuces in frames or handlights to be kept hardy by withdrawal of the lights entirely when the external air is over 35°, except in wet weather, when the lights ought to be tilted.

Forcing Department.—Continue to introduce fresh supplies of Asparagus and Seakale roots, Rhubarb and Chicory, at regular intervals, so as to maintain a supply which will need to be regulated according to the demand. Keep up the supply of Dwarf Kidney Beans, which may be sown in pots moderately drained and three parts filled with rich medium-textured loam, placing six to eight beans around the sides of the pot, and pressing them into the soil with the finger up to its first joint. Osborn's Forcing is dwarf and very prolific. We employ 9 or 10-inch pots. It is essential that a light airy position be afforded in a house with a temperature of 85° at night, 65° by day, advancing to 75° and more from sun heat. Sow Radishes and Carrots in alternate rows 3 or 4 inches apart on prepared beds when the soil has become warmed; also plant Potatoes in pits or frames, earthing-up those growing freely. The earliest crops of Potatoes are had from pots three sets inserted 4 inches deep in 12-inch pots, forwarding them in light airy positions in Peach houses or vineries.

MUSHROOM HOUSE.

The earliest beds will now be nearly exhausted. In case of the material not being much decomposed a good soaking of water at from 90° to 100°, with half a pint of salt to every six gallons, well stirred, will often cause a return to bearing; but if the material of the beds be much decomposed it is better to replace them by beds of fresh material. This is a good time to make beds in cellars or any kind of outhouse which can be kept close. Fresh horse droppings with a fourth of short litter form good beds, it being essential that the material be so moist as to form a firm mass by beating with mallets, placing the material in thin layers and beating each very firmly; 12 inches in depth of bed will suffice, but 15 to 18 inches afford more durable beds. When the temperature of the bed falls to 75° insert the spawn in pieces about 2 inches square and 9 inches apart, covering 2 inches by closing the material well around and over the spawn. Within a week the spawn will have spread somewhat if good, and the bed should then be earthed. Turfy loam chopped-up moderately small spread on 2 inches thick and made very firm, with an even and smoothed surface, the soil being so moist when used as to bind. In about six weeks, depending upon circumstances and temperature, ours being kept at from 60° to 65°, the Mushrooms will show themselves. The bed is then to be kept regularly moist, avoiding over-watering, which induces speedy decay of the material, destroys the mycelium, and ruins the crop. Beds in bearing should be daily examined, and any dry places sprinkled with water of the same temperature as the house, letting as little as possible fall upon the Mushrooms. In positions where sufficient heat is not insured a thick covering of dry material is necessary for warmth; but it is a mistaken idea to consider darkness essential to the production of Mushrooms, light with moderate ventilation greatly improving the flavour.

FRUIT HOUSES.

We are convinced that most of the failures of fruit crops under glass arise from an insufficiency of water at the roots; but in badly drained borders over-watering is highly prejudicial. Imperfect drainage should therefore at once be rectified. Vines and Peaches ought never to have the soil dry, even when leafless, for when the soil is allowed to become very dry it is not only a cause of exhaustion (which Peaches and Nectarines resent by casting their buds), but causes much trouble in thoroughly moistening again. Vines in dry borders frequently break irregularly, and their early growth is enfeebled. Our remarks apply to inside borders, which are often kept much too dry.

Vines.—The rods should now be pruned as soon as possible. Any Grapes may be cut with a piece of wood attached, the stems being placed in bottles of water in any dry room with a temperature of about 45°. In pruning cut to a plump eye, the one nearest the main stem; for though the buds near the base of the shoot afford smaller bunches, they are usually more compact and admit of a better finish than the larger looser bunches resulting from eyes at a distance from the rod. Two, or at most three eyes, will be ample provision for a good show of fruit. Strip off the loose bark, avoiding injury by scraping, and dress with the following composition for destroying insects:—1 lb. of soft soap to a gallon of water, brought to the consistency of thin paint by the addition of tobacco powder. If there have been any mealy bug add a quarter pint of spirits of turpentine. The glass and woodwork should be cleaned thoroughly, taking off also the surface soil of the border 2 or 3 inches thick, replacing with good fibrous loam, of which Vines never tire.

Pines.—Plants swelling off their fruit should be syringed overhead occasionally early in the afternoon when the axils of the leaves become dry, and every available surface of the house should be syringed twice a-day. Fruiting plants and starters should have a mean temperature from fire heat of 70°, about 6° lower in

severe weather at night. Allow the temperature to rise to 80° or 85° with sun, giving air at that, and closing at the same temperature. Bottom heat of 80° to 90° is easily obtained by hot-water pipes placed under the bed; but if from fermenting materials see to having them ready for starting a batch of Queens early next month. Successions keep at 60° to 65° at night, 70° to 75° by day.

Melons and Cucumbers.—Sow at once for the first crop, placing the pots in a bottom heat of 75° to 80°, and top heat of 70°. Moderate light loam is best for seed-sowing, though strong loam is preferable for the fruiting beds. The soil being moist no watering will be needed until the seedlings appear. Those requiring Cucumbers early in spring should sow forthwith (they requiring similar conditions to Melons), potting-off the plants singly when the rough leaf shows in the centre of the seed leaves, and watering very carefully, or damping will ensue.

PLANT HOUSES.

Greenhouse.—Use no more fire heat than is absolutely necessary; 45° is a sufficiently high night temperature, falling to 40° in the morning, especially for hardwooded plants. In very severe weather avoid side ventilation, as the cold air rushing through the plants is more or less injurious; but in mild weather admit air very freely. Azaleas endure a lower temperature than most other hardwooded plants, but should be kept from frost, yet the cooler they are the better, especially those required for late bloom. They must not be allowed to get dry at the roots, as they are moisture-loving plants. New Holland or Cape plants advancing for flowering to be more freely supplied with water. Heath keep cool and well ventilated, as they are easily excited into growth by closeness and warmth. Pelargoniums require very careful watering, as when water is abundantly furnished the plants assume a coarse habit of growth. Autumn-struck cuttings having filled the small pots with roots shift into 4 or 6-inch pots, using good loam, with a fourth of well-decayed manure. Pinch out the points of the shoots if not already done, to induce them to break, training those with several shoots, so as to form the ground of the specimen. Kalosanthos are useful decorative plants; keep them near the glass, and water carefully to prevent the loss of the lower leaves. Zonal and Nosegay Pelargoniums intended for summer flowering should be potted and kept in a temperature of 50° to 45°, potting firmly, and not giving too much pot room, as this and loose soil only tend to rank growth.

Orchids being yet mostly inactive, the temperature of the East India house should be 65° day, and 60° to 58° night; Mexican house, 58° to 60° day, 50° night. Not much air will be required, but the atmosphere will need moisture, which may be obtained by damping the floor and stages. Dendrobiums showing flower to have moderate waterings, and if given a slight increase of heat, to encourage the expanding of the flowers, all the better. Odontoglossums require moisture at the roots at all times, especially when advancing for flowering; also *Oncidium* coming into flower to be well supplied with water at the roots, as dryness causes the pseudo-bulbs to shrivel. Plants not in flower of *Calanthe vestita* to be kept dry until they start into growth, some of which will do so soon, when they should be potted. *Phalænopsis* on blocks require frequent syringing, those in baskets or pots to have the surface kept moist. Top-dressing and potting must soon have attention, therefore have ready the requisite materials.

TRADE CATALOGUES RECEIVED.

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Vegetable, Flower, and Farm Seeds.*

Dick Radcliffe & Co., 129, High Holborn, London.—*Catalogue of Vegetable and Flower Seeds and Garden Requisites.*

William Rumsey, Joyning's Nurseries, Waltham Cross.—*Catalogue of Select Vegetable, Flower, and Farm Seeds.*

Dickson & Sons, 1, Waterloo Place, Edinburgh.—*Catalogue of Garden Seeds and Implements, also List of Gladioli.*

Thomas Bunyard & Sons, Maidstone.—*Descriptive Catalogue of Vegetable, Flower, and Agricultural Seeds.*

TO CORRESPONDENTS.

. All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

ZINC LABELS (J. H. A.).—The electric action you refer to is so weak that it has no effect upon the branch to which the label is attached. It only injures the labels, often causing them to drop off the trees.

TOKAY VINE FAILING—INARCHING (A Subscriber).—White Tokay has always done well with us, but we have seen it fail with others, as it has done with you. Probably it has made more wood than could be thoroughly

ripened. We advise you to inarch one Gros Colman and one Trebbiano on it. The latter is equally as fine a Grape as the Tokay, and Gros Colman will be a fine addition to your other sorts. As you have not pruned the Vine cut the main stem down to the two lowermost shoots, which should branch out on each side like a Y. Allow these two shoots to start into growth, and as soon as the leaves begin forming inarch the Gros Colman on one of the shoots and the Trebbiano on the other. Inarching is simply accomplished by taking a slice about the length of your finger from the side of the stock and the same from the Vine that has to be put on it; make the cuts as near the same size as possible, and put them face to face, then bind the two firmly together with a piece of strong matting. Three weeks after tying take this off and tie it up again, but not so firm. In six weeks the union will be complete. Some cut away the Vine at this time, but it is best to leave it until autumn.

DRIP FROM COPING (J. A.).—The drip is not so heavy as to be injurious to the roots of the fruit trees.

NIGHT SOIL (C. H. M. W.).—It has no influence in the production of wireworms.

JASMINE BUDS FALLING (B.).—Roots deficient in action, probably owing to want of moisture. Apply copiously tepid water.

CONDOR PEACH (O. S.).—This is a comparatively new Peach. It was raised by Mr. Rivers from Early Silver, a large Peach, which was raised from the White Nectarine. Condor is a large Peach, bright crimson in colour, and has a rich piquant flavour. The tree is hardy and a good grower. It ripens at the end of August or beginning of September.

CLASSES AT HORTICULTURAL SHOWS (Cockgate Street).—By "gardeners" only those who receive wages from an employer, not a nurseryman, should be intended. Amateurs should be gentlemen who either are their own gardeners or who have them in their service. Cottagers ought to be labourers. The committee of each horticultural show would do well if they defined in their schedule the class of persons entitled to compete for each prize.

EARLY VINES FAILING (F. Z.).—Without knowing the weight of crop your Vines produced last year we cannot tell whether they were overcropped or not, but the fruit hanging on them until September would not injure them in the least. We suspect your Vines have not failed, but are only shy in starting into growth, chiefly owing to their being started a month earlier this year than they were last. The beginning of November is very early to start Vines, and as a rule they will make as much progress in one month in spring as they do in two in autumn. As the heat from the manure has 2 feet of soil between it and the roots they will get no assistance from it. For the next three weeks keep the temperature of the house at 60° by night and 65° or 70° during the day. Damp the rods once a-day through the syringe and keep the atmosphere always humid. Their wood will not be sufficiently matured to start them into growth again by November of this year, but they might be started in January, 1879, and after that they will bear starting into growth a fortnight earlier every season until you have reached the beginning of November. Few Vines freely submit to be started a month earlier one year than another.

FRUIT TREES FOR A SMALL GARDEN (A. Oldfield).—The pyramidal form is quite the best for a small garden. For fruit trees in pots the size of the pot will, of course, vary in proportion to that of the tree, those ranging from 12 to 18 inches in diameter being in common use.

FRUIT AND VEGETABLE CULTURE (Idem).—You can have no better guide in these matters than the cultural notes given in this Journal under the heading of "Work for the Week." The "Garden Manual," published at this office, will also afford you much information. It is sent post free for 1s. 8d.

LIQUID MANURE FOR AZALEAS (F. B. M.).—It will assist the development of the flowers if you give them clear guano water, using a quarter of an ounce to each gallon of water. Watch closely the process of expansion, using or withholding the manure as may appear necessary. As a general rule a liberal dose once a-week will suffice.

ANTS IN A GREENHOUSE (Idem).—A couple of toads will clear off a colony of ants with marvellous celerity, as well as many other insect pests. We keep two or three toads in every one of our glass houses. When we see ants on a plant we always have a suspicion that it is infested by insects. Keep your plants quite free from all insect pests and you will find the ants less troublesome.

MISTLETOE PROPAGATION (A Thirteen-years Subscriber).—From the end of January until the end of March inclusive is the best season for sowing the berries. This may be done by making two cuts on the under side of the branch of an Apple, Crab, Thorn, or Lime tree in the shape of a V, the cuts being made through the bark quite to the wood; raising the tongue of bark made by the cuts, taking care not to break it, squeeze from the berries one or two seeds neatly under the bark, and let the tongue back into its place; the operation is then complete. We have had them grow freely by squeezing the seeds from the berries on a smooth part of the bark on the under side of the branches, the seeds adhering to the branches by the glutinous matter. You may also graft early in May, making an incision in the bark of the tree and inserting into it a thin slice of Mistletoe with a bud and leaf or leaves at the end; or you may put in large pieces of Mistletoe, taking a piece of wood from the tree so as to correspond with the graft, the latter being prepared as in notch-grafting—with this difference, that for the Mistletoe an incision is made below the notch, as in crown-grafting, to receive the scion, a shoulder being left on the scion to rest on the notch made in the stock. Budding may be performed from the beginning to the middle of May, the buds being put in with the wood, a short heel of wood being retained below the bud for insertion.

MYRTLES NOT FLOWERING (W. H. W.).—You have done well to repot your old Myrtles; it will reinvigorate them and induce free growth, which will subsequently afford plenty of flowers.

POTTING FERNS (Idem).—Ferns do not require repotting annually. Let their condition be your guide, undersized fronds and a tendency to deteriorate being a sure sign of their requiring fresh soil.

ERRATUM.—The spread of the branches of the Trysting Oak at Holme Lacy, noticed on page 495, is 1365 square yards, not feet, and when measured a few years ago the tree was estimated to contain 1842 cubic feet of timber, taking all that would square to 6 inches.

ELEVATION OF VINERY—VINES FOR EARLY AND LATE HOUSES (A. B.).—A vinery of the dimensions you name should be 16 feet high at the back and 3 feet 6 inches at the front. The Vines should be planted 4 feet apart. At this distance six Vines will be required for each division. In the early

compartments plant three Black Hamburgs, one Foster's Seedling, one Buckland Sweetwater, and one Royal Muscadine; for the late division two Gros Colman, one Black Alicante, one Lady Downe's, one Trebbiano, and one Syrian will meet your requirements.

PEACH TREE BUDS DROPPING (Amateur).—We have frequently painted the pipes in Peach and other fruit houses with lampblack, and never found any injury to the trees resulting from it. Glahurst compound applied at the rate you mention would not injure anything. We suspect the cause of the buds falling is wholly owing to the trees having been started into growth in too high a temperature. For the first twelve days after the house is closed the night temperature should not exceed 50°, and 60° by day. When in flower these should be increased by 5° night and day. The best thing you can do now is to keep the house quiet at these figures, and spread leaves and dung over the roots to the depth of 18 inches. It requires more skill than most amateurs possess to start Peach trees successfully into growth in December.

SUMMER-FLOWERING CLIMBING PLANTS (A Reader of the Journal).—*Manrandya Barclayana* is one of our best climbers, making a rapid growth, flowering freely, and of much elegance and beauty in both foliage and blossom. We have now four varieties—white, purple, crimson, and pink. It is perennial. *Nasturtiums* and *Convolvulus* of many colours, the curious yellow-flowered *Calophoras*, the old favourite *Tropaeolum canariense* with its bright yellow flowers, the purple and white *Cobaeas* are suitable, and you might add with advantage that fine old perennial climber *Eccremocarpus scaber*, which grows so freely from seed and makes such a brilliant show with its rich orange-scarlet flowers.

ROSES FOR SOUTH AND EAST WALLS (A Constant Reader).—You are apparently unaware that it is unusual to plant "Perpetual" Roses against walls owing to the slowness with which they cover wall space in comparison with *Tees* and *Noisettes*. In compliance with your wish, however, we name six varieties—*La France*, *Beauty of Waltham*, *Marquise de Castellane*, *Annie Wood*, *Comtesse d'Oxford*, and *Boule de Neige*; but for ourselves we should prefer such sturdy ramblers as *Gloire de Dijon*, *Climbing Devonensis*, *Homère*, *Cheshunt Hybrid*, *Goubault*, and *Souvenir d'un Ami*. Have you given *Maréchal Niel* a fair trial? Try half a dozen of it in various positions and aspects, and you will probably find one or two of them to answer as well as your other Roses, while the others may fail. Such has been our experience in the culture of this fine Rose. Let the whole of your Roses be on stout healthy Briars.

CONVERTING YOUNG STANDARD FRUIT TREES INTO PYRAMIDS (A Constant Reader).—Cut the heads clean off to within 2 feet from the bottom, and you will have plenty of shoots springing forth from the part you retain. Let the whole of them grow, thin out next autumn, taking the top shoot to form the future stem, and shortening it then to about a foot. Continue this treatment with a moderate summer pruning, and you will have some fine pyramids three or four years hence. We presume that the trees have been grafted low—just above the ground line.

LILIUM AURATUM (Rus in Urbe).—Do not lose a day in potting the whole of your bulbs in rich loam or garden soil enriched with manure, plunge the pots in ashes or in a cold frame, and as soon as the roots reach the sides of the pots—which they will not be long in doing, say by the end of February—turn out those you intend growing in beds, and treat your pot plants precisely as has been advised in the notes to which you refer.

FRUIT TREES FOR A CONFINED SHADED POSITION (G. E. C.).—With a wet heavy soil Plums, Pears, and Cherries will probably answer very well. Raise the soil somewhat above the ordinary level for each tree, and mix plenty of gritty matter with it, such as broken stones, bricks, mortar rubbish, or coal ashes, and enrich it with a little manure. We are not clear as to the number of trees you require. Here are three hardy varieties of each. *Pears*.—For September take *Williams' Bon Chrétien*, for October *Fondante d'Automne*, and for November *Doyenné du Comice*. *Plums*.—*Purple Gage* and *Green Gage* for eating, and for cooking you ought certainly to have *Victoria*, which will probably answer better in your peculiar circumstances than any other fruit of any kind. *Cherries*.—For June Early *Purple Gage*, for July *Governor Wood*, and for August and September *Morello*.

FRUIT FOR SOUTH WALL (F. H.).—The Pears may be *Beurré Diel*, *Glou Morceau*, and *Winter Nelis*. The Plums *Green Gage*, *Coe's Golden Drop*, and *Iceworth Imperatrice*.

PLANT ON WET PLACE (R. W.).—It is the *Arctium Lappa*, the Great Burdock.

INSECTS (A. B.).—Boil 4 ozs. of quassia chips for ten minutes in a gallon of soft water; strain off the chips and add four gallons of water, and with this syringe plants or trees infested with aphides.

NAMES OF FRUIT (M. D. Woodford).—We do not recognise your Apple.

NAMES OF PLANTS (W. K.).—1, *Sericographis Ghiesbreghtiana*; 2, *Physalis edulis* (Winter Cherry); 3, *Saxifraga Gmelini* or *hypnoides*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

FARM-HORSE MANAGEMENT—continued.

BRICKS are sometimes used for stable floors; they are, however, generally absorbent and hold urine, giving off foul air. When hard and grooved they will not bear the tread of heavy horses which break up the grooves, whilst the broken surface retains decaying matters, rendering the air impure. All these floors require a gutter and drain to carry off the liquid manure, and are objectionable whether the urine is retained in a tank or allowed to pass away into the farmyard. In the former case injurious gases are generated and often return into the stable; in the latter it is either wholly or partially lost as liquid manure. The only time it is available is where there is pasture land near lying at a lower

level, whereby, in conjunction with the rainfall at the homestead it can be used for irrigation purposes.

Having stated our objections to the farm stables as we generally find them, we will offer a few observations on the system of earth floors we have used and seen in use on various farm premises. The laying of earth floors involves no great expense. The first thing to be done is at all leisure times to collect all the loamy earth that can be obtained on the farm from the roadsides, the ditches, the borders of fields—in fact, wherever it can be conveniently obtained within easy distance; and where other soil is not available we must resort to the sand pit, but we prefer a rather strong loam to a sandy loam, as being better adapted for absorbing and fixing the manure contained in the urine, and at the same time it makes a more compact and harder floor. In storing the earth for use it is either put into a covered hovel or shed, or otherwise made up into a compact heap and thatched with turves, hedge trimmings, &c., and after a time when it has become mellow and quite dry and required for use it is then picked down, broken fine, and passed through an ash screen or half-inch sieve in order to remove stones, sticks, &c.; it is then ready for use. Our plan in converting an ordinary stable for our purpose is to take up the stone or brick floors, under which is usually found a quantity of material which makes first-rate manure, having been saturated with urine for a long period. The value of this will often repay the expense of the change. We then excavate the ground 2 feet in depth, making a pit for the reception of the earth, which should extend from the manger or feeding-trough back to the pathway, which may be left undisturbed—about 4 feet in width, if the building is large enough, otherwise a 3-feet pathway will do. We always take care the pit shall be from 10 to 12 feet in length from manger to feeding-path. We then fill in the dry screened earth a little at a time, ramming it down hard and firm during the process of filling with an iron-head rammer, and filling up to within a few inches of the level of the pathway at the back of the stalls, and made quite level over the whole surface of the floor, so that the whole area of the floor may be available for absorption. When made firm by the rammer the earth will not sink or tread into holes or puddles, but will soon become as hard almost as stone, and yet it most readily absorbs the urine and renders the air of the stables pure and pleasant for the animals to live in. Under this system during a number of years our horses were perfectly healthy, and we estimated that our animals lived and were able to do their work for several years longer than we ever had them before upon the stone floors as before described. At the same time we obtained all the liquid manure (the solid excrement being removed daily), and we found that the period for renewal of the earth would vary from nine to twelve months, according to the nature and dryness of the earth. When filled into the pits it makes a great difference, too, whether the attendants carry out their orders, because if details are not attended to, this, like any other system, will not answer the purpose intended.

In connection with the earthen floors is a great saving of straw, a warm and comfortable bed to lie and stand upon, added to which the horses' feet will always be found in much better condition for shoeing, &c. These observations apply entirely to stall stables. If, however, the horses were allowed a loose box 10 feet by 12 feet, with a 2-feet pit filled with earth in the same way, the earth would not require removal for two or three years, simply because they would not drop their urine upon one particular spot. We hope, however, to return to this subject as applied to stables for nag and carriage horses, &c., at a future time.

The ventilation of stables is a matter of prime importance, and for this reason we disapprove of lofts over the horses with feeding racks for hay; but in preference we like to have the stable open to the roof, which secures ventilation, and we prefer feeding-mangers only instead of racks overhead. Granivorous animals should never be required to take their food from a high rack. The manger should be 3 feet high, 2 feet wide, and 1½ foot deep, and in the case of double stalls 10 feet wide when the horses stand in

pairs, each being tethered to the corner of the stall. A space of 2 feet at either side should be divided off for the animals to eat their corn, roots, and other food separately, leaving the centre space for them to eat their chaff, hay, &c., in common. We think that in feeding farm horses they should never be without some green food both in winter and summer, and we consider the best vegetable food is carrots, although they will do well upon Swedish turnips or mangel; but the roots should always be given with chaff, meal, or crushed grain.

In conclusion, we will refer to the best position or frontage for a farm-horse stable. It is a common practice to place it fronting to the south or south-west, but we prefer the stable to face the north or north-east, as working horses seldom suffer from cold in winter, and as they have to contend with all sorts of weather whilst at work they should not be too closely confined when housed. Again, in the summer time when the entrance to the stable and the windows face the north the animals derive much comfort when the sun is excluded from the stable as much as possible, seeing that flies trouble them very much, and we know flies follow the sunlight. It is also common to find the stable to face the farmyard. This we object to, because working animals are continually going to and fro, which often disturbs other stock, therefore the approach to the stables should be as easy of access as possible without gates or other impediments.

WORK ON THE HOME FARM.

This being the duller part of the year for farm work, if all the wheat has not been sown the sooner it is put in the better; every day is an object. Now the land is close and heavy the wheat will go forward like autumn-sown. If no rye has been sown for fodder for dairy cows, &c., April wheat should now be put in for that purpose, as it will come nearly as forward as autumn-sown rye, and prove better fodder because the plant is more leafy; and if not required as fodder it may be cut for straw just as it comes into ear, and straw being very dear it may be very serviceable when the home farm consists for the most part of pasture land. The horses now may cart dung to heap, or from heap to pasture land, or cart earth to form the basis of future heaps of manure for turf land. The labourers should now after heavy rains go, spade in hand, and let off water wherever it is found in the fields, and particularly on the late-sown wheat. They will also be engaged in making-out ditches, plashing hedges, stopping gaps in the quick and other hedges made by hunting and shooting sportsmen. The best way we find to stop gaps is to bring down boughs on either side and tie with tarred yarn or copper wire; one year's growth after will effectually stop the gap. It is no use to plant young plants to fill blanks; they never thrive, and it does not look well to use posts and rails.

POULTRY KEEPING.

CAN poultry-keeping be made profitable? We know of no question upon which opinions are more conflicting. One day on our journey to town a suburban resident complains of the scarcity of eggs, that such a thing is never seen on his breakfast table during the winter, and that he believes every one he gets throughout the year costs him 6d. in food. His neighbour tells a very different tale: he finds his fowls very remunerative—they lay well, and summer or winter he is never without the delicate luxury a new-laid egg. Further, he has been fortunate enough to hatch ten chickens early in March; they all lived and did well. Four of them, however, turned out to be cocks, and had been transferred from the poultry run to the table, the most delicious fowls he had ever tasted. The other six pullets were now in full lay, and had kept him well supplied with eggs since Michaelmas. Upon further inquiry we found our first informant had not been more fortunate in rearing chickens than he had been with his eggs. The hen he sat in March had most annoyingly deserted her nest; a second was tried in April, but she was so clumsy she contrived to break five of the eggs; two did not hatch, and one was such a bad mother only one miserable little object was alive out of the five she did bring off. The cases we have quoted are not exaggerated; similar results and diversities of opinion we hear daily. We quite believe them, and often from our own knowledge of the people expect them, but who but those who from experience know the necessities of fowls can reconcile them? Accidents happen and failures sometimes occur with the most careful, but we are convinced the cause of failure which poultry-keepers assign to so many causes, bad luck coming in for a large share, too often is occasioned by neglect and rests with the disappointed ones themselves. Fowls, it must be remembered, are not playthings and, like children's dolls, to be made the all-engrossing amusement of an hour and then left to the tender mercies of an overworked general servant or cook. No matter if fowls are kept for egg-producing, for the table, or reared for the exhibition pen, certain essentials must be provided for their shelter, and an amount of regular attention given to their natural wants. They cannot be treated like the Irishman's pig that was alternately starved and fed to get the bacon streaky. A week's nursing cannot make up for a day's neglect. It is better to feed once

a-day with regularity than three times with occasional omissions. The fowls would thrive better; and apart from the question of profit, it is so much more satisfactory to look at a nice pen of healthy fowls with their blood-red combs than the pale sickly-looking wretches we find in some of those neglected aviaries. We think the "Ingoldsby" author must have had one of those miserable occupants before him when he wrote the effect of the cardinal's curse upon the jackdaw—

"On crumpled claw
Comes limping a poor little lame jackdaw;
No longer gay as on yesterday,
His feathers all seemed to be turned the wrong way:
His pinions drooped; he could hardly stand;
His head was as bald as the palm of your hand;
His eye so dim, so wasted each limb,
That, heedless of grammar, they all cried 'That's him!'"

Fowls to be profitable must be fed with regularity, and in future numbers we shall give a few brief suggestions upon this subject; but to those who are dreaming that something or other will improve their prospects of success during the ensuing season, we warn them their dreams will not be realised without regular attention. The new year generally suggests a new point of departure in the affairs of life, so we would most sincerely advise all who have so signally failed in poultry-keeping to take this opportunity for a fresh start, and to remember past failures only for the purpose of profiting by the experience, and to believe that, whether they rear fowls for the table or for exhibition, the fault will rest principally with themselves if they are not successful.

POULTRY IN 1877.

(Continued from page 39.)

WE have often wondered why the Spanish fancy does not increase. At one time we were inclined to think that this arose from a few old and experienced breeders keeping up stocks which it was almost impossible to beat. Many of them have, however, now retired, and those who continue to exhibit do so for the most part at the great shows, and do not, like some other fanciers, send all over the country for every 15s. prize. We now believe that it is in some measure due to the unfortunate trimming of the face. It was our own lot to choose Spanish as our first exhibition breed, and after we had for two or three years bred carefully from excellent specimens, and produced birds which subsequently in other hands carried all before them, we never so much as won a high commendation, simply because we were perfectly ignorant of the modes in which faces are got up. In disgust we abandoned them for other breeds, and we know that others have done the same. Either this improvement of the face for exhibition should be a recognised thing like the grooming of horses, or it should be put down. We hope the new Poultry Club will take the matter into its consideration. We should like to see texture and shape of face taken into consideration by judges more than its mere size. So enormous has become the development of face in some strains that hens are produced which might be mistaken for cocks, while the inside of the cocks' gills is white like the face. Bristol is still the head quarters of Spanish, though the breed is not there distributed as formerly, but most of the best specimens that we have seen during the past year have come from the yard of Mr. E. Jones. We commend the breed to anyone wishing to start a fresh variety. At many of the early chicken shows there is little competition in it. At Ipswich a cup and six prizes were offered, while only one bird was to be found that could possibly have been noticed at a good show.

The Pencilled and Spangled varieties of Hamburgs retain their old popularity in the north, but we regret they are not more fancied in the south, so hardly do we find them with a free range, always bright and active, moulting in the shortest space of time, and all the rest of the year in good trim. Now and then a fine specimen is produced in the south, as the Golden-pencilled cockerel at the Crystal Palace Show, but it is generally at once snapped-up at any price by one of the northern breeders. We fear that many are prevented like ourselves from showing them more extensively on account of the unscrupulous way in which their combs are cut and carved for exhibition, and what is far worse, the barefaced manner in which some judges select these doctored birds for the highest honours. The Black variety has attained a very high point of excellence both in form and glossy-green sheen. Some of those shown by the Rev. W. S. Serjeantson during the past season appeared to us as near perfection as possible. The classes are well filled, and to win in them is indeed a high honour.

The different French breeds seem to have found their level. Without the immense numbers being shown that for a year or two made their appearance, a good prize list will always command well-filled classes of Crèves and Houdans. The former have been particularly good in 1877, fine crests being shown combined with great size. We are glad to see some of their admirers showing birds with shorter legs. A fine round breast and short legs are, in our opinion, great merits in a Crève. Houdans have not progressed of late. The show of them at the Crystal Palace was not

first-rate. Crooked legs seem a prevalent fault in them; still they are found a thoroughly useful fowl, and we see them in many a small back yard where just a few fowls are kept for eggs. La Flèche have been found unsuited to the English climate and become fewer and fewer.

We should like to see a large addition to the practical admirers of Polish. Practical we say, for nearly everyone admires them when seen, though few cultivate them. They are admirably adapted to the many who keep a few birds for laying at the end of a suburban villa garden, so tame, interesting, and contented are they. Provided only their whole run is covered over and nicely sanded or gravelled they will keep healthy in a very small space, seldom attempt to fly, and when occasionally let out on a fine day to run on a lawn or meadow are a charming sight. The very circumstances which are of the greatest advantage to most breeds—viz., a large and free range, are positively detrimental to Polands, for their crests become wet and matted in rain or wet grass, they lose their way, and catch colds.

In the "Poultry Book" we find ten varieties as then existing, but only three are now shown. It is a pity that no one now, as Mr. Vivian seems to have done twenty-five years ago, makes a collection of all the procurable varieties. We have ourselves seen a pair of Cuckoos and several Buffs within the last few years at shows, though none in 1877. Only last spring we saw a handsome Cuckoo in the Jardin d'Acclimatation at Paris, and some pure Whites in Italian farmyards. Of the kinds now shown the White-crested Blacks are at present as good as any we have ever seen. The Silver and Golden birds have prodigious crests, though often unshapely ones, and we fear that crest carries too much weight in the show pen, for one seldom sees well-marked birds, most of them being neither spangled nor laced.

Malays can never be a really popular breed, but their old admirers stick to them, and when they are well classified a fair entry is always found. Andalusians have improved; their lovely soft colours and useful qualities should indeed make them favourites. To the energy of Miss Arnold is, we believe, due much of their advance in beauty and favour. At the Crystal Palace they struck us as by far the best collection of the breed we had ever seen. Leghorns are becoming widely distributed, thanks to the enterprising "Leghorn Club," and the ugly yellow earlobes which are so much disliked seem disappearing. Silkies are less cultivated than they should be, and we regretted to find them without a class at the Crystal Palace Show. Those shown where classes were given to them were probably the nearest perfect specimens as to all the points desired yet seen. Every rearer of Game or of the more delicate varieties of poultry should keep them as nurses.

The Variety classes have had few startling additions of late. The curious Aseel fowl, or Indian fighting Game cock, has here and there been shown, and has hardly received its due. Through the liberality of Mr. Dutton it is likely to become less rare in this country.

In Bantams the Game varieties have, as of late years, generally been up to a high standard, though by no means so numerous as eight or ten years ago. Black Rose-combed are as popular as ever. We fear beauty of carriage and fineness of sickles in the cocks is often sacrificed to mere smallness. Whites are at a low ebb. Even blue-legged birds have been seen in the prize list. Will no one take up the variety? Some excellent Sebrights, chiefly Silvers, have come out in the past year. Even Mr. Leno has at times been vanquished. The little Pekins are, we believe, now confined to two yards. Some of the best Japanese ever known have appeared, one of the results of Mr. Brassey's interesting voyage in the *Sunbeam*.

Ducks in 1877 call for little observation. The magnificent new Pekin Ducks promise to be a most useful addition to our poultry yards. At Oxford a class was given to them for the first time, and no less than eighteen pairs appeared. The old Embden Goose seems disappearing before the Toulouse, but two pairs of them were entered at Birmingham.

The Turkeys of the present day are certainly a great advance on those of a few years back. The magnificent glow of colouring on many of the cocks and their reddish tinge on the legs shows that the best strains are indebted to crosses with American birds. A year ago we were forced to comment severely on the constant showing of old Turkeys in the classes for young ones. In the year 1877 we were pleased to observe a marked improvement in this matter.

Such is our cursory review of poultry in 1877. The year 1878 promises in its first days to begin in a more seasonable manner than some of its later predecessors. We trust for the poultry fancier's as well as for others' sake that it may so go on, and that winter may precede and not follow a balmy spring. We may then hope in due time to hear of an excellent hatching season, and later on to see abundant chickens both on the table and in the show pen.—C.

THE BORDER COUNTIES SHOW OF POULTRY, &c.

THIS Show was held at Carlisle from the 10th to the 12th inst., and was in all respects a success. The entries amounted to

about 1100. The hall is a grand one for the purpose, although in the cases where the pens were arranged near the walls under the gallery (as in the case of the Game and Game Bantams) the light was not good. Turner's pens were used on this occasion.

Game were poor as classes in Black Reds, though there were some good birds included in the list; but the Brown Reds were good in all classes, both the cups going to that variety. *Dorkings*, especially the Silver-Greys, were very good, and the cup rightly placed on the latter variety. In *Brahmas* the cup was awarded to an old Dark cock, and in *Cochins* to a White cock. *Hamburghs* were very good, and the cup went to Gold-pencilled. *Houdans* were very large classes, and some excellent birds were shown, not alone in size and marking but also in that much-neglected point the comb, although several capital pens were left out for scaly legs and feet, a disease very easily cured. Black *Spanish* a small lot, but very good. The Variety class was a good one, comprised of Polish, Black *Hamburghs*, Scotch Greys, &c., and the cup for this section was given to the first-prize pair of Silver Polish. The coveted sewing machine was carried off by a perfect pen of Black *Hamburghs* in the Selling class out of an entry of ninety-three. *Bantams* were very good entries, but the Black Red cocks were badly placed for light, and so good was the quality that most of the pens were noticed, the cup for Game Bantam cocks being awarded here to a very stylish cockerel. In the next class *Piles* won all the prizes, Mr. Addie's, late Brownlie's, champion being first, closely pressed with two beauties. Hens (Black Reds) were not so good as a class as we expected, but the winners were very good; but the cup for hens went to the next class for the best Duckwing pullet we remember. Black Rose-combed were the best class of that variety we have ever seen, and the cup for these and the next class was awarded here. Variety class.—First White Rose-combed, second Pekin, and third White-tooted. There were some Sebrights, but these were generally too large.

In *Pigeons* *Pouters* headed the list. In cocks a large White was first and a Blue second, the third being Red. Hens were by far the best. First a Blue, second White, and third a Yellow. In *Carriers* the winners were very good in both classes. The first-prize hen a very heavy well-wattled Black. In *Barbs* a Black hen was placed first, second a Black cock very pale in eye, and third a Dun. Short-faced *Tumblers* were a grand class, as may be seen by the list. First was a grand all-round Almond cock, second a hen, and third a grand-headed Kite. In Long-faced *Tumblers* first was a nice Yellow Mottle, very bright in colour; second a Black Bald cock; and third a Red Mottle. *Fantails* were a very good class; first and second White, and third Blue; the first a real Scotch Fancy, with perfect circular tail. *Jacobins* were the very best class we ever saw, and the competition uncommonly close. A very small well-hooded Red hen first, a Red cock of grand all-round properties second, and a very small Red hen third, and almost every pen noticed. *Turbits* were very good, the whole of the winners Blues. *Owls* poor except the winners. First a champion Blue English, and second and third Foreign Whites. *Antwerps* a poor entry, but the birds good; the same remarks applying to the *Dragoons*. *Magpies*.—First Red, second and third the smallest of small Blacks. *Archangels* were very good in colour and points.

In *Cage Birds* the nervous-looking but graceful Scotch *Fancy* headed the list with Clear and Marked classes, the first-named being by far the best and containing some of the best Yellow birds we have ever seen, combining shape and style with carriage and colour. Yellow *Norwich* were very good and well shown, but the best of these was the first-prize Buff. Crested *Norwich* were only good as regards the winners. The first, a grand light marked bird with splendid crest, was rather dirty. The Variety class was a puzzle, so good were the birds shown. The first was, however, given to a capital Belgian, second to a perfect Lizard, and third to a good Belgian. In *Mules* there were some grand ones. First in Yellow Goldfinch was almost clear but slightly ticked, large and good in plumage; second a four-pointed one, the extra prize going to a Clear Buff, large and grand in all points. In the Variety class first was a nice bird, but not as large as we have seen from a Goldfinch and Bullfinch; and second and third Buff *Linnets*. Goldfinches and Bullfinches were both grand classes, but *Linnets* poor except the first-prize bird.

POULTRY.—GAME.—Black Red.—Cock—1, J. Brough. 2, J. Bell. 3, S. Matthews. *etc.* E. Winwood. Cockerel—1, J. Brough. 2, J. Reddick. 3, E. Winwood. Hen—1, Walsh & Walker. 2, S. Matthews. 3, T. Bellman. BROWN RED.—Cock—1, Cup, and Special, C. W. Brierley. 2, J. A. Mather. 3, T. Raines. Cockerel—1, A. Cameron. 2, Riley & Cooper. 3, W. & H. Adams. Hen—1 and Cup, W. & A. F. Fenwick. 2, T. Parker. 3, S. Matthews. *etc.* W. Rudd. Any other variety.—Cock or Cockerel—1, S. Matthews. 2, W. & H. Adams. 3, H. A. Clark. Hen—1, J. F. Crowther. 2, T. Bellman. 3, C. W. Brierley. DORKING.—Cock—1 and Cup, W. Wallace. 2, Mrs. Whitwell. 3, Capt. G. F. Lyon. *etc.* J. Cunningham. Hen—1, Capt. G. F. Lyon. 2, J. Holaday. 3, J. Cunningham. Any other variety.—Cock—1, H. Stevens. 2, F. Suowden. 3, A. Paisley. *etc.* A. Mitter. Hen—1, J. Walker. 2, T. Briden. 3, J. Copple. *etc.* H. Beldon. BRAHMA FOOTRA.—Light.—Cock—1 and 3, J. & W. Birch. 2, J. F. Smith. Hen—1 and 3, J. & W. Birch. 2, J. F. Smith. *etc.* T. A. Dean. Duff.—Cock—1 and Cup, J. F. Smith. 2, J. Walker. 3, R. Hargreaves. *etc.* Dr. J. Macrae. Hen—1 and 3, J. Sandeman. 2, J. Walker. COCHIN-CHINA.—Cinnamon Buff.—Cock—1, J. Walker. 2, A. Bamford. 3, G. H. Proctor. *etc.* T. Wagh. Hen—1 and 3, J. Walker. 2, J. Wood. Any other variety.—Cock—1, Cup, and 2, A. E. W. Darby. 3, J. Wood. Hen—1, A. E. W. Darby. 2, Mrs. W. Steven. 3, A. Bamford. HAMBURGH.—Golden-spangled—1 and 3, G. and J. Duckworth. 2, J. Rawnsley. Silver-spangled—1, 2, and 3, J. Rawnsley.

Golden-pencilled.—1 and Cup, G. & W. Duckworth. 2 and 3, J. Rawnsley. *etc.* W. Park. *Silver-pencilled*.—1, H. Beldon. 2, H. Pickles. 3, J. Rawnsley. *HOUDANS*.—1, J. Robinson, jun. 2, W. Wright. 3, R. B. Wood. *etc.* J. & R. Martindale. *Chickens*.—1, B. W. Thomas. 2, A. Wither. 3, Mrs. Vallance. *etc.* Dr. J. Macrae. R. B. Wood, J. Graham. *SPANISH—Black*.—1, J. Norval. 2, W. R. Bull. 3, J. Thresh. *etc.* H. Wilkinson. *ANY OTHER VARIETY EXCEPT BANTAMS*.—1 and Cup, H. Beldon. 2, C. F. Copeman. 3, J. Rawnsley. *etc.* R. Beed. W. Girdwood. A. & W. H. Silvester. J. & A. Laird. *SELLING CLASS*.—1, S. Garnett. 2, W. A. H. Fenwick. 3, H. Beldon. 4, J. Wilkinson. 5, J. Cople. *etc.* J. Walker. G. & J. Duckworth. H. Yardley. A. & W. H. Silvester. *GAMES BANTAMS—Black or Brown Red—Cock*.—1 and Cup, E. Walton. 2, G. Brough. 3, W. Harrison. *etc.* G. Davie. E. Walton. W. F. Aiddle. Duncan & Kennedy. *Hen*.—1, G. Coulthard. 2, W. F. Aiddle. 3, E. Barker. *etc.* G. Brough. J. Nelson. W. Rudd. *Duckwing or Pile*.—1, W. F. Aiddle. 2, G. Coulthard. 3, J. Dixon. *etc.* R. Brownlie. E. Walton (2). *Any other variety*.—1 and Cup, J. Nelson. 2, G. Coulthard. 3, R. Brownlie. *etc.* E. Walton. G. Coulthard. *BANTAMS OTHER THAN GAME—Black Rosecomb*.—1 and Cup, J. W. Crowther. 2, W. H. Shaeckleton. 3, E. Walton. *etc.* H. Beldon. H. W. & H. King. W. R. Henderson. *Any other variety*.—1, J. W. Crowther. 2, H. H. Smith. 3, J. Brigham, jun. *etc.* J. Walker. A. B. Ferguson. H. W. & H. King. *DUCKS—Rouen*.—1 and Cup, J. Walker. 2, F. C. S. Rawson. 3, Mrs. T. Lamb. *Any other variety*.—1, J. Walker. 2, A. & W. H. Silvester. 3, T. Blaylock. *etc.* J. Walker. R. Mann. H. B. Smith. Mrs. F. Grant.

PIGEONS—Pouter.—Cock. 1, J. & W. Towerson. 2, A. & R. Hutchinson. 3, T. Steel. *Hen*.—1, A. & R. Hutchinson. 2 and 3, H. R. Teeney. *CARRIERS—Cock*.—1, J. Walker. 2, H. Yardley. 3, J. & W. Towerson. *Hen*.—1, J. Booth. 2, J. Walker. 3, H. Yardley. *BABBS*.—1, W. Harrison. 2, J. Thresh. 3, H. Yardley. *TUMBLERS—Short-faced*.—1 and 2, H. Yardley. 3, W. Brydone. *etc.* J. Coupland. W. Brydone. *Long-faced*.—1, H. Yardley. 2, J. Thresh. 3, J. Wilson. *etc.* C. F. Copeman. H. Yardley. *JACOBS*.—1, W. Harrison. 2, W. and R. Davidson. 3, E. Norman. *etc.* T. Holt (2). A. Leith. *PANTAILS*.—1, J. Watara. 2, J. F. Loversidge. 3, H. Yardley. *TURBITS*.—1, W. Harrison. 2, J. Taylor. 3, W. Brydone. *OWLS*.—1, A. Duthie. 2, J. Booth. 3, H. Yardley. *etc.* W. A. Fishburn. E. Norman. *ANTWERPS*.—1 and *etc.* H. Yardley. 2, H. Rawnsley. 3, J. Booth. *DRAGONS*.—1, J. Booth. 2, H. Beldon. 3, A. Leith. *MAGPIES*.—1, H. Beldon. 2, H. W. Webb. 3, H. Jacob. *ARCHANGELS*.—1 and *etc.* H. W. Webb. 2, J. Cowe. 3, H. Jacob. *ANY OTHER VARIETY*.—1, W. Brydone. 2, H. Yardley. 3, H. Beldon. *etc.* W. Mann. H. Yardley. W. Brydone. W. & J. Towerson. J. Williamson. *SELLING CLASS*.—1, J. Williamson. 2, H. Beldon. 3, E. D. Carless. *etc.* E. Norman. J. Williamson.

CAGE BIRDS—SCOTCH FANCY—Yellow or Buff.—1, 2, and Extra, J. Thorpe. 3, J. Lightfoot. *etc.* J. Grant. W. Veltch. J. Vose. Mrs. A. Jardine. R. Anderson. J. Hamilton. *SCOTCH FLECKED—Yellow or Buff*.—1, J. Thorpe. 2, D. Tweedie. *etc.* J. Armstrong. J. McVittie. J. Thorpe. *NORWICH—Yellow*.—1, Stevens & Tenniswood. 2, J. J. Reeson. 3, Extra. Stevens and Tenniswood. 2, C. Nevill. *Variegated Yellow or Buff*.—1 and Extra, R. Atkinson. 2, J. Reeson. *Crested Yellow or Buff*.—1, F. Knaggs. 2 and *etc.* R. Atkinson. *ANY OTHER VARIETY CANARY*.—1 and Extra, J. Alderson. 2, Stevens & Tenniswood. 3, R. Atkinson. *etc.* T. Graham. J. Ruddick. J. Armstrong (2). R. Atkinson. *MULES—Yellow*.—1, Stevens & Tenniswood. 2, A. Young. *Buff*.—1 and Extra, J. Reeson. 2, W. T. Armstrong. *etc.* T. Wilson. Miss M. Duncan. C. Nevill. A. Young. *Any other variety*.—1, T. Drake. 2 and *etc.* Stevens & Tenniswood. 3, C. Kevin. *GOLDFINCH*.—1, R. Pearson. 2, J. Thorpe. 3, J. Richardson. *BULFINCH*.—1 and Extra, R. Anderson. 2, R. Pearson. *etc.* R. Atkinson. *LINNETS*.—1, Extra, and *etc.* R. Pearson. Stevens & Tenniswood. *LARKS*.—1 and Extra, Master F. Coulthard. 2, W. T. Armstrong. *ANY OTHER VARIETY OF NATIVE BIRD*.—1 and Extra, W. T. Armstrong. 2, J. McVittie. *FOREIGN BIRDS*.—1, R. Ward. 2, R. Pearson. *etc.* T. Drake. R. Sutherland. *SELLING CLASS*.—1, W. Burniston. 2, Stevens & Tenniswood. 3, W. T. Armstrong. *SINGING CANARY OR MULE*.—1, J. Robinson. 2, J. Robinson.

JUDGES—Poultry, except Bantams: Mr. R. Teebay, Preston. *Bantams, Cage Birds, and Pigeons*: Mr. E. Hutton, Pudsey, Leeds.

NATIONAL PERISTERONIC SOCIETY.

A VISIT to the annual Show of this Society is not only interesting and pleasurable but profitable to the critical fancier, for it is here that he sees at a glance the state of the fancy as it exists among the principal columbarians of England, perhaps more especially the southern part of it. Here it is he can draw comparisons with the by-gones and the present, and can somewhat speculate on the future, and there is much to meet the eye of the keen observer as regards the bias of certain breeders for particular forms and types of the same variety. Perhaps in no case is this more observable than in that of Dragon. Here, according to the pens of birds shown, seems to exist a vast difference of opinion, one exhibiting a pen of decidedly very heavy-wattled birds, and what the old Dragon fancier proper would call Horsemen and not true to anything, while another rushes off into the opposite extreme with a pen of spindle-beaked birds, which are but a slight remove from what is known by the name of "Skinnum." Now to my mind the best type of the true Dragon was to be found in the pen shown by Mr. Tegetmeier. I allude to the birds with the stout beaks, with thin, close, compact wattles, that of the eye being of a blue tint like the colour of the bird itself. Mr. Whitehead also had some birds which he evidently was trying to breed-up to this standard, for standard it is of the true Dragon. Mr. Shaw's Yellow hen amongst Yellows was well worthy of study, but the majority of the birds of this colour carried far too much eye-wattle and of the wrong colour, while others led-off in the direction of the Scanderoon with their down-hooked beaks, while the Whites left but little doubt of their origin. How it startles the old fancier to hear £20 offered for a Blue Dragon and refused. Yet such was the case with one of Mr. Tegetmeier's birds. Space to-day precludes my finishing my remarks on this excellent and instructive exhibition, but I hope to resume the task on an early date.—HARRISON WEIR.

VARIETIES.

ONE of the most disagreeable pests to the sitting hen and to chicks is lice. The nest should be well sprinkled with carbolic powder, but where it will not come in contact with the eggs when the chicks are first hatched, rub sulphur and lard, well mixed, on the poll of the head, under the wings, but more par-

ticularly around the vent. I suppose this location is chosen for their carnivals, for they congregate in large numbers, but sulphur and lard have the desired effect. Some have used kerosene with success, others to their sorrow.—A.

THE General Steam Navigation Company has been fined £20 for cruelty to animals imported from the Continent. Only those who are in the habit of making the journey between London and Antwerp or Rotterdam can form the smallest idea of the atrocities to which the unhappy creatures who are brought over by the vessels of this Company are subjected. I made the journey one stormy night in company with 1828 sheep, piled one on the top of another like herrings in a barrel. The stench throughout the night was overwhelming, and the spectacle when the "Leo" arrived at Miller's Wharf is never to be forgotten.—(The Tatler).

"M. C." COMMUNICATES to *Land and Water* the following facts about milk.—It has been discovered from chemical analysis that the evening's milk is richer than morning's. Professor Boedeker has analysed the milk of a healthy cow at different periods of the day, and found that the solids of the evening's milk (18 per cent.) exceeded those of the morning's milk (10 per cent.) while the water contained in the fluid was diminished from 89 per cent. to 86 per cent. The fatty matter gradually increases as the day progresses. In the morning it amounts to 2½ per cent., at noon 8½ per cent., and in the evening 5½ per cent. The practical importance of this discovery is at once apparent, inasmuch as it develops the fact that while 16 ozs. of morning milk will yield but ½ oz. of butter, about double the quantity can be obtained from the evening's milk. The casein is also increased in the evening's milk from 2½ to 2½ per cent., but the albumen is diminished from 44-100ths per cent. to 31-100ths per cent. Sugar is least abundant at midnight (4½ per cent.) and most plentiful at noon (4½ per cent.) The per-centage of the salt undergoes almost no change at any time of the day.

A CORRESPONDENT writing in the *Agricultural Gazette* on whole r. pulped roots states that our predecessors gave far too many turnips in a day to fattening oxen is certain. That pulping roots is excellent husbandry in some cases is equally certain. But none the less it is true that, to give the finish to a full-grown bullock, a few white turnips given whole (in their season) is the best method of employing the turnips. The animal seems to get all the juice so, unaltered by the air or by the knives; and the turnips, used salad fashion (and white turnips should be consumed for such animals more as salad than as anything else), clean the mouth, provoke saliva, and create an appetite for the meal, cake, hay, &c., which are the real providers of the finishing fat. At all events, besides the famous authority at Tillyfour, and Mr. Read, several first-rate feeders to my knowledge have reverted to the old plan, in October and November, with their Christmas beasts, and believe themselves to be justified by the result. When swedes come on they are sliced. Yet this is not written to disparage the pulpers in their proper place.

A CORRESPONDENT in admitting the usefulness of the "simple chicken coop," figured on page 39, remarks that in the case of casks hooped with iron it would not be easy to divide the barrels longitudinally without first removing the hoops. This, he says, may be done, and the casks may be prevented falling to pieces by affixing a couple of wooden hoops inside the barrels to which the several parts can be tacked. The casks can then be divided, and permanent half-circular hoops of iron can be placed on the outside for making them firm and strong.

WARM FOOD FOR CATTLE.—Thirty years of experience in this matter has convinced one and all on my farm of its advantage. We usually had forty, and often many more head of cattle, young and old. A closed tank of water was heated by the waste steam, and as the lad or feeder mixed the cut chaff, bran, malt, or cake in the iron tubs sunk level with the floor, an occasional pail of this hot water was thrown on the mass, layer by layer, until it was piled high above the rim. The waste steam passing around these iron tubs kept their contents hot. After a few hours the reeking mess was carried to, and spread over, and mixed with the pulped roots, and then placed in the bullock mangers. We could never fat animals so quickly as by these means. It is a decidedly paying operation.—J. J. MECH.

FOOD FROM ABROAD.—Last year the amount paid to foreign nations for corn, cattle, and meat was £96,879,737, to contrast with £87,129,886 in 1876. For live stock the sum disbursed was, in 1877, £6,015,690, as against £7,260,303 in the preceding year. The items for fresh meat were much larger, consequent upon the shipments from America and Canada of quantities of beef and carcasses of mutton. The total sum paid for foreign stock alive and dead was, in 1877, £17,813,674; in 1876 it amounted to £19,030,455. For corn last year the sum paid was £68,192,224; in 1876, £61,584,648. Butter cost in 1877, £9,538,305; cheese, £4,768,053; and eggs, £2,472,481, to be compared respectively with £9,702,624, £4,251,428, and £2,610,281.

A CORRESPONDENT of the *Ohio Farmer* gives the egg-producing capacity and weight per dozen of eggs of various kinds of fowls, as they came under his notice, as follows: Light Brahmas

and Partridge Cochins, eggs seven to the pound lay 180 per annum. Dark Brahmas, eggs eight to the pound, lay 120 per annum. Black, White, and Buff Cochins, eggs eight to the pound, lay 115 per annum. Plymouth Rocks, eggs eight to the pound, lay 150 per annum. Houdans, eggs eight to the pound, lay 160 per annum. La Flèche, eggs seven to the pound, lay 180 per annum. Crève Coeurs, eggs eight to the pound, lay 140 per annum. Black Spanish, eggs seven to the pound, lay 140 per annum. Leghorns, eggs eight to the pound, lay 160 per annum. Hamburgs, eggs nine to the pound, lay 150 per annum. Polish, eggs nine to the pound, lay 125 per annum. Dominiques, eggs nine to the pound, lay 185 per annum. Game, eggs nine to the pound, lay 180 per annum. Bantams, eggs sixteen to the pound, lay 90 per annum.

WARMTH AND VENTILATION.

In a cold and variable climate like ours bee life is one of suffering during the winter months. In frosty weather bees are in the "arctic regions" without the least hope of finding a short north-western passage. In prospect of spending a winter in the Arctic seas our sailors are provided with the warmest possible clothing and heat-generating food. In cold climates human beings require food with much carbon in it to keep up the heat of their bodies, and clothes to keep it in after it is produced. Nature, in the case of animals of various kinds, covers them with hair, and wool, and feathers on the approach of cold weather. The All-wise Creator covers them with good warm coats. Bees left to themselves in this country seek protection. Fugitive swarms seek and generally find shelter in human dwellings or in trunks of old trees. Bees are little fragile creatures, and while placed under artificial treatment and are in the hands of men they should be well protected. All hives in this country should be well covered from November till April. If I were asked what covering I would prefer for a hive in winter I would say a large woolly sheep's skin turned inside out and tied closely round the hive. But sheep's skins are too dear for this work, and we have to look out for old carpets and matting, hay, straw, and old newspapers. A good straw covering outside and an inside stuffing of soft dry grass 8 inches thick make a warm protection for a hive. All winter coverings should be left on till April that early spring breeding be not hindered.

Ventilation is another phase of bee-keeping that has not been fully considered. The ventilation of human dwellings is now receiving more attention than formerly. The last published great work on chemistry by Professor Roscoe and his assistant in Owen's College treats largely on the importance of proper ventilation in houses. Our best pine and grape-growers attach great importance to the admission of fresh air to their pineries and vineries. In bee-culture the same principle holds good; both warmth and ventilation are necessary. No one can say what amount of fresh air is needed in a bee hive. In hives properly constructed or made of proper materials the bees have the power of regulating the supply to a certain extent. For instance, if straw hives are too softly made or loosely sewed the bees use a good deal of propolis for daubing or plastering the insides of their hives. In hives properly made they use very little propolis. Hives here that have been filled and emptied many times, or used for many years, have scarcely received a touch of propolis; and I have seen a hive so firmly and closely sewed that it did not let the moisture of the bees escape; the moisture ran down its sides as it does in wooden hives. The question of ventilation of hives will yet have more attention from our friends of the bar-frame school. My powers of invention are not great, otherwise I might produce a bar-frame and get a patent for it. Some two or three years ago I visited the apiary of a Cheshire gentleman who had just begun to keep bees. He showed me a bar-frame hive which he had just made. It was a model hive for neatness and appearance; it was perfect, too, so far as ventilation goes. Two holes about 8 or 9 inches square were made in the sides of the hive and neatly covered with Indian matting—I think it is called by that name, and is often used in lining and decorating the summer-houses of English gardens. If bar-frame hives be made large enough after the pattern I have been trying to describe—viz., with large spaces in their sides cut out and covered with proper matting inside and out, with soft dry hay between the matting, they will for health and excellence surpass all the hives yet produced by the bar-frame school, and, so far as ventilation goes, be on a par with straw hives. I commend this suggestion to the consideration of hive-makers, and the consideration of warmth and ventilation to all bee-keepers.—A. PETTIGREW.

OUR LETTER BOX.

ARTIFICIAL HATCHING (M. A.).—No incubator yet invented has proved satisfactory. The temperature required for hatching is about 105°.

FEEDING FOWLS (E. L. P.).—The cause of the fowls being thin is that they have been very fat and are diseased. Disease with them, as with other animals, shows itself by loss of appetite. The feeding has probably had nothing to do with the laying. You cannot expect winter laying from hens; it is against nature. The pullets should lay, but if a few eggs are produced

you must be satisfied. The writer of this has hundreds of pullets, and does not average daily seven eggs per hundred pullets. The numbers will now increase. To come back to feeding. If you have no one you can trust you must act yourself for a few days. Spite of their thinness we advise you to keep them very short of food for a few days, then have a small quantity of ground food (oats or barley) mixed and feed yourself. Leave off as soon as they seem careless about it. At midday let them have some maize or barley, and ground food again in the evening. There is no yard without waste, and it arises from food lying about. Two days' feeding will show you the quantity they consume. Let that rule the supply. You will soon find out the economy of it, and your birds will do better. Nothing is more difficult than to name the quantity of food a number of fowls should consume. It requires to know the nature of their run and the amount and quality of the food it affords. A gravel run, however extensive it may be, affords no food, while one of half the extent, but of grass, will supply many indispensable meals. Again, it must be known what the previous feeding has been. Fowls that have been kept on short commons will for a time eat voraciously, and then settle down to a fair average. We advise you to give no whole corn, except a feed of maize at midday. Let your other feeding be of ground oats or barley meal slaked with water, and given morning and evening. We have never done good with Indian meal; our fowls would not eat it. They eat it whole readily, and its effect is (different from your experience) to make everything very fat. This fat disappears before the fire, and the lean acquires many of the properties of Indian rubber so far as eating is concerned. Give the scraps as part of the daily food, and not in addition to it.

BIRD SHOW (Inquirer).—We understand that there is to be a Show at the Alexandra Park. Wait until you see it is advertised.

BEE BOOK (A Beginner).—Pettigrew's "Handy Book of Bees" is published by Blackwood & Sons, price 3s. 6d.

REMARKS.

- 9th.—Cold morning but fine; rain at night.
 10th.—Very fine bright day, damp in early part of evening, but fine moon-light night.
 11th.—Fine frosty morning, after part of the day rather dull.
 12th.—Sharp frost till night, cold and dull day.
 13th.—Warmer, overcast, and dull, with a little rain at intervals.
 14th.—Fine but not bright day, warm in afternoon and evening.
 15th.—Fine early, and variable during the day, slight showers, bright sun, fine sunset, and cloudy evening.
 Owing to a moderate frost on the 11th and 12th the temperature is rather lower than in the previous week, in spite of the high temperature of the 16th. Very little rain.—G. J. SIMONS.

COVENT GARDEN MARKET.—JANUARY 16.

We are now quite without either English or French Pears, our supply being entirely drawn from California. Some fine specimens of Easter Beurre having reached us since Christmas, though the bulk have arrived in bad condition owing to the mild weather they have come through. Apples are short; good samples being in request, especially Blenheim. Late Grapes appear to be keeping badly, consequently the supply is in excess of the demand, and prices low. Kent Cobs are in fair request.

From observations taken near London during forty-three years, the average day temperature of the week is 47.9°; and its night temperature 31.9°.

VEGETABLE CULTURE.

CHAPTER IV.—THE CAULIFLOWER.

ALTHOUGH the date of the introduction of the Cauliflower into this country does not appear to be exactly known, most authorities agree that it was brought from Cyprus to England about the end of the sixteenth century. However, be this as it may, it is now one of the most esteemed vegetables we possess; and although the natural season of maturing its produce only extends from June until November, Broccoli, which resembles it so much as only to appear different in name, may be grown to give a supply of heads during every month of the year.

Cauliflower plants to produce the earliest heads in June may be raised in two ways. The first and most generally adopted way is to sow the seed in the open ground in August. The piece of ground selected for the seed bed should be in the most genial part of the garden. As early vegetables are cleared off the south border by this time, a position there is as good as any. When the soil is poor a little light manure should be spread over the surface before turning over the ground with the spade. When the weather is dry immediately after digging form a bed, say 4 feet wide and 12 feet long, or larger or smaller according to the number of plants required, and sow the seed before the damp soil turned to the surface has had time to dry. The surface of the bed should be broken fine with a rake previous to sowing the seed, and the seed may either be sown in rows 6 inches apart or broadcast; we prefer the latter. Sow the seed thinly and cover it over with half an inch of fine soil, which may be gathered from round about the bed. When the weather is very hot a mat or some old piece of canvas should be laid over the bed during the day and removed at night until the young plants can be seen coming through the ground, when covering must cease; and after this until they are well advanced in growth they should be watered liberally in hot or dry weather. It is important that the seed be sown between the 18th and 28th of August, because if sown earlier than the 18th the plants will become too large for wintering properly, and will either fruit prematurely in autumn or early in spring. When sown later than the 28th the plants, should the autumn prove unfavourable, may suffer by weakness and be very late in producing heads. By the end of September the plants are large enough to transplant in a frame, which they require for protection during the winter. We have wintered them under handlights, but they keep equally well and do not require so much attention when planted in a cold frame. The frame should be filled to within 1 foot from the top with rich soil, and the plants should be lifted carefully from the seed bed and dibbled into it 3 inches apart each way. When the weather is good the lights should not be put on during October. It is a common error to protect young Cauliflower plants in autumn before there is any actual necessity for it; consequently the plants become tender before the winter has well begun and suffer accord-

ingly. We never cover-up our plants unless the glass is down at the freezing point and during snow or excessive wet, and we never lose a plant. When it is necessary to place on the lights, they should be drawn off again whenever the weather is favourable. When any leaves decay during the winter they should be at once removed. If another frame can be spared, about the beginning of March the plants should be lifted and planted 6 inches apart. When they cannot all be put into a frame the smallest may be put in along the bottom of a south wall. After planting in frames the lights should be kept on for eight or ten days, but remove them again as soon as possible after this, as it is very important that the plants should be quite ready for planting-out in the open air by the end of March.

They should be transplanted to a south border or the most sheltered part of the garden. The soil in which they are planted should be from 18 inches to 2 feet in depth, with plenty of manure placed convenient to the roots. They should not be pulled up with the hand before planting, but each plant should be lifted with a trowel, so as to secure a good ball of soil and roots. They should be put in 18 inches between the plants and 2 feet between the rows. We generally plant a few rows of early Cauliflower between the rows of early Peas, as the stakes of the latter give them good protection. When frost or very cold winds occur, immediately after planting them out a small spruce branch should be placed on each side of every plant, and when enough of 6 or 8-inch pots can be spared, one turned upside down over each plant at night for the first fortnight is of great benefit to them. Thus are the autumn-sown plants brought forward and disposed of in their last quarters, and their only requirement after this is to draw a little soil to the stem of each plant when it becomes about 1 foot high. It may appear as if there was a good deal of attention wanted to bring them to maturity, but they amply repay it. At the same time, however, autumn-sown plants may not be wholly depended on for the earliest planting. Where a little artificial heat is at command in January or February, a box 2 feet square and 4 inches deep should be filled to the depth of 3 inches with rich soil. Sow the seed thinly and cover it with a little more of the soil, and place the box in a temperature of 60°. With a little water the seed will germinate in a week, when the box must be kept near the glass to prevent the plants from drawing. When about 3 inches high they may be taken into a cooler place, and gradually exposed to the air until they can be planted in the frame like the autumn-sown plants. We have had plants raised in this way equally as fine by the end of April as those sown in autumn.

Successional sowings should be made out of doors from the first week in March until the last week in May. In most gardens there is a small piece of ground, generally on a border, set apart to raise the different young vegetable plants from seed; this spot should always be a sheltered one, and the soil should be enriched with decayed leaves, horse droppings, or any other free root-producing substance. Cauliflowers especially delight in this. In preparing to sow the Cauliflower seed a small bed should be formed and the seed sown similar to the directions given for sowing it in

autumn, only in the spring time it is never necessary to protect it from drought. Birds, however, are very troublesome and frequently destroy much of the seed. Two or three pieces of sticks arched over the bed and an old fruit-tree net thrown over them is an effectual protection. Those not having nets may keep the birds off equally well by dusting the surface of the bed with lime, so as to make it quite white, after the seed has been sown. This also prevents snails from eating the young plants, which they are very liable to do. A sowing once a fortnight during the time specified will keep up a succession. As each batch of plants become 5 inches high the largest of them may be drawn out and dibbled in a fresh bed 4 inches apart. When the plants come up thinly it is not necessary to do this, as they may be lifted with good roots from the seed bed and planted in their permanent quarters as soon as they are 6 or 8 inches high.

The principal crops of Cauliflower may be grown in any of the kitchen-garden quarters that have a good depth of soil, moderately strong, and well enriched with manure. It is no use growing Cauliflowers on a poor soil. In beginning to plant, measure the rows off, leaving 2 feet between each; stretch a line from end to end, then take a draw hoe and mark a drill 1½ or 2 inches deep along it; plant the Cauliflowers in this 20 inches apart. It is a great matter to lift the plants with sufficient balls and give them sufficient water to prevent them from drooping down after planting. For the first three weeks or a month after planting they are never safe from snails; these pests nibble strong plants off by the ground in a very short time. Immediately after planting a few handfuls of fresh lime and coal ashes mixed should be spread round the stem of each plant. In wet weather this may be renewed every week. At the same time the plants should be looked over every morning and every snail seen be destroyed. Precautions of this kind will often prevent much annoyance. Ground very full of snails and worms should have a coating of hot lime dug into it before planting any of the Cauliflowers.

As soon as the plants are 10 inches or a foot high the ground should be deeply Dutch-hoed amongst them, and afterwards a good quantity of earth should be drawn to their stems. When the weather is very dry a good watering with liquid manure once a week when the heads are forming assists them greatly. Worms sometimes attack their roots when they are well advanced in growth, which causes the leaves to droop and die. If applied in time a watering with strong lime water will often save the plant. Before the plants are half grown heads no larger than an egg cup often form; this is caused either by the plants being left too long in the seed bed or through poor cultivation. Cauliflower heads should always be cut before they show signs of opening. When there are more heads ready for use than is wanted, they may be kept in good condition on the plants for a week by breaking the leaves half through and turning them over on the head so as to entirely exclude the light. They may also be kept good for a long time by lifting the plants with a ball of soil and placing them closely together in a cool shed or cellar. This plan should always be adopted in autumn when there is any danger of injury from frost.

There are no very serious diseases that affect the Cauliflower. When the plants are young some of them often form little clubs on the base of the stem at the roots; these are caused by a small white grub which is found in the centre of the knob. When the knobs are observed before planting and cut so as to kill the worm the plants will not be injured further by it, and growth will proceed as well as if it never had been touched. After the plants have been planted out and when they are getting a fair size many of them lose their centre, only a few of the outside leaves being left, and although some of them may push a new crown they are never half so fine afterwards. This damage is done by a small insect resembling the Turnip fly. Whenever there is the least appearance of it a small quantity of soot or lime should be thrown with the hand into the centre of each plant; we have found this stop their progress when all else failed.

For general cultivation we depend chiefly on three sorts—viz., Early London, Walcheren, and Veitch's Autumn Giant. No more than these need be grown, as they possess all that is required. A pinch of each of them should be sown in autumn, and they will follow each other in bearing in spring. The three should again be sown in the succession named in spring. After the middle of April the Autumn Giant is the only one that should be sown. Early London comes in earliest,

and produces compact white heads. Walcheren is later, and the heads are a little larger than the first-named. Veitch's Autumn Giant is the finest Cauliflower in cultivation. The heads are immense in size, very hardy and firm, pure white, and excellent in flavour.—A KITCHEN GARDENER.

KEEPING GRAPES—DEW.—No. 2.

REFERENCE was made on page 43 to the extraordinary quantity of water received by the Vine borders at Drumlanrig? At the first glance upwards of 5 feet of rain during the year and 20 inches of this falling in December appears to be inimical to the keeping of Grapes; but when we consider it in connection with the fire heat that must be continually employed we have no reason for assuming the water at the roots excessive. In all probability if the borders were comparatively dry the Grapes would shrivel. Provided the atmosphere of a house is in a right condition a few inches of rain more or less when the Vines are destitute of foliage will not impair the keeping properties of the Grapes. Moisture at the roots is essential for keeping the berries plump, fire heat and a well-managed atmosphere for preventing their decay. Whether does a bunch of Grapes imbibe most water when it is hanging on the Vines, the roots of which are in an outside border, or when it is cut and has its stalk inserted in a bottle of water? I suspect that, however moist the border may be, the bunch derives still more water from the bottle; yet how well do Grapes keep when "bottled" and placed in a suitable room! Mr. Harrison Weir has recorded on page 5 a case where a portion of a crop of Mrs. Pince was cut and "bottled," and the bunches so treated kept their colour, while those remaining on the Vine lost their blackness and changed to a "foxy reddish purple." I have myself cut Mrs. Pince when the berries showed signs of shrivelling and inserted the stems in water, when their plumpness has been restored and has continued for weeks. I once saw two Vines of this variety growing side by side, the roots of one being inside, those of the other outside; the bunches on the Vine in the dry inside border were shrivelled, while those in the wet outside border were plump and smooth. I doubt if the Grapes at Drumlanrig, great as is the rainfall, absorb more water than if they were cut and "bottled."

It is the moisture condensing on the berries that promotes decay. If the dew can be prevented forming on them they will keep. Where there is much cloud, as at Drumlanrig, there is little dew. Where the temperature is variable, as in "clear bracing" districts, there is at times a great deposit of atmospheric moisture. I am certain that if blinds were provided and could be drawn over the glass during clear cold nights they would do what the clouds do at Drumlanrig—arrest radiation and prevent the surfaces of the Grapes becoming colder than the air surrounding them, and dew and decay would alike be prevented.

The power of Grapes in condensing atmospheric moisture in clear bracing districts is abundantly evident in September when Vines are grown in the open air, for the bunches are clouded with moisture on every clear cold morning. Precisely the same law is in operation in vineries in the winter when circumstances are favourable. It is the gardener's duty to render them unfavourable, and to do this effectually he must be acquainted with the principles of heat-radiation and dew-formation, and must act in accordance with them. That those principles are not familiar to all who have the charge of vineries is apparent from a question that was put to me the other day. "It's all very well," remarked my interlocutor, "you talking about dew getting on the Grapes; but I should like for you to tell me how it gets in the vinery. If glass will keep rain out I should have thought it would keep dew out." I could only reply by asking him how he thought the cold and air got in. The fact is that both the Grapes and glass that covers them radiate heat with great rapidity, more quickly even than metals, and the temperature of their surfaces falls to the dew point sooner than does the surface of a sheet of iron. There is, therefore, no wonder at dew forming on the Grapes in clear bracing districts unless means are adopted for preventing it. Those means are fire heat and ventilation, for blinds to arrest radiation are not yet provided.

Fire heat, I suspect, is occasionally if not frequently applied in vineries at a time when some of it might be dispensed with; and, on the other hand, is withheld when it ought to be employed. What is more common than to find much fire heat applied during dull and rainy weather? yet the glass at that

time is so clear as to prove the absence of condensation, and the berries are so warm that moisture cannot be precipitated on them. A certain amount of fire heat is, of course, necessary in damp weather, and especially if it is cold as well as damp; but in bracing districts liable to sudden and extreme fluctuations of temperature as little fire heat as possible should be employed during mild weather, or injury will inevitably follow when cold days and nights ensue, or rather when the next spell of mild weather follows the cold. The great variation of temperature which the Grapes are subjected to must promote the deposition of moisture on them as certainly as dew forms on the grass during a cold clear morning following a dull mild day in spring or autumn.

But while we find fire heat is freely employed during dull and mild weather, we often observe it is to an undue extent withheld during cold and clear weather. This is a mistake. I have, as have many others, frequently received instructions not to apply fire heat during cold clear weather, because the atmosphere was evidently dry and there was no damp to dispel; yet fire heat was really required, not to dispel damp perhaps, but to prevent the Grapes becoming so cold as to form powerful condensing bodies for the atmospheric moisture during the suddenly and often extremely mild weather succeeding. On several occasions last winter, and on more than one occasion this, striking evidence has been afforded in districts where the weather is alternately clear and dull, cold and warm, of the deposition of moisture on cold surfaces. We have seen and heard of complaints of everything being damp. Not only has the water been said to "come out of walls," but it has made furniture dull and linen clammy. This has always occurred when mild and dull has suddenly succeeded several days of very cold weather; but certainly the water did not come out of the walls, &c., it came out of the atmosphere, and was condensed by the cold surfaces. Exactly the same law operates in vineries when the conditions are favourable. If by non-firing in clear sharp weather the surfaces of Grapes are permitted to become very cold, they will inevitably condense the moisture of the atmosphere when the temperature rises and becomes several degrees warmer than the bunches. When this occurs frequently, and to a great extent, the Grapes cannot be kept sound.

In certain districts and seasons we cannot prevent a deposition of moisture on the bunches, but if we adapt our practice in accordance with the principles of dew-formation we shall very considerably mitigate the decay of our Grapes. —A NORTHERN GARDENER.

IF "A NORTHERN GARDENER'S" premises had been correct no doubt his conclusions regarding the immunity of Grapes from decay here would have been correct also. But his premises regarding the climate are not correct, consequently his solution of the question is not likely to be the true one. He concludes that the climate of this district is remarkable for its equable temperature and absence of dew. But if it be remarkable for anything, it is for its unsteady climate. For its heavy clouds and downpours of rains it certainly is remarkable, but not more so than for its constant and sudden changes from such weather to that of clear starlight skies, and consequently its intervals of rapid radiation resulting in heavy dews and frosts. In this particular feature I have never lived in any climate that approaches the valley of Drumlanrig. Perhaps "A NORTHERN GARDENER" may be surprised when I state that I have seen a fluctuation of 57° in sixteen hours. Particularly about the time that Grapes are at their most critical stage for mould and decay is the locality singularly subject to the rapid alternations I have referred to. The absence of any fear of losing the smallest per-centage of berries has led to a more than usual carelessness in the application of fire heat to guard against the evil. So that neither the one nor the other of the causes named by your correspondent can possibly be credited with the very remarkable absence of decay in Grapes here, as compared to any former experience or observation of mine. Nor does this immunity apply to one but to all varieties of Grapes grown here.

"NORTHERN GARDENER" refers to the question of covering Vine borders to throw off autumn and winter rains. This is a practice that, in the case of Vines not to be started before the middle of February, I have come to regard as an evil. For several years after coming here the Vine borders were covered with wooden shutters resting on supports 8 inches off the surface of the soil. The borders were to my mind in a more unsatisfactory state when so covered than they are now when they are

not covered. Of course, stagnant water about any part of the border is and should be an impossibility when exposed to sometimes 12 inches of rain in one month, a fall which not unfrequently takes place here in the months of November and December. The subsoil is, in the first place, a layer of impervious yellow clay, but when that is removed there is 20 feet or more of open shingle into which a brook would disappear. I have this season made a new border for Peaches, &c., and have removed from 15 to 20 inches of the clay over a surface of 500 feet by 22 feet, and replaced it with brickbats and stones resting on the said bed of shingle.

In changing from one locality to practise in another the very opposite in its geological formation and climate, the practitioner has many of his old notions exploded, and he gets his sympathies very considerably "broadened" regarding the sometimes apparently conflicting directions and discussion which go on in the gardening press.

It may sound rather paradoxical when I say that with a rather heavier and deep loam, and with sometimes within a few tenths of 6 feet of rainfall in the year, vegetation suffers far more from drought at intervals here than in East Lothian with less than half the rainfall. It happens in this wise: Vegetation that makes its growth with a maximum of moisture suffers far more when overtaken with drought than is the case in a drier and steadier climate. Hence I never saw vegetables suffer so much as they do here when overtaken with a period of drought, and to cope with this point in culture a full and complete system of waterworks with great pressure are just now in progress.—D. THOMSON, *Drumlanrig Gardens*.

LATE CHRYSANTHEMUMS.

"A KITCHEN GARDENER" wishes to have Chrysanthemums throughout the month of January, and very reasonably thinks they would be very useful so late in the Chrysanthemum season. Last year I had quantities all through January—indeed, it was into March before the last of them were over. At the present time we have plenty of Chrysanthemums for cutting from, the very latest only showing colour in the bud as yet, so that there is every reason to hope for a good supply during the next four or five weeks. I am not acquainted with any two flowers more useful than the Chrysanthemum and the best varieties of zonal Pelargoniums for supplying cut flowers during the winter season. They are both of the easiest cultivation and last longer when cut than most flowers. I find them indispensable.

In 1876 a reserve lot of Chrysanthemums was planted in the kitchen garden when the main supply was potted into their blooming pots. These planted out were lifted in October and replanted in the front of a late Peach house, the trees being trained against the back wall. Most of the plants in pots were out of bloom by Christmas, while those transplanted from the open ground to the inside front of the Peach house were fine all through January and part of February, and did such good service that this year a large border in the kitchen garden was filled with plants, and late last autumn they were transplanted to every bare portion of wall under glass at all suitable for the purpose, besides a double row in front of the Peach house. Of course, such a method of growing Chrysanthemums will not furnish the fine blooms that growers of this flower try to obtain; but to those who, like myself, require a continual supply of cut flowers during the dreariest portion of the year I am sure they will find the mode of culture referred to of great service.

I have considerably reduced the number of varieties, finding a limited collection as to sorts give more flowers than depending on a great number of varieties. Mrs. G. Rundle, Mr. G. Glenny, Elaine, Fair Maid of Guernsey, St. Justitia, President, Venus, Pyramidale, St. Michael, Julie Lagravère, Mrs. Kaines, and Prince of Wales are a good dozen for cut-flower work. Fleur de Marie (Anemone) is also a good late variety. I grow many more sorts, but I depend on such free and useful varieties as those named for producing a full and long supply of flowers. —R. P. BROTHERSTON, *Tynninghame*.

AMERICAN BLIGHT.

PARAFFIN is a sure cure for American blight if used as received from the stores and applied in winter with a painter's brush. I have trees here that two years ago were smothered with this blight; it hung in strings from the branches. I had them thoroughly painted with paraffin, and now they are per-

fectly clean. Peas before sowing I always soak for eight hours, pouring enough oil to cover them, then drain it off and sprinkle the peas with red lead to dry them. Mice never touch them, and they always vegetate well.—J. GIBSON, *The Gardens, Brentley House*.

ROSES—JUDGING AND CLASSES.

OUR friend "C. P. P.'s" letter will, I feel sure, be read with interest by all Rose exhibitors, as it touches on the vital point for them to know—viz., that their exhibits will be accurately and clearly judged by a given code of rules, which they may read for themselves, study, and work up to. In a previous number of the Journal I endeavoured to give some such practical definite rules for judging Roses by their points and reasons for so doing, and I still see more than ever the urgent need for this being carried out by the grand National Rose Society. Each year our exhibition stands are advancing nearer to perfection, and the time is past when we could almost at a glance detect the best box of blooms. Exhibitors now require judges to go carefully into a numerical calculation from given points. This will entail increased labour. The closer and more perfect the exhibits the greater the labour. Probably there will not be found a more simple and effectual method than that of using small strips of card on which are printed the point numbers. These may be quickly gathered up and recorded by the Secretary's assistant. This plan cannot fail to be accurate and truthful, which is of the greatest importance where a fifty-guinea prize is at stake.

Before the "National" publish their prize list there is another subject which the west of England men would like to see mooted—viz., that the premier class of seventy-two singles should be represented by at least six prizes (however small), to give room and more encouragement to distant exhibitors in this splendid class.—HENRY CURTIS, *Torquay*.

EARLY PEAS.

No one has a garden without making an effort to have early Peas. How success may be wooed and won will always be a matter of interest to many of your readers. I will, therefore, allude to three systems that recently came under my notice in this locality—Clonmel, leaving your readers to infer which, if any, they approve:—1, Sowing in the open ground; 2, In cool frames; and 3, Forcing with heat.

"Carter's Practical Gardener," page 79, recommends sowing-out about the 20th of November, but prefers "sowing in a frame in the beginning of March, hardening-off and planting-out before the end of the month." Here I may note, whether this frame sowing is done in pots or in the frame loam, the young rootlets must necessarily be disturbed in transferring to the open ground. But my principal object in quoting the above is to ask whether it may not well be doubted that sowing in a cool frame in March will give you early Peas.

A gardener of twenty years' experience tells me he has successfully adopted the following plan. Sow in lines on a warm border in November; cover with green furze tops. Put two rows of leafy stakes, one on each side, and joined at the tops, say 18 inches high. Remove those for taller sticks when all danger to the young foliage has passed, and you will have, like him, early Peas in the open ground in May, taking it for granted the soil and manure are suitably rich and properly prepared.

2. With frame culture. I think the following plan, shown me yesterday by Mr. John Crehan, head gardener, Minella House, specially deserving notice. A cool frame with a southern aspect is used. The seeds are carefully deposited in pieces of turf, from which some of the clay has been shook, and these are evenly laid along the bottom on a gentle sunny incline. Over them is strewn some old loam or potting refuse, and more robust or healthier plants one could hardly wish to see, having the great advantage of being gradually hardened-off and of being ready to remove to the seed lines at pleasure without disturbing a rootlet, as the pieces of turf can be lifted easily on the hand without at all interfering with the plants.

3. A third system I saw in this vicinity was in marked contrast. The seed was started in small pots in a lean-to structure, the walls of which were beneath the surface, and in which a warm temperature was regularly maintained. The plants were 3 or 4 inches long, thin and delicate; and I doubt whether, with any prospect of success, you could expose them in a cold damp soil, such as we may necessarily expect during the next

two months, not to mention the chances of a dry east wind, or worse still, a few degrees of frost, or 15°, such as we lately had here.—W. I. M.

IBERIS NANA.

I HAVE read with pleasure what has recently been published on some of the species of this valuable genus of hardy spring-flowering plants. I have a very dwarf-growing Iberis with large round flowers which I esteem very highly. I obtained it several years ago under the name of *I. nana*, and I consider it one of the gems of my rockery. It only grows a few inches high, but its flowers are much finer than some other Iberises of larger growth. It is rather a slow-growing plant, and on

Fig. 12.—*Iberis nana*.

that account is cherished the more, since it is less likely to become common. I know nothing about the origin of this Iberis, but have been told that it is a garden variety. Can you inform me on this point? It is distinct from any others that I have seen, and its large pure white flowers are very beautiful in early spring.—D. D.

[*Iberis nana* is a native of the Piedmontese Alps, and seeds were sent by Dr. Fisher of Gottingen to Mr. Murray of the Glasgow Botanic Garden, who raised plants from them in 1822.—Eds.]

MORELLO CHERRIES AS STANDARDS.

MORELLO CHERRIES are usually planted on north borders and trained to shaded walls. In such positions they succeed well and ripen heavy crops of fruit. It may, I think, be taken for granted that any kind of fruit that will ripen on a north wall, where the sun seldom reaches, will ripen equally well when grown in an open position of the garden, the trees being either trained as espaliers or grown as pyramids and standards. Pyramids of Morello Cherries may occasionally be seen, and attractive and profitable they are; but standards are seldom met with, yet there is nothing to prevent such trees from succeeding.

Morello Cherries will grow and fruit when grown as standards at least as well as will any of the dessert Cherries or as Plums, and yet we find Plums of all sorts grown as standards, and Cherries of the Duke and Heart types, but we rarely find the most certain cropping of all Cherries grown in the same manner.

Those who have a good supply of Morello Cherries know how useful they are for culinary purposes as well as for preserving in brandy for dessert; yet many, it is to be feared, do not possess them, because they have not walls whereon to train

the trees, nor, perhaps, conveniences for growing them as pyramids. Let such try them as standards, and in due time they will have a supply of fruit which the birds will leave until the last, and which the cook will welcome for tarts and the housekeeper for preserving.

Morellos when grown as standards do not make large round-headed timber trees, but form medium-sized trees of a semi-weeping character. When such trees are blooming they are extremely ornamental. Last year I heard a tree described as resembling a "fountain of snow," and certainly no tree in the garden or shrubbery was at the time more beautiful; and in the autumn, when laden with its richly coloured fruit, it was equally attractive. The tree referred to always bears heavily, and both in 1876 and 1877 it was the only tree in the garden that yielded a full crop. Better evidence than that is, I think, not required as to the suitability of this Cherry for that simple mode of culture.

Having observed this profitable old tree, I a few years ago planted two young Morellos as standards, and left them to grow in their own way. The result is highly satisfactory, for they bear prodigiously, and the fruit is fine and ripens well. When thus grown the trees bear little or no fruit in the interior of the heads, but only on the outer branches, which assume a pendant character, and the whole outer surface of the tree becomes a close mass of young wood, from which the fruit can be gathered by handfuls. Little or no pruning is required, but occasionally a slight thinning-out of the branches is necessary, attention in this respect being almost identical with that given to the Black Currant.

Since attention has recently been directed to the subject of growing fruit trees in shrubberies and pleasure grounds, it may be opportune to notice the claims of the Morello Cherry both as an object of ornament and utility. Few other trees are more attractive when in bloom, and no fruit trees afford less temptations to boys and birds when the fruit is ripening. They are thus particularly suitable for growing amongst shrubs. This Cherry, moreover, grows so freely that a check given by the shrubs appropriating the lion's share of the virtues of the soil would be an advantage rather than otherwise, in arresting the exuberant growth of the Cherry trees and promoting their fruitfulness.

Unless there is a north wall in a garden we rarely find Morello Cherries. Latterly, however, they have been planted as pyramids, and have proved to be amenable to pinching and pruning; but the natural character of this Cherry is to bear on the young wood the same as the Black Currant, and the simplest plan of obtaining fruit is to permit the trees to grow in a natural manner and form small semi-weeping standards. Wherever the fruit will ripen on north shaded walls it will ripen in the open where the trees are grown in a free natural manner, and such trees are both pleasing in appearance and profitable.—J. S. P.

SHADING CAMELLIAS AND OTHER SHRUBS.

SOME notes on this subject have appeared in your Journal from the able and practical pen of Mr. Thomson, Drumlanrig. He cites an example of finely flowered Camellias at Wrotham Park many years ago without the use of any shading whatever. I do not at all doubt this; still I am of opinion that shading Camellias at the time they are making their wood when the foliage is tender is generally an advantage. Though it is an advantage, still I have no doubt that the amount of light and sun that a Camellia will stand without being browned or scorched is about the mark to be aimed at—that is, provided the plants are not so affected, the more sun they have the better.

In the conservatory here, in the upper part of it, where ventilation is not well provided, unless we put some white-wash on the glass to check the strong rays of the sun while the wood is young, the foliage is liable to be injured. The plants are large and fine, being nearly 20 feet high, and last season, as they do every year, bore a profusion of flowers. In our Camellia house, where we grow the plants in pots, we find it best also to shade partially.

Mr. Thomson mentions amongst the fine-flowered Camellias *Chandlerii* elegans. Well, I may just note a plant of *Chandlerii* here. It is about 6 feet high in a pot, not quite 2 feet through. All summer we had it in the plant stove, subject to shade or no shade according to the weather. It was literally covered with buds; I reduced them to about two to a shoot. Just now they are of the most beautiful character, opening

half red and half white, and perhaps the only fault is the disproportionately large green leaves of the plant, which harmonise rather coarsely with the beautiful buds. Just now we have Jubilee with very fine flowers, not so much given to the double flower (two flowers in one) as it is sometimes. *La Reine* is one of the most beautiful Camellias. In regard to it I may observe that a large plant about 10 feet high, which stood in the corner of the conservatory, and receiving, as it did, rather more than an average share of sun, the foliage was brown instead of green, and I believe had it been more shaded this would not have been the case. For my part I much prefer a moderate number of flowers and having good foliage to a superabundance of flowers and inferior foliage. This season I had the first white Camellia on the 12th of September, and have had them more or less in profusion since November. We shall have them so in the conservatory until April, when their place is gradually taken by specimen Azaleas, the larger plants being 6 feet by 6 feet. These make a very effectual succession. The light and bright masses of Azaleas under the green foliage of the permanent Camellias is very fine indeed. The white and red varieties of the former are magnificent.—R. M. A.

THE POTATO DISEASE.

THE letters on this subject, including the last, signed "AMATEUR, Cirencester," have already been so ably responded to by "PERONOSPORA" that very little remains to be said. "AMATEUR," however, in his last letter introduces my name, and says, "Still nobody knows how long they [*i.e.*, the resting spores of the Potato fungus] live or where they pass the winter." Now, the whole aim of my late experiments was to solve this difficult problem, and I think it was done somewhat effectually by my keeping the diseased Potato material under daily observation for more than a year. I need hardly remind your readers that when a year had nearly passed away, and just at a time when various enemies and scoffers big and little were busily employed firing shots at me (all misses) my so long quiescent, but not dead, resting spores suddenly started into renewed life and reproduced the fungus of the Potato disease. I at once divided my material into portions and distributed it amongst four or five of the best microscopical observers in this country, and these men one and all confirmed the truth of my observation—that the resting spores germinate after a year's hybernation in decayed vegetable material, water, or earth. Mr. Smee's case is very incompletely stated by "AMATEUR," and the statement as to Professor Tyndall's views is erroneous.—W. G. SMITH.

THE APPLE TREE IN THE PLEASURE GROUND.

MR. COLE's remarks on page 6 apply to a subject of considerable importance, and one which, in a very direct manner, combines beauty with utility. What can be more beautiful than fruit trees in full blossom? and what more useful than the autumn harvest of fruit following? I have often observed the cheerful appearance of Almond trees in pleasure grounds during the blossoming period, but Apples when in full blossom are still more beautiful, and valuable fruit follows in due course; yet in pleasure grounds and villa gardens there is not one Apple tree planted where are a hundred Almonds. Occasionally we see an Apple tree amongst evergreens, and when so it is sure to be admired. Why, then, are not more trees planted? Probably the chief deterring cause is the fear of the fruit attracting the attention of trespassers—a fear I cannot help thinking that is unduly magnified.

A few years ago I was consulted by a retired tradesman as to the best mode of planting the ground at the front of his house so that it might look ornamental from the windows and also from the highway, which was and is a busy one. A pleasure ground of shrubs was desired by the owner, but he did not know what sorts were the most suitable. Instead of having shrubs entirely I advised him to plant also several fruit trees. He adopted the suggestion, and eventually more fruit trees—pyramids of Pears, Apples, and Plums, but chiefly Apples—were planted than shrubs. The result has proved highly satisfactory. The garden is admired by passers-by, not in the spring only when the trees are blossoming, but equally so in the autumn when the fruit is ripening. It is not the evergreens, handsome though some of them undoubtedly are, which the public admire so much as the fruit trees, and their owner admires them too, for it is a poor year if he does not

sell £20 worth of fruit out of his miniature pleasure ground beyond what he requires for home use. It is certain that the surplus fruit more than defrays the cost of keeping the garden in order; and although it is only divided by a low fence from a populous highway, and the entrance-gate is never locked, yet not 5s. worth of fruit has been stolen or damage sustained since the trees were planted.

There are hundreds of villa gardens which might be rendered additionally attractive by interspersing a few fruit trees amongst the shrubs, and the produce of the trees could not fail being acceptable. Mr. Cole's suggestion is worthy of consideration by owners of gardens large or small, for fruit-tree blossom is always beautiful in its season, and wholesome fruit is ever welcome.—A SQUIRE'S GARDENER.

ROSE SHOWING.

It was with much amusement and not a little surprise that I read the short letter signed "A LOVER OF ROSE SHOWS" on page 47. "Set a sprat to catch a whale" was the remark I made upon reading his question. "If I procure three plants each of the first fifteen sorts in the election lists shall I be safe for showing twelve single trusses at two or three of the metropolitan shows next summer?" Indubitably No is my reply, and I think that anyone who has any knowledge of Rose-showing will endorse this opinion.

In the first place, the class for twelve varieties is one of, if not the most difficult of all, and for this reason—so many amateurs are able to show twelve who cannot show in any other class; and to show twelve well you ought to have the pick of hundreds if not thousands of plants. Again, fifteen varieties is so small a number of sorts, that when you bear in mind the different times at which certain of the best varieties bloom, the odds are that not more than six or nine would be in bloom at any given time. Further, a good Rose plant treated successfully and properly disbudded should not bear more than four blooms. Mine rarely are allowed to give more than two; the whole strength of the plant should be centred in these two buds, therefore it is a foregone conclusion that three plants could not be expected to give a show bloom on three distinct occasions. Everything also would depend upon the dates of the great metropolitan shows corresponding with the early or late soil that your correspondent possesses, also whether he lives in a southern or northern part of this tight little island; so that I should recommend him to give up all idea of showing twelve unless he can buy a few more.

Your correspondent also seems to have entirely misunderstood my remarks. The advice given on two occasions was not contradictory, as he supposes, but altogether the reverse. In the one case I say an intending exhibitor will require twenty plants of each sort, in the other I say a man who wishes to show twenty-four trebles, a most difficult number to show, requires at least fifty good plants of thirty sorts. Your ingenious correspondent, probably to show his knowledge of arithmetic, has divided the fifty by twenty-four instead of multiplying. Surely the meaning is obvious and as plain as the Queen's English will allow. Fifty plants of thirty sorts; it surely would be redundancy to say fifty plants of thirty sorts each, or thirty sorts and fifty of each sort. Such is, of course, my meaning. I would advise your correspondent to buy twenty plants of twenty-four varieties, all good growing sorts, and set to work without delay; then, perhaps, he may hope to compete with Mr. Baker, who certainly has three hundred of each sort, or Mr. Jowitt, who probably has five hundred of each.

But not content with trying to prove that I contradict myself in two letters which appeared in "our Journal," your correspondent accuses me and Mr. Peach, and all others who wire Roses, of cheating. Terrible charge! Cheating to wire a Rose! Well, we live in an age of progress, and perhaps Rose-growing and Rose-showing will in due time be so altered that we shall go back to the old plan of exhibiting our blooms in medicine bottles with a label on some—"Very weak in the back, requires support."

But is your correspondent such a tyro in Rose-showing that he does not know that Tea Roses and some slender-stemmed Hybrid Perpetuals will not do as he does—stand up and present a bold front before an astonished public? They have not the strength of character he has. They are modest and must be assisted before they will turn their lovely faces to the judges; in fact they must have wires in their stays, or like some fair damsels they collapse. Apart also from this, there

is no rule in Rose-showing that affects wiring, and what is open to me and others is open to your correspondent. Perhaps he will on reflection see the modesty that he practises with regard to the limits of his Rose orders is not quite in consonance with the modesty (?) that he as a beginner evinces in accusing me, and every Rose-grower who exhibits, of cheating. There is no art in wiring, or, as my friend Mr. Peach puts it, securing heads of Tea Roses to bits of stick. So instead of inveighing against an established custom, your correspondent had surely better employ his leisure time in practising wiring.

I cordially concur with the advice given by Mr. Hubert Bensted, and I do not think that to an understanding mind there is much difference between his advice and my own. It stands to reason that you ought to possess a great many more plants of a weak grower than of a strong vigorous sort. I remember Mr. Jowitt showing a marvellous bloom of Marquise de Mortemart at Torquay last summer. "I had to cut the whole of the plant away to get that bloom, and have had to place a mark to show where it is," was his remark to me. It is evident, then, that of such a Rose as this you should either possess a hundred plants or none at all. I freely own I cannot grow the sort, and so have given it up; and I strongly recommend your correspondent not to think of growing such varieties unless he can largely extend his Rose-growing.

The season so far has been so mild that here in Dorset my old plants have not shed all their leaves. A Magnolia flower was brought in yesterday, and the Gloire de Dijon has never been out of flower all the winter. We shall suffer for this hereafter, and I shudder to think of the mischief the frosts of next May will cause.—WYLD SAVAGE.

I FEAR that "A LOVER OF ROSE SHOWS" will have to dip more deeply into his "but slender purse" than he at present anticipates if he is desirous of winning his spurs at any good metropolitan Rose show. It is evident that he has quite misunderstood "WYLD SAVAGE's" remark that "a man who wishes to show twenty-four trebles well ought to have about fifty good plants of thirty sorts," since he explains, for the benefit of your readers, that this means about one plant and a half of each variety. Although I have no wish to dispute the accuracy of his mathematical logic, he must allow me to point out that his deductions are entirely wrong. It is quite evident that "WYLD SAVAGE" means that an exhibitor of twenty-four trebles should have fifty plants of each of thirty sorts; and I fear your correspondent will be much disappointed with his purchases if he has cherished the fond hope that he will be able to cut upon any casual day during the Rose-showing time an average of rather more than three show blooms to each two plants. Further, the information he seeks to obtain through the "Rose Journal" as to whether he will be safe by procuring three plants of each of the first fifteen sorts in the Rose-election list for showing twelve singles at the metropolitan shows will be anything but encouraging to such small but ambitious growers as himself. From the number he mentions he would not have the slightest chance of a prize in even a six-variety class at a good metropolitan show such as the National, Crystal Palace, Aquarium, &c.; in fact, to show a really good "twelve" such as the twelve which took the first prize at St. James's Hall last year, an exhibitor should have grown twelve to fifteen hundred established plants, and these not purchased but budded upon Briars of his own from the plants he buys at a nursery as a commencement of his collection.

As regards your correspondent's remarks about wiring Roses, he has certainly much to learn on the subject of showing if he thinks that a box of blooms well "set up" so as to keep a uniform height and display their charms fully to our admiring gaze ought to be disqualified in favour of one with all the weaker sorts (many of the Teas for instance) hiding the delicate beauty of their centres from all save the unappreciative moss below them.—A. G. S., *Irnham*.

THE PRESENT SEASON.

I LIVE within four miles of the Liverpool Exchange and on high ground, and yet on the 10th of December I had fully expanded blooms of Rhododendron Nobleum in the open without any shelter whatever; shrubs exposed to the N.W., N., N.E., and E. winds. I lifted some and placed them in the conservatory, where they are now one mass of blossom. Those left in the borders opened their buds beautifully, and were looking brilliant until the 9th inst., when we had a sharp frost

after a very heavy dew, covering everything with rime, and this completely destroyed the expanded blooms. I think December 10th is particularly early for the *Nobleanum* to be in bloom, but yet, notwithstanding the mild weather, no other shrubs appear to be forward, neither do the Apple bloom buds show any sign of being before time.—J. W.

JUDGING ROSES.

IN judging Roses I think we must dismiss from our minds the elaborate proposals which have been made as to taking the number of points in each flower—form, colour, freshness, &c.; it is simply impossible. Imagine how this would be in judging thirty or forty stands of twenty-fours, or half a dozen stands of seventy-twos, each flower to be put down on a piece of paper and its merits put opposite to it. Why, the lengthening shadows of evening would have fallen upon the earth before the judges' work could be done. Again, it is impossible for any judge, however well qualified, to give entire satisfaction, although I am bound to say it is not generally the exhibitors who question the decisions the most loudly. I do not in the least desire to underrate the difficulties of judging, and the difficulty is sometimes increased when there are three judges, from the fact that they have different ideas as to the perfection of a stand of flowers. It is for this reason that I for one should like to see some broad general rules laid down by the National Rose Society. Take, for instance, the number of Tea Roses in a stand. Some judges immediately seize on this point and say, "Ah! there are six Tea Roses in that stand; that is a great point in its favour." Now, I for one cannot see this. I admit the great beauty of Tea Roses. Some of them, and only some, set off a stand; but I do not think they ought to have anything in their favour because they are Teas. It is as easy to grow a Tea Rose in Devonshire or Cornwall as it is to grow a Hybrid Perpetual, and in judging a stand you cannot of course tell the place from whence it comes or the difficulties the exhibitor may have laboured under. Then there is another point about which judges differ, the symmetry of a stand—*i.e.*, the general evenness of the flowers. It is for this cause, quite as much as for their innate coarseness, that I dislike such Roses as Paul Neyron or Antoine Mouton. They at once disarrange by their great size the even beauty of the stand. It seems very much like putting three horses of 15½ hands into a drag, and the fourth about 16½ hands. You at once say that is not a nice turn-out. Someone has spoken of the freshness of the blooms as a point in their favour; doubtless, but then at what disadvantage are those growers who have to bring their flowers on perhaps a hot July night two hundred miles, and to shift them about from rail to cab, &c., to those who can drive in their own vehicles some fifteen or twenty miles in the cool of the early morning. Some years ago I was bold enough to propose that moss should be done away with, and I see "C. P. P." agrees with me. Certainly some exhibitors by the facilities they possess of access to good moss have a great advantage; but it would make a material difference in the carriage of cut blooms, for there is no doubt that the great amount of moisture the moss contains very materially helps to keep them fresh on a long journey.

In some points I disagree with my good friend. I do not think that because a stand contains some good blooms of a miffy grower that therefore it ought to have some points in its favour. There are some localities where certain kinds seem to thrive better than others, but if an exhibitor lives there it is not much in his favour that he can grow them; moreover, it does not help the general public. One sees a good bloom of *Madame Furtado* and thinks that he should like to add it to his collection; he does so, only to experience vanity and vexation of spirit. To me it seems the Roses should be judged according to what they are on the morning of exhibition, their vigour or otherwise having no place in the judge's mind. A fine bloom of *Jules Margottin* is quite as deserving of consideration as a good bloom of *Madame Furtado*.

I must break a lance with "C. P. P." in defence of my dear old friend Mr. Radclyffe. He is not an exhibitor but a thorough good rosarian, pursuing his love under great difficulties, and when he gives his lists of Roses I do not think he has the exhibitor so much in view as the general lover of Roses. He would not have all but exhibition Roses excluded from his garden, and if he has recommended Roses which others condemn, I can only repeat what I have already stated in this Journal—that in his garden I have seen glorious blooms of kinds which many of us have cast out. For the general

grower (not exhibitor) he insists on vigour as absolutely necessary to qualify a Rose for admission into a garden, and in this respect he is a safe guide. May he long be spared to encourage the growth of his favourite—nay, his only flower.—D., Deal.

PROTECTION FOR FRUIT TREES.

ONE of the greatest points in a gardener's favour is his ability to adapt himself to circumstances. He who can and readily does so ought, and pretty generally does, command success in matters where others perhaps have failed. However, in some cases, and especially with regard to protecting wall trees when in bloom (unless employers are fully alive to the importance of the work and are willing to provide proper materials for so doing), the gardener, if obliged to use such materials as the place only affords, feels that success is very uncertain indeed. Too often, I am afraid, gardeners are blamed for a short crop of Peaches, &c., by unthinking employers, who perhaps some time or other have refused to buy the proper appliances for protecting. If the gardener does nothing he will, perhaps, have to listen to the following indigestible remark—"How could you expect a crop of fruit when you know nothing was done to protect the bloom?" Consequently something must be done if known to be a miserable makeshift. In many places poles are to be had (those that unfortunately cannot obtain them are still worse off), and are laid in a slanting direction from the ground and firmly fixed to the top of the wall; to these are attached various kinds of protecting material. I have seen the following used—the undergrowth of the Spruce and other Firs, fruit nets doubled and trebled, Archangel mats, home-made hay mats or nets, straw mats (the two last made by the labourers during bad weather), strips of old carpet, canvas, &c. No doubt in some instances they are more or less effective, but it not unfrequently happens that parts of the protected trees and others unavoidably left to take their chance carry as much fruit—at all events as much as is wanted—as those over which so much labour has been expended. Ordinary spring frosts may be broken by very slight protection, but if heavy winds are prevalent those very appliances often prove very destructive in themselves. I have seen fruit nets covered with ice dashing against the trees, doing much damage to the blossom, expanded or not. Heavier materials, unless very securely fastened, are still worse, and also tend to forward and weaken the blossom. What is really wanted is something light, yet of a nature to check the radiation of heat, and is also a non-conductor of cold; these essentials are to be found in the frigi domo.

This material is made principally of hair and wool, a good amount of the latter being used. Both possess the above-mentioned essentials, wool remarkably so. This is exemplified in the use of large quantities of woollen fabrics for winter clothing, &c., simply because being non-conductive they prevent a too rapid loss of the heat of the body by radiation. This peculiarity of wool has also been demonstrated by experiment.

The frigi domo, if properly hung, not only excludes what I believe to be most destructive to the delicate blooms of fruit trees—*viz.*, cold winds accompanied by sleet, snow, &c., but also wards off several degrees of frost, and is in effect next in point of utility to a glass-covered wall. Many methods of hanging the frigi domo are in use, but the following is the best I have seen. For example, I will take a Peach wall 13 feet in height and 50 feet in length. It is occupied by four trees, allowing 12 feet 6 inches in width to each. Four boards, each 12 feet 6 inches long and 9 inches wide, loosely fastened with strong staples at the ends, are attached to iron supports driven under the wall coping. Thirteen poles are used; one at each extreme end, one to each junction of the inner ends, and the others placed at equal distances in the intervening spaces. These are let into the ground for firmness about 18 inches from the wall, and nailed to the boards behind the rods. The frigi domo—in 12-feet-6-inch lengths, previously bound, brass rings 1 foot apart are attached to the inner side at the top; and tape strings for tying down at the bottom and inner ends to the poles, and the extreme ends to nails or staples in the wall—is then run on to the rods, which, if fastened as before advised, will slide for that purpose. Other widths of the frigi domo and other materials can be used in the same way, modifying the plan to suit the wall.

The advantages, not forgetting the respectable appearance of the above method, are obvious, one of which is the ease

with which they can be drawn out and the small amount of space occupied when drawn back and tied to the poles. I have found it especially useful during the prevalence of bitter, drying, easterly winds, than which I think nothing is more destructive to the fruit crop. Such winds check the growth, and consequently subject the trees to attacks of various enemies. During such weather, and again if very bright and mild weather is bringing the bloom on too early, the blinds should be kept drawn out, and in the latter case run back at night neatly folded and tied to the poles. The blinds can also be employed for hardening bedding plants, retarding the ripening of a crop, protecting when ripe from insects, &c. They do not absolutely insure a heavy crop, but failures are rare with the exception of the Apricot. In Leicester and Derby shires the Apricot seems quite at home, and is as frequently to be seen on the cottagers' dwellings as Plums and Grapes are in the south. Few make any attempt at protection, but usually obtain as good a crop as those receiving every attention in the gardens of their richer neighbours.—W. IGGULDEN, *Orsett Hall*.

NOTES AND GLEANINGS.

We understand that a meeting of the Executive Committee of the NATIONAL ROSE SOCIETY will be held at the Horticultural Club on Tuesday next the 29th inst., and that one of its chief duties will be the drawing-up of the schedules for the metropolitan and provincial shows; and we are authorised to say that if any member of the Society has again suggestions to make they will be carefully considered by the Committee. Any communications on the subject may be addressed either to the Rev. H. H. Dombrain, Westwell Vicarage, Ashford, Kent, or to Edward Mawley, Esq., Lucknow House, Addiscombe, Croydon.

THE annual General Meeting of the ROYAL HORTICULTURAL SOCIETY is announced to be held on February 12th, when the usual ballot for seats at the Council-board will take place. The Council recommend the removal of Mr. F. Campion, Mr. W. B. Kellock, F.L.S., and Mr. T. M. Shuttleworth, and the election in their place of Mr. C. J. Freake, Cromwell House, S.W.; Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking; and Mr. J. T. Dillwyn Llewellyn, F.R.S., Penllengare, Swansea.

A CORRESPONDENT suggests that if the NATIONAL ROSE SOCIETY is to offer prizes for amateurs living within the postal district of London it would embrace growers around the Crystal Palace, where the Show is to be held, and bring out a great competition, which could not otherwise be if all the classes were made open to all England.

THE fourth INTERNATIONAL POTATO EXHIBITION will be held at the Crystal Palace, in connection with the great autumn exhibition of fruit and flowers, on September 24th and 25th.

THE following are amongst the arrangements of the ROYAL BOTANIC SOCIETY for the present year:—Spring exhibitions, March 27th and April 24th; summer exhibitions, May 22nd, June 12th, and July 10th; evening fête, June 26th. A special exhibition of Rhododendrons, &c., by Anthony Waterer will commence on June 1st, and Messrs. James Carter & Co. will provide an exhibition of annuals during June and July.

THE most attractive of the flowering plants in Mr. Seely's beautiful conservatory at Furzedown Park are several examples of SPIRÆA THUNBERGII. This low-growing Japanese shrub is found to force with the greatest certainty, the flowers having expanded in a fortnight after the plants were placed in heat. The shrubs are profusely covered with small white flowers, which produce a most chaste effect. The sprays are valuable for cutting for indoor decoration, and are admirably adapted for forming wreaths. In all probability this shrub will prove as valuable as *Deutzia gracilis* for early forcing. It is equally as floriferous as the *Deutzia* but much earlier, which is an important advantage. It is deciduous, and requires the same treatment as the *Deutzia*. The leaves of *Spiræa Thunbergii* are very small, linear-lanceolate, and the flowers are produced in fascicles. So valuable is this plant for forcing that Mr. Laing has prepared a considerable number of it; and those who desire a supply of chaste white flowers in the depth of winter cannot err by following his example.

AS easily cultivated and effective decorative plants during the winter months TYDEAS we think demand more general attention. We refer to them now for the purpose of

noticing a variety named Madame Heine, which we have lately seen flowering in the collections of Messrs. Veitch and Bull at Chelsea. The plant is of dwarf habit, and the flowers are attractive by their rich yet chaste markings. This, like many other varieties, flowers naturally during the winter months, and affords a pleasing change from the usual flowers of the period.

THERE was a very large attendance of the members of the HORTICULTURAL CLUB and their friends on the evening of the 15th inst., when about fifty sat down to dinner to celebrate the occasion of the Club taking up their new quarters in Arundel Street. We trust this will be the beginning of a long course of prosperity to this excellent Institution.

So popular have small INDIARUBBER PLANTS become for room and corridor decoration in London that the demand for them can scarcely be met. They are propagated by thousands, and are sold readily in 48-sized pots. A dwarfier form of the Indiarubber Plant, *Ficus rubiginoides*, is worthy of notice for occupying positions where the more stately *F. elastica* is unsuitable. It is of dwarf branching habit, and is perfectly distinct from its upright-growing congener, which is now so extensively cultivated.

As cut flowers for bouquets and at almost all periods of the year few are more esteemed than those of JASMINUM GRANDIFLORUM. The finest plant that we have yet seen of this valuable Jasmine is in Mr. Wills's nursery at Anerley, and the way it is grown by Mr. Bause is at once simple and satisfactory. It is planted out in a cool stove, and is trained to wires stretched 6 or 8 inches from the glass. The entire roof of a large house is thus covered with the Jasmine, and it is rare indeed that sprays of pure white sweet-scented flowers cannot be cut. The growths are rather thinly trained and do not afford a dense shade, but rather a slight and agreeable one to the plants beneath. Wherever choice bouquet flowers are in request and roof space is afforded it cannot be better occupied than with this free and fine Jasmine. *Stephanotis* is grown in the same way at Anerley, one plant covering many hundreds of square feet of roof, and yields thousands of trusses of flowers. The plant is not more remarkable for its great size than for its excellent health and cleanliness. Mr. Bause's antidote for mealy bug is pure water.

AT the Auckland Institute, New Zealand, on the 22nd of October last, Mr. S. Percy Smith read a note on "THE BRANCHED NIKAW PALM TREE," which in its manner of growth, he said, presented features of abnormal character. It was discovered by one of the survey parties growing in the forests at the base of the Tangihua Mountains, Wanganui. Unlike the ordinary Nikaw Palm, the one under review was stated to possess eleven separate and distinct branches growing from one parent stem, and most of which branches separate from the main trunk at about 5 feet from the ground, and after rising some 10 feet higher some of them dividing again into other branches. The tree itself was about 9 inches in diameter at the ground and about 6 inches just before it divides, the branches being from 3 to 4 inches in diameter. The total height was about 30 feet. The tree was said to present a most beautiful appearance in the forest in which it is situated.

THE *Nelson Daily Times* of New Zealand states that "A GIGANTIC BLACK BIRCH tree was felled the other day by a surveyor's party at Staley Creek, near Ahaura. It is stated to have measured 57 feet in circumference at the butt."

It is surprising what a great improvement may be effected in LAWNS by affording them a top-dressing of rich soil at this period of the year. Where the soil of a garden is naturally fertile lawns continue in good condition for many years without any assistance beyond that afforded by the mowing machine, garden roller, and worms (for worms if at times obnoxious are certainly beneficial to lawns); but where turf has been laid or grass seed sown on poor or shallow soil manurial assistance is as necessary to sustain the grass in good condition as it is to any other crop on similar soil. Mr. Baring's garden at Coombe Cottage affords a striking instance of lawn-renovation. The lawn there has long been unsatisfactory, the grass being of that brown wiry character suggestive of sterile soil. Mr. Baker is, however, steadily effecting a real improvement. Each year a certain portion is heavily top-dressed with a compost of which cow dung forms the chief constituent. The effect is most satisfactory, for wherever the dressing has been given white Clover has appeared as "thick as Cress," although no seed was sown; and the surface of the lawn has been changed

from a poverty-stricken brown hue to a healthy refreshing green.

— By far the finest variety of the species of Fern to which it belongs is *PTERIS SERRULATA CRISTATA MAJOR*. Crested varieties of this Fern are common enough, but they are more or less stunted in growth—*cristata* minors. The variety above referred to merits its name, for it is far more robust than the species from which it originated. Some grand plants of this fine Fern are in the stove at Chiswick, where it is said to have originated. They are about 3 feet high and through, and are additionally attractive by the distinct tints of green, the smooth portions of the fronds being very dark, the crested tasselled terminal portions very light. This Fern combines stateliness with elegance in a remarkable degree, and cannot fail being valuable both for purposes of exhibition and home decoration. Like *Adiantum farleyense* it will maintain its value for a considerable time, and for the same reason—that it must be increased by division, all attempts at reproducing it from spores having been hitherto futile. The spores germinate freely enough, but they produce anything rather than *cristata* majors.

— We have received the *Bulletin de la Fédération des Sociétés d'Horticulture de Belgique* for 1876. It contains full reports of all the meetings and the exhibitions of the Federation, and a condensed report of the transactions of all the horticultural societies in Belgium which constitute the Federation.

— COL. TREVOR CLARKE'S new *BEGONIA MOONLIGHT* has more than once been alluded to approvingly in these columns, and not one word too much has been published in its favour. It is not only quite distinct from all other Begonias, but it is undoubtedly one of the most valuable of all for winter decoration. We admired it this week in a cool house at Chiswick, where it is flowering profusely in the company of *Primulas* and *Geraniums*. The peculiar whitish flowers, which are in great profusion, rise clear above the fine dark foliage of the plant, and the effect produced is excellent. The hardy nature, free-flowering character, and fine contrasting effect of the flowers and foliage of this *Begonia* will ensure its wide distribution and extensive cultivation.

— We have not the pleasure of announcing the production of a *SCARLET CHINESE PRIMROSE* (*Primula sinensis coccinea*), but we have strong hopes that the time is not far distant when that important acquisition will be recorded amongst our winter-flowering plants. The nearest approach to a scarlet *Primula* that we have yet seen is now flowering in the Royal Horticultural Society's Gardens at Chiswick. Plants raised from seed supplied by the celebrated firm of Vilmorin and Co., Paris, are producing flowers of unusual richness of colour, and amongst them is one very nearly scarlet. The flowers are small and have smooth loose petals, resembling in form the *Primulas* of a quarter of a century ago; but the colour is decidedly new, and is a clear advance on any so-called scarlet *Primulas* that have hitherto come under our notice. Although the flowers are small and lack the round overlapping fringed petals of the modern strain of *Primulas* now so deservedly popular, they are freely produced and carried above the foliage, which render the plants highly attractive. As soon, however, as the true scarlet colour is attained it will not be difficult to obtain larger and finer flowers. We welcome the new colour gladly, and can trust Messrs. Vilmorin & Co. and Mr. Barron to make the best of their opportunity of raising a true scarlet *Primula*.

LILY OF THE VALLEY.

MR. W. TAYLOR has stated on page 46 that he has "never seen home-grown crowns of Lily of the Valley flower before Christmas so well as imported crowns do." Now, from experience I have found them to do equally well, having grown some of each, and could not perceive any difference in either earliness or quality. The way the home-grown crowns are prepared is to select the smallest crowns and plant them 4 inches apart in a well-exposed position, which is an important point for the crowns to be well ripened. It takes three years to bring them into the condition for blooming well; some are ready for blooming sooner, but if crowns are planted every year it is not requisite to force them, as they do not like being disturbed. They like a firm soil. When grown thus I have found them quite equal to imported crowns. When the crowns are ready for potting sixteen are placed at

equal distances apart in 48-pots, and potted very firmly with the crowns above the soil, and plunged in cocoa-nut fibre till wanted for forcing. Crowns placed at equal distances apart are far preferable to clumps, as you have the blooms equally over the pot. I do not think further details as regards after-treatment is necessary, as an article was written at page 397, November 4th, 1875.—A. Y.

ZINC LABELS FOR ROSES.

IN opening this discussion my object was to obtain the experience of Rose-growers, and if possible obtain for our Rose trees a label worthy of the flower. I maintain that zinc labels are unworthy, and when fastened with copper wire unsuitable for dwarf Roses.

I feel certain that the cause of shoots dying is not abrasion, or caused in the manner described by "AMATEUR" on page 29; but as I have only used these labels when attached with copper wire, I am unable to state what would have been the result if other wire had been employed. I am inclined to think that to fasten labels of any kind upon shoots is a mistake, but should like to have the opinion of some of our large growers.

The label which if fastened loose causes abrasion, and if fastened tight arrests the flow of sap, does not commend itself to—J. BROWN.

NOTES FROM CORNISH GARDENS.

PENCARROW, THE SEAT OF LADY MOLESWORTH.

FROM the days of L. Quintus Cincinnatus to the present time great and good men, whose lives and actions have left their mark upon the world's history for all time, have shown a fondness for rural pursuits, and especially for gardening, retiring from the cares of state, from the command of armies, from the control of vast mercantile undertakings, to some quiet secluded spot, either to recruit their energies or to end their days; entering upon gardening matters first of all, perchance, with a sense of pleasant relaxation and quiet enjoyment, which soon grows and acquires intensity from that desire to excel, that impatience of mediocrity, that is inseparable from such great minds.

The gardens at Pencarrow afford a striking example of this, for although they have probably been in existence for some hundreds of years, yet under the hands of the late Sir William Molesworth, once Colonial Secretary, they were so much improved and beautified, and have subsequently been so well tended and skilfully managed, that they now stand in the foremost rank of our best gardens. But the master mind that planned with a prescience of development that betokens sound judgment in combination with good taste has passed away, and the thought gave an involuntary tinge of melancholy to the pleasure which I experienced in the inspection of a work that is quite worthy of the designation of great, in company with one who had been an intimate friend of its designer, had discussed much of it with him while it was in progress, and who now told me of Sir William's knowledge and love of trees and art as we strolled among scenes that afforded conclusive proof of it.

Bodmin lies in a hollow among the hills in the centre of Cornwall, and Pencarrow is three miles and a half northwards from that quiet old town. The drive thence to Pencarrow was a pleasant one, over hill and dale, long steep hillsides sweeping downwards to the banks of a salmon river, and stretching far away for miles clothed with a dense growth of Oak coppice that in the distance sorely puzzled me, looking as it did like turf, so densely packed were the tree tops. Other hills and valleys open out in quick and pleasing succession till we reach the woods of Pencarrow. From the principal entrance the drive passes through a Roman camp in an excellent state of preservation, its circular outlines clearly defined by the high banks lying very much as they were thrown up by that old-world sturdy race of warriors. Numerous stunted old Oaks growing upon the banks have a happy effect, being thoroughly in keeping with the scene, which would delight the heart of such a character as Scott has given us in his "Antiquary." Beyond the camp the park opens out, and the drive leads down to the house in almost a straight line for considerable part of the way. It is a long drive, and has broad margins of turf fenced off from the park. The margins are embellished with a collection of Conifers forming a pinetum so extensive, so rich in rare species, and so flourishing withal, that one could very well have spent a day among them with equal profit

and pleasure, but my visit was so short and hurried that a passing glance was about all I could indulge in. Among the most conspicuous trees was an *Abies Douglasii* about 70 feet high, and fine examples of *A. Menziesii* and *A. Morinda* both 60 feet high. *Morinda* is also known as *A. Smithiana* and *A. Khutrow*, the weeping Fir of the Himalayas, where it abounds, growing to a height of 120 feet straight as an arrow, and is sometimes upwards of 20 feet in circumference at the base, as is distinctly stated in one of the latest and ablest works on Himalayan vegetation. I met with good specimens of this fine Conifer several times in Cornwall, but it is by no means so common elsewhere, and yet it is quite hardy, answering perfectly well in Scotland; and there can be no question that its dense pensile growth and general effect is so striking and ornamental as to render it worthy of a place in every garden. *Picea amabilis* was well represented by a noble specimen some 40 feet in height. *Picea cephalonica* was full 60 feet high, and when flourishing as it was here is infinitely

superior to *P. Pinsapo*, to which it bears some resemblance. A magnificent example of *Picea nobilis* was 50 feet high, and there was some good *P. Nordmanniana*. *P. grandis* was also very handsome. Then among others was an *Araucaria imbricata* of about 60 feet with numerous cones, a *Fitzroya patagonica* full 18 feet high, and an equally fine *Saxe-Gothæa conspicua*. *Pinus insignis* was very healthy and flourishing, but it was not so fine as the Lamorran trees, and yet it was of no mean size, being quite 60 feet high; and there was a *P. ponderosa* about half that height. *Cupressus macrocarpa* was some 50 feet high, and many others were similarly fine.

Arriving at the garden we went first through the glass houses, and found plants of all kinds in superlative condition, a huge stove full of plants, every one a specimen—clean, glistening with health, and with a development of colour, form, and size such as one very seldom meets with. Fine-foliage plants were especially good. Such a lot of *Marantas*! which shall I choose? This *Veitchii* is surely the best. Ah! but

Fig. 13.—PENCARROW—THE ROCKERY.

look at this magnificent *fasciata*; its diameter exceeds 3 feet. And so we went from one to another in a state of bewilderment and delight, enjoying the rare sight fully, yet unable to dwell long over any plant. An alcove at one end of the stove had a novel and pretty arrangement of rocks interspersed with *Lycopods* and *Begonias*, and every part of the walls and pillars of the house was concealed by a close growth of *Ficus repens*. The beautiful *Anthurium crystallinum* was in as good condition as the other plants in this house; and in another—a stove aquarium—was a tank filled with *Nymphæas*, *Allamandas Hendersoni*, *Schotti*, and *Chelsoni* trained up the rafters all in full bloom, *Chelsoni* being decidedly superior to the other two. *Crotons* new and old, all well grown and splendidly coloured, were ranged singly upon a broad shelf around the sides, and the effect of this simple arrangement was chaste and especially enjoyable after the sight of so many varied forms and colours as were seen in the large stove. In a greenhouse *Lasiandra macrantha floribunda* was laden with bold clusters of its rich violet flowers. This is a valuable plant, flowering with equal freedom when planted out in a border and trained up a wall as it was, or confined in small pots, and its flowers both in form and colour are very beautiful. There were other plant houses containing *Fuchsias* and *Ferns*, and a range of

somewhat undersized vineries, the Vines being so much restricted in growth, or rather the growth is of necessity confined within such narrow limits that the fruit cannot have a fair chance.

A few steps from the houses brings us to the lawns and shrubberies, and one is impressed at the first glance with the ample expanse of fine turf tastefully broken by an occasional bed of flowers or specimen tree. The lawn near the house rises gently from it, and out in a central position a bold circular mass of *Cannas* with marginal rows of bright colours has a very happy effect. In another large detached bed are hardy *Heaths* in full summer beauty; in another are a brilliant batch of tuberous *Begonias*, such as *Froebeli*, *Chelsoni*, *Veitchii*, *intermedia*, *boliviensis*, and others, all thoroughly established and left here undisturbed the year round, a little cocoa-nut fibre only being thrown upon the surface to exclude frost in winter. This bed was very beautiful, and I strongly commend it as worthy of general notice, and as a bold and decidedly successful step out of the beaten track.

The flower garden proper is a huge sunken panel having an elegant design in scrollwork. It adjoins the house, and is sheltered on the west side by a clump of old *Beech* trees; and on the side is a rockery, a small portion of which is shown in

fig. 13, for it is very extensive, is bold in character, broken and picturesque—a high ridge with projections and detached masses advancing so far in front of it as to form all sorts of nooks and recesses containing Ferns, Heaths, dwarf flowering shrubs such as *Fuchsias*, *Berberis*, *Andromedas*. The rocks are not deposited in regular strata, but are arranged as a series of irregular peaks in imitation of the Dartmoor tors; and although extending so far, are so skilfully combined that the whole has an air of unity and accord. From the rockery walks wind through a grove of rare kinds of Ash trees said to form the finest collection of this genus in England, many of them having strikingly handsome foliage, onwards up a winding valley through which runs a stream having an appropriate growth of *Osmunda*, *Bambusa*, *Pampas Grass*, *New Zealand Flax*, *Gunnera scabra*, *Flags*, *Sedges*, and *Bullrushes* along and spreading outwards from its margins, many of the plants being huge detached specimens, the *Gunneras* being especially fine. *Rhododendrons*, too, are intermingled with them, and are found to increase in numbers as we ascend till the banks at length are clothed entirely with a compact growth of them, which runs upwards beneath the sweeping branches of high trees and onwards around a fine piece of water, where the banks are very high and steep, but covered in every part with *Rhododendrons*. The walks wind picturesquely around the water upwards to the crown and glory of the valley, a *Rhododendron* garden some two acres in extent.

Thus briefly have I sketched an outline of this charming place, and I only regret my inability now to enter more fully upon its details, for I regard it as one of the finest examples of landscape gardening in this country. Deciduous trees play an important part here, for besides the remarkable collection of Ash trees there is an equally fine one of Oaks and another of *Magnolias*. I also saw a Golden Chestnut (*Castanea chrysophylla*) 6 feet high among numerous other rarities.

I must not conclude without congratulating Mr. Jones, the very able manager of this fine place, upon the excellent condition of a garden of which he has reason to feel proud, and to acknowledge the courteous reception he accorded me.—**EDWARD LUCKHURST.**

NEW PLANTS AND FLOWERS.

LILIAM CORDIFOLIUM. *Nat. ord., Liliaceæ. Linn., Hexandria Monogynia.*—"It flowered in the open air in Kew Gardens in July of last year, and is the second that has been flowered in England, the first being with Mr. Noble at Bagshot many years ago. Of our continental correspondents Max Leichtlin, Esq., of Baden-Baden, from whom this plant was received, and E. H. Krelage & Son of Haarlem, have both cultivated it successfully. It is said to be widely dispersed through the Japanese islands, growing in shady mountain woods, but not to be anywhere plentiful, but it has been found also in the Kurile group."—(*Bot. Mag.* t. 6337.)

KOELESTEINIA GRAMINEA.—"A very elegant Guiana Orchid collected by Schomburgk, and described by Lindley in 1836 under *Maxillaria* from specimens procured by Messrs. Loddiges. Since that period the genus *Koelesteinia* has been established upon various species of *Maxillaria* by Reichenbach in 'Bonplandia.' All of them are South American, and natives of the mountain regions of Guiana, Venezuela, and New Grenada. Another *Demerara* species, *K. tricolor*, Lindley, is very closely allied to this, differing in the greenish sepals and petals which have no transverse band. *K. graminea* is a well-known plant in cultivation, and flowered in the Royal Gardens in January of the present year."—(*Ibid.*, t. 6338.)

ANTHURIUM TRIFIDUM. *Nat. ord., Aroidæ. Linn., Tetrandria Monogynia.*—"It is alleged to have been introduced through the 'Challenger' expedition from the Eastern Indian Archipelago; but no *Anthurium* is known from that region, nor a specimen corresponding to our plant in the dried collections made by the naturalist of that expedition. Dr. Masters, figuring it in the *Gardeners' Chronicle* (1876, ii., page 365), having only a leafy specimen to judge from, thought it might prove to be identical with *Philodendron Holtonianum*, Schott, of New Grenada. The nearest ally of which I have seen specimens is a plant which my colleague Mr. N. E. Brown, who has specially occupied himself with the study of living Aroids, identifies with *A. ochranthum*, C. Koch, introduced from Costa Rica. In this species the leaf is by no means so deeply trifid, nor the lateral lobes elongate and falciform as in our plant."—(*Ibid.*, t. 6339.)

OREOPANAX THIBAUTII. *Nat. ord., Araliaceæ. Linn.,*

Pentandria Monogynia.—"O. Thibautii is a native of Pine forests in Chiapas, a province of Mexico, whence I have seen specimens from Linden (No. 1651), and Ghiesbrecht (No. 147). It is very closely allied to, and perhaps only a variety of, O. *Xalapensis*, which has, however, much larger flower heads, with shorter stouter peduncles and rather broader leaflets. A third closely allied Mexican form from Orizaba has heads only a quarter of an inch in diameter on slender peduncles an inch long; and a fourth, collected by Seeman in Boquitte, has fewer flowers in the heads, distinct recurved styles, and much broader leaflets. O. Thibautii was received under this name from Verschaffelt in 1862, and flowered at Kew in 1869, and subsequently in the month of November."—(*Ibid.*, t. 6340.)

BESLERIA IMRAY. *Nat. ord., Gesneraceæ. Linn., Didymamia Angiospermia.*—"B. Imray is a native of the island of Dominica, where it was discovered by our excellent correspondent of nearly half a century's standing, Dr. Imray, and to whom we are indebted for both living and dried specimens, the former of which first flowered at Kew in 1862. As a species it is most nearly allied to the common West Indian *B. lutea*, L., which is also found in Dominica as well as in Jamaica, St. Vincent, and St. Lucia and Martinique, and which has petioled leaves. It is a glabrous erect herb, with smooth obtusely four-angled stems."—(*Ibid.*, t. 6341.)

RAINFALL AT MORPETH.

In your issue of January 3rd I notice in your Meteorological Observations by Mr. G. J. Symons the rainfall of 1877 at Camden Square, London, was 28.17 inches. You may imagine the downpour that we have had in this part of the country, disastrous alike to both field and garden produce, when I state that nearly 45 inches fell. It is a wonder that we had any Potatoes left after the drenching rains which fell during the last seventeen days of July and the month of August; truly, St. Swithin gave us his blessing. The only Potatoes I had free of disease out of twenty sorts were Suttons' Magnum Bonum, an excellent crop.—J. R.

ADVANTAGES OF EARLY PLANTING.

THESE may be briefly summarised as including more time, more work, more heat, more growing force, and in consequence a larger per-centage of success. It is obvious that the early planter has more time for his work than the late planter. Beginning towards the end of October he may continue planting till February; not that such an extension of the planting season into the new year is desirable, but he can afford to go about the work in a more leisurely manner than he who defers his planting till the new year. It is then too often done in haste and without that due regard for thoroughness which ought to distinguish such a solid and lasting operation as that of the planting of a tree for life. "Marry in haste, repent at leisure" is equally applicable to the planting of trees. Spurts are allowable at the oar or on the course, but trees planted in spurts mostly perish in the most leisurely and provoking manner. The early planter has also the selection of time in his power. It is an immense practical advantage not to be obliged to plant in unfavourable weather. The early planter may plant when it suits him or the trees; the late planter, who has much to do, must plant be the weather and soil what they may. Trees should not be planted in mud, nor during sharp frosts nor drying easterly winds. The first swamps or rots the roots, the second paralysed their power, and the last dry up the larger part of their vital juices. By starting early, making every possible preparation beforehand, and promptly seizing every opportunity that offers, the early planter will generally be able to keep abreast of his work and complete his planting in good time and in the surest manner to command success. The command of the old Earl of Haddington on his death bed to his son John, to "be aye sticking in a tree, Jock," has done perhaps as much harm as good, for while it cannot be doubted it led him and many other Scotch lairds to plant extensively, it likewise gave rise to much careless and slovenly planting, which was fruitful of many deaths and preposterously slow progress. Planting should be something more and better than the mere sticking of trees into the earth anyhow and almost at any time. The time is, in fact, a powerful factor in the operation; and the six weeks included in the last half of October and the whole of November is without doubt the most advantageous season for planting.

The idea that the stars in their courses fought for or against

the ancient warrior was as beautiful as it was sublime. That, however, was but the offspring of fancy or the creation of poesy; but it is a sober fact that the sun himself is ranged on the side of the early planter. The earth is still fairly stored with solar heat through October and November. Heat is the most active recuperative power in nature. Instinct and experience alike prompt us to keep our wounds warm. If we cut our finger we wrap it round with rag, not merely to exclude the air but to retain the heat. If anyone doubts that the heat is an element in the healing, let him try the experiment of exposing his next cut to the cold. He will not repeat the cold cure for wounds. The same care holds good with plants. Each newly planted tree has received some, it may be many wounds. It is impossible to transplant trees, however small, without mutilating or bruising few or many of their most delicate roots. The primary object of the planter is to get these wounds healed as quickly as possible. There is no healing power within reach equal to a covering of fine—that is, close-fitting warm earth. Treat the roots to this promptly and they begin to heal at once, and once the start is made the process of healing is soon and surely completed.

Trees are necessarily detached from the soil in the process of replanting. The old connection is severed, and a certain time must elapse before a new one is established. True, the roots are covered with earth, but this covering is merely mechanical, and the roots have no vital hold of the ground; they absorb neither food nor water from it. This interregnum in the close hold of the roots on the soil constitutes the danger of planting. While the roots remain detached the plant suffers in health and strength, in fact is in danger of dying. Hence the practical importance of making the period of detachment or root-isolation as short as possible. Solar heat is the great root-quickener that arouses them to a sense of their new position, and enables them to lay hold of and grow in the fresh soil of their new abode.

But supposing the solar heat to be flooded, frozen, or driven out by the cold rains, frosts, snows, or winds of winter, the injured roots will be deprived of their most powerful healer and only available stimulant to their speedy settlement in their new home. This is no matter of theory, but of actual experience and daily observation. Plant trees at the seasons here specified, the roots heal quickly and take a grip of the soil at once. Defer planting till January and the roots start slowly, often not at all in time to recuperate the trees, exhausted of their fluids by their bursting buds in the early spring.

This brings us to the third point in favour of early planting—more growing force. The roots are more active in the late autumn or early winter than at any other season. Few that have had much experience with trees or shrubs but must have noticed this. Lay trees in by the heels in November, and they will form a mass of new roots in a month or six weeks. Lay the same trees in during January and nothing like the number of roots will be formed. An examination of trees planted at the two seasons respectively reveals similar disparity of root-action at the two seasons. The cause of this may arise from the descending sap, if there is such a thing; or perhaps, more probably, from the residue of solar heat still stored within the fertile bosom of the earth. Probably, also, the winter is the special season for root-extension. During the summer, with the trees covered with leaves, flowers, or fruits, it may very well happen that the roots are chiefly engaged in forwarding supplies. Like parcels delivery companies they may then receive for and deliver to other parts of the plants chiefly or only. The season of falling leaves and naked boughs brings a partial rest or slackness in the collecting and delivery departments. What, therefore, is more probable than that this should be the season chosen by the roots for enlarging themselves and breaking into new ground against the augmented demands of the next season? Be all this as it may, it is certain that during November the roots of deciduous trees are in a state of abnormal activity, and the prudent cultivator will gladly avail himself of this augmented vital force as the most potent means at his disposal for promptly starting his trees in their new positions.

The early planter also gets more work done than the late one. Work here has also a double meaning. It is true the early planter gets more trees planted for less money than he that plants later. This is something, for planting is costly if well done, whether on a large or a small scale. But the trees themselves do better if planted early, and this is of the utmost moment. Trees thrive or stunt, live or die, very much in the ratio of the promptness of their root-making within the first

two months of the time of their planting. Plant in November, the roots will be in full growth before January, and the tree be safely established; plant in January, and the condition of the tree in March—the most trying month of the whole year—may be said to be at the mercy of a chapter of accidents, on which no one can rely with any certainty.

If there is any truth in these remarks, and no planter will deny that there is much, one last proposition follows as a matter of course, that the early planter commands the larger measure of success. This is abundantly proved by experience, the outcome of which may be summarised thus:—Plant early, the trees must thrive; plant late, they may live.—D. T. FISH. —(*Journal of Forestry.*)

NOTES ON VILLA AND SUBURBAN GARDENING.

HARDY CLIMBERS AND SCREEN PLANTS.—We are frequently receiving inquiries from correspondents to know the best climbers and screen plants suitable for covering both high and low walls for sunny and shady positions, and for north, south, east, and west aspects. This is not to be wondered at when we notice the rapid increase of villas in the suburbs of our large towns. Walls are "red and bare" or harsh and rigid to the eye unless the surface is clothed with foliage or flowering plants suitable for this purpose. As the present time is favourable to the planting of such we give a selection and describe them as clearly as possible, and at the same time suggest the positions best suited to promote a rapid growth of the plants, without which they cannot produce a satisfactory effect.

Ivy.—For covering unsightly or boundary walls or for a north aspect there is nothing to surpass the numerous varieties of Ivy, amongst which are such a diversity of colours and sizes and forms of foliage that a good collection will be found highly interesting "all the year round." *Hedera dentata* is the largest-leaved Ivy in cultivation. We recently measured a leaf of this that was 8 inches long and 6½ inches broad. It has a very long leafstalk, and its hard leathery foliage stands out boldly and effectively. *H. Ragnieriana* is another bold and effective kind with magnificent large glossy heart-shaped leaves. It will rapidly cover a large space of wall with its robust growth; but perhaps the most useful for all purposes are *Hedera canariensis* and *c. latifolia maculata*; this last is a handsome marbled-foliaged variety of *canariensis*. They are both of very free growth, quickly covering the wall or trelliswork against which they are planted. *H. azorica*, *sagittifolia*, and *taurica* are also very useful; the last named has much-divided small and neat distinct leaves. There are also several other very pretty variegated sorts, such as *H. aurea*, *argentea*, and *elegantissima* which do not grow quite so fast as the foregoing, but are indispensable if a collection is aimed at, and are very useful for covering buttresses and small prominent positions, the more robust growers being planted to cover the broadest spaces. The green varieties of Ivy delight in rich soil, which induces their rapid growth; but to the golden and other variegated sorts rich soil is detrimental, for if forced into exuberant growth they are apt to sport from their variegation; to obviate this we advise mixing stones, lime rubbish, and the like amongst the soil prepared to plant in. Generally speaking Ivy loves shade and clings tenaciously to most walls, but in the first instance the shoots, especially of the larger varieties, require nailing to their positions. Where Ivy has long been established, the shoots having been allowed to grow across each other until all has become a dense mass, it will be advisable during March or early April to give the whole surface a severe clipping with the garden shears; for a few weeks afterwards it will have a bare and shabby appearance, but this will soon disappear, and the young shoots will give a lovely green surface that will be pleasant to the eye the remainder of the year. The clipping will also decrease the weight of the Ivy and prevent it coming down *en masse*, which it not unfrequently does during rough and wet weather.

Ampelopsis hederacea (Virginian Creeper).—This is one of the most ornamental and rapid-growing plants we have. It flourishes admirably on a north wall; in fact it is a most accommodating plant, thriving everywhere even in the heart of London, running around and over balconies, and draping them and other structures during summer with festoons of its tender young shoots. In the autumn the leaves turn to a brilliant crimson hue, which for a short time is very effective. We have it growing intermixed with Irish Ivy and covering the wall of a residence 40 to 50 feet high. *Ampelopsis Veitchii* (*tricuspidata*) is very suitable for walls, and is as remarkable for its elegance of growth, its refined and graceful appearance, as for the tenacity with which it clings to the object against which it is planted. It will thrive well in a north position, but a warmer aspect brings out better the brilliant colour of its leaves in the autumn. We strongly commend this plant to our readers.

Crataegus Pyracantha.—This and *C. Lelandii* are most desirable plants for cold north aspects, and when in fruit are highly at-

tractive. The leading shoots should be trained upright, and the side branches horizontally. Although the plants named are well suited for cold north shady positions the greater part of them will also be equally suitable for an east wall; but to this position the following may be added, which will give a greater variety. *Clematis flammula* is not only a very profuse bloomer in early spring but is very fragrant and sweet-scented; this and *Jasminum officinale* will ramble to a great height. *Cydonia japonica* is a deciduous shrub and is best suited for low walls and screens, its brilliant flowers opening so early in the year make it very welcome; and fit companions for it are *Berberis Darwinii* and *Cotoneasters microphylla* and *Simmonsii*, all very neat-growing evergreen shrubs. The common *Euonymus* may be planted with advantage near the sea and in very exposed places. The glossy appearance of its foliage and the compactness of growth make it very valuable for low walls. There are several variegated forms of the *Euonymus* which are extremely attractive, but we should prefer planting these on the west sides of a low wall.

For south and west positions the following are all suitable, some flowering in midwinter, others throughout the remainder of the year. The remarkable fragrant deciduous shrubs *Chimonanthus fragrans* and *Jasminum nudiflorum* are in flower now, the former having curious pale yellow flowers and the latter bright yellow, bearing profusely on the bare twigs, the foliage following after blooming. Most of the *Ceanothus* are very beautiful; their dense habit and free-blooming properties render them great favourites, particularly *C. azureus*, *Gloire de Versailles*, *dentatus*, *divaricatus*, and *rigidus*. All these and *Magnolia grandiflora exoniensis* flourish well in the warmest and most sheltered positions; while *Clematises rubella*, *Jackmanii*, and *lanuginosa* will cover the taller and less protected quarters. These *Clematises* flower the better for pruning rather closely in the spring and by the roots receiving a liberal dressing of decayed manure. *Escalonia macrantha* is a very fine species, and in damp places blooms very freely. *E. rubra* is also deserving of a place. *Elaeagnus aurea maculata* is a very beautiful variegated shrub for a low wall, and *Garrya elliptica* is admirably suited either for high or low walls; its charming evergreen foliage is very pleasing during the summer months, and in the winter it is profusely laden with long catkins which are both elegant and conspicuous.

Many *Roses* are also very suitable for training against walls and covering trellises, a selection of which and their after-treatment we must defer until our next.

WORK FOR THE WEEK.

KITCHEN GARDEN.

POTATOES where stored in heaps should at once be spread out in sheds or other positions safe from frost, especially the early varieties, which, if the shoots are so long as to necessitate the removal of the first growths, are apt to become blind, causing serious disappointment. We consider the removal of the first sprouts weakens the sets, and is not without its detrimental effect upon the produce. All, especially the early kinds, should be kept cool (the cooler the better provided they are safe from frost), so as to secure them with the first growths half to three-quarters of an inch long by the time of planting. Early kinds packed in shallow boxes, eye ends uppermost, and placed in a moderately light place with a temperature of 45° to 50°, will make short and sturdy sprouts by planting time, which should be well hardened off before being placed in the soil. Placing them in moist houses not only forwards the sprouting but the formation of roots, which speedily succumb to the dry air at planting time, which, of course, is injurious. Onions, where kept in close rooms or cellars, will be commencing to grow. Remove them to a cool airy shed. If strung and suspended they keep sound in such a position for a very long time.

FRAMES AND PITS.

Continue making beds and planting Potatoes in proportion to the demand. A little Celery may be sown in pans of rich soil placed in a warm pit close to the glass, the seed being very thinly covered with fine soil. Incomparable (*Sandringham Dwarf White*) is one of the best, and is not so liable to run quickly as most kinds. Sow Tomatoes if not already done, repotting those strong enough as they fill the pots with roots. Carrots, Lettuces, and Radishes require air on all favourable occasions to keep them from becoming drawn in a young state. A good supply of Mint should now be taken up and placed in pots or boxes and assigned positions in a vinery or other warm house, also a few roots of Tarragon. Sow the customary small salading once or twice a week.

Cucumbers and Melons.—If there exist no means of raising plants for planting in frames a bed should be made at once of well-sweetened dung so as to receive a one or two-light frame; but where there are forcing houses Cucumber plants for the first bed may be raised without the trouble of a bed purposely made for raising a few plants. Nothing is gained by early sowing and planting of Cucumbers and Melons in pits or frames solely heated by fermenting materials, owing to the difficulty of maintaining a brisk heat at the time the plants should come into bearing. The early part of February is quite early enough to plant Cucum-

bers, the bed having been made up a week to ten days previously of well-sweetened hot dung and tree leaves in about equal parts, which admixture produces a steadier and more lasting heat, that of dung alone being often violent and of but short duration. Beds 6 feet high at the back and 5 feet in the front will be necessary for the first crops. Medium-textured loam with the turf reduced is the best soil for Cucumbers without any admixture, a hill being raised in the centre of each light with a flattened top, the depth of soil 10 inches, and the surface of the bed covered with an inch of soil. If the heat be violent an inverted flower pot inserted half its depth in the dung, a hollow being made to receive it where the hillock is to be raised, will prevent the soil becoming too hot for planting, which should not be done with a higher bottom heat at 6 inches depth than 90°. The soil should only be moderately moist, as a wet soil or over-watering will cause the decay of the stems. Top heat 70° to 75° to be maintained by placing linings of hot dung as required to the sides of the bed and frame. Place one plant in a light and down to the seed leaves within an inch. The *Sion House* class having many representatives, *Munro's Duke of Edinburgh* being one of the best, are good for everyday use, and *Tender-and-True* is excellent for any purpose. Of Melons there are now so many that selection is difficult. *Eastnor Castle*, *Golden Gem*, *Read's Scarlet-flesh*, and *Meredith's Cashmere* are good; but we do not advise Melons to be sown for planting in frames as yet, as the high temperature, in the absence of light and air, induces weakly growth, whereas sturdy growth and thick leathery leaves are wanted for the production of heavy fruit, which is always the thickest in flesh and highest in flavour.

Flower Garden Stock.—Look over the plants frequently, removing any mouldy or decayed parts, and water carefully, especially succulents. An estimate of the quantities of the plants required should be made. Plants which are increased by cuttings should be placed in a higher temperature and moister atmosphere. *Ageratum*, *Verbenas*, *Lobelias*, &c., soon afford a quantity of cuttings. *Alternantheras* if potted in rich soil and given a temperature of 65° to 60° at night, 70° to 75° by day, also *Coleuses* and *Iresines*, will soon afford an abundance of cuttings. Sow seeds in a hotbed of *Canna*, *Ferdinandia*, *Nicotiana*, *Melanthus*, *Eucalyptus*, *Ricinus*, and other subtropical plants where means are provided for growing them on without crowding. They should be strong plants at planting-time and well hardened-off. Sow also seeds of succulents, such as *Echeverias*, *Sempervivums*, and *Sedums*. *Mesembryanthemum cordifolium variegatum* does not always come true from seed; cuttings strike readily in a rather dry heat of 65°. The fleshy leaves of *Echeverias*, *Cotyledons*, *Pachyphitons*, *Kleinias*, &c., may be detached and inserted in sandy soil, and they will soon root in a dry heat.

HARDY FRUIT GARDEN.

Take the first opportunity to complete the planting of any trees or bushes yet remaining to be done, the ground having previously been trenched and, in the case of new plantations, drained. We not unfrequently see orchard trees with their stems and branches up to the small twigs covered with moss and lichen, and the sward beneath them for the most part moss intermingled with thin wiry grass. Draining in most instances would be beneficial, as no tree will long thrive and be profitable with water lodging nearer the surface than 4 feet. Any excess—and all above the soil's power of retention is that—should be removed by thorough drainage. Moss and lichen upon the trees are readily destroyed by dusting them in every part whilst wet with quicklime, a practice which is equally applicable to trees in gardens down to Gooseberry bushes, which not unfrequently become clogged with moss, &c. Newly planted trees should be securely staked and mulched over the roots, deferring pruning until the buds commence swelling. Moss not infrequently arises from sterile soil; a top-dressing in the case of orchards of rich compost and lime, one ton of lime to six of compost, would do much to improve the soil, and ultimately the trees, if spread on the surface of the ground so far as the branches of the trees extend. Orchard trees having the heads very much crowded with weak and dead wood should have the dead cut out and the weak crowded wood thinned, particularly the inner branches and those crossed and entangled. It should, however, be done with moderation, as a too severe thinning will only result in the production of strong shoots or much young wood, a great portion of which will need to be removed.

FLOWER GARDEN.

In addition to the usual mulch given to *Roses* in early winter a little hay, or, what is better, bracken loosely woven in among the heads of standards and placed over and among those of dwarfs, will have a tendency to save them from injury by severe frost, but it should only be employed in that case, and not be removed until a general thaw. The wet and cold of last year has left the wood very sappy and unripe. Tree *Pæonies*, *Tritomas*, and similar plants are not only the better for a mulch of some enriching material over the roots, but a top covering of some dry material in severe weather is advantageous. Protection must be given to beds of *Anemones* and *Ranunculuses* in severe weather. *Pinks*, *Carnations*, *Pyrethrums*, and *Delphiniums* are much relieved by

slugs; a sprinkling of soot over them will render the plants obnoxious to them. In the case of Pyrethrums and Delphiniums remove the soil from the crowns, sprinkle with soot, and cover with ashes; also Hollyhocks and other plants liable to suffer by wet as well as slug attacks. Ground intended for Dahlias, Hollyhocks, and all plants of strong growth should be deeply trenched and liberally manured, leaving the surface as rough as possible to allow of the action of frost. Beds for summer-bedding plants to be trenched and moderately manured, especially for flowering plants, those for foliage plants requiring a rich soil.

FRUIT HOUSES.

Vines.—Anything approaching to a close atmosphere is highly prejudicial to the formation of stout short-jointed shoots and thick leathery leaves, therefore admit air when the weather permits. Close the houses early as there is great difference between sun and artificial heat, allowing the temperature to advance to 80° on fine afternoons, and to fall to 60° during cold nights. Disbudding to be attended to so soon as the bunches show, leaving the best. It is a good practice to disbud gradually. We leave two shoots to a spur, one only being allowed to fruit, the other being retained, which induces an extended root-action and induces a greater supply of nutriment to the bunches. Remove loose and duplicate bunches, stopping the shoots at two joints beyond the bunch, but not until the leaf stopped to is half developed. Thinning may be commenced as soon as the berries are the size of small peas. This, however, will be subsequently alluded to. See that the outside border is not allowed to decline in temperature by lack of timely additions to the fermenting material.

Peaches and Nectarines.—The trees in the early house will after the fruit is all set require syringing morning and afternoon in bright weather; during dull days syringing in the morning will be sufficient, not omitting to damp the floors frequently when the syringing of the trees is omitted. Disbud the young shoots cautiously, a few at a time, so as not to lessen the root-action and cause the incipient fruit to drop. Let the temperature be 60° to 55° at night, and 60° to 65° by day from fire heat, rising to 70° to 75° from sun heat. The houses closed early in the month will now have the trees in flower. Discontinue the sprinkling overhead, but the floors should be damped once or twice a-day according to the weather. The flower buds in the latest houses are swelling fast; keep such cool by free ventilation, avoiding, however, actual frost. If aphid appear fumigate with tobacco.

PLANT HOUSES.

Stove.—Gesneras of the zebrina type having flowered should have a position near the glass, and no more water than to prevent excessive flagging. Any plants coming into flower to have a light position and not allowed to suffer by want of water. Weak liquid manure is beneficial. The bulbous section, such as *G. Donckelaari*, if any were dried-off in autumn may now be started, potting them similar to *Gloxinias*, and placing them in a warm yet light position. *Nagelias* and *Eucodonia*s not to be dried off too quickly, but to have light and airy situations with water to keep the foliage from flagging. Those in flower to be well supplied with water. Some *Achimenes* may now be started in broad pans, and after they have made an inch or two of growth be lifted carefully and transferred to the flowering pots, pans, or baskets. *Caladiums*, if wanted early for decorative purposes, may now be started, and as they are most acceptable in small pots, as 6 or 8-inch, the small corms should be employed preferably to the larger corms, which should have pots proportionate to their size. *C. argyrites* is still one of the best for decorative purposes. *Epiphyllums* which have ceased flowering to have a lessened supply of water and light position in an intermediate or warm greenhouse. *Poinsettias* also to have a season of rest after their beauty is over by placing them on a shelf near the glass, watering very sparingly until the leaves are shed. *Centropogon Lucyanus* to have a rest after flowering, and being cut back a little and placed near the glass, not allowing the roots to become too dry. *Eranthemums* and *Euphorbia jacinthiflora* having been cut out or of flower to have plenty of light and very little water, but the foliage of the former to be kept from flagging, and when the *Euphorbia* is leafless cease watering almost entirely, but see that the wood does not shrivel.

TRADE CATALOGUES RECEIVED.

James Carter & Co., High Holborn, London.—*List of Novelties and Collections of Seeds.*

William Bull, King's Road, Chelsea.—*Catalogue of Select Flower, Vegetable, and Agricultural Seeds.*

Hooper & Co., Covent Garden, London.—*Spring Catalogue of Seeds, Plants, and Garden Requisites.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (A. A. Fruit).—The "Vine Manual," free by post if you enclose thirty postage stamps with your address. (*Col. R. S. S.*).—*Indoor Gardening* we think will afford the information.

NOISE IN HOT-WATER PIPES (R. C. H.).—It probably arises from air bubbles passing through the water. Affix an air pipe at the highest point of the hot-water pipes to induce a better circulation.

NIGHT SOIL (J. Davies).—It is one of the most fertilising of manures. Quicklime does not reduce its value.

PLANTING POTATOES (Carlos).—If you plant the sets and rows 18 inches apart you will require about 48 cwt. of Potatoes, a single eye to each set, and each set weighing 2 ozs.

MEALY BUG (H. S.).—The proportions of ingredients you mention are correct.

VINES NOT STARTING FREELY (M. D.).—You have possibly been too generous in applying heating material to your Vine borders. You have probably covered them too soon and kept them too warm. It is not in the nature of Vines to make roots actively before top growth has commenced. Fermenting manure and leaves promote the formation of roots near the surface of the borders, and the practice is a good one if properly carried out. We never place the material on the borders before the period when the house is kept close. We think the practice of covering the borders with "hot manure" two months before starting the Vines decidedly wrong. We have observed that Vines thus managed always break weakly. You had better let the heat of the fermenting material decline, and slightly increase the temperature of the house. You have probably weakened your crop for this season, but the Vines will eventually recover their strength as the season advances.

CUCUMBERS UNHEALTHY (A New Subscriber).—We fear your plants are attacked by the disease. We advise you to remove all the soil and replace with fresh, obtaining also fresh seed for the raising of healthy plants. Those you have can never be profitable, although perhaps they may produce a few fruits, until your young plants are advanced for continuing the supply. There were traces of red spider on the leaves, but the insect attacks had not been serious.

SELECT ROSES (R. H. A.).—The following are twelve good hardy climbing Roses for a north wall in Cornwall:—*Gloire de Dijon*, *Céline Forestier*, *Fulgens* or *Malton*, *Climbing Devonians*, *La Biche*, *Rêve d'Or*, *Donna Maria*, *Sir Joseph Paxton*, *Félicité Perpetue*, *Belle de Bordeaux*, *Climbing Jules Margottin*, *Cloth of Gold*. The last, though an uncertain bloomer, will often flower well on a north wall. If the wall is high it would be best to plant one of the above rampant climbers every 8 feet, with a Rose of shorter growth between, allowing the former the upper half of the wall and the shorter growers the lower part. This plan gives variety and clothes the lower stems of the climbers, which are apt to get naked and scrubby. There are many of the strong-growing Hybrid Perpetual Roses suitable for this purpose, as *Paul Neyron*, *Glory of Waltham*, *Général Jacqueminot*, *Boule de Neige*, *Princesse Camille de Rohan*, *La Souveraine*, &c. The dwarf Briar and *Céline* stocks are best for the Tea and Noisette varieties, and the *Manetti* for the Hybrid Perpetuals.

GROWING MUSHROOMS (J. C. G.).—The bulk of the material must consist of horse droppings, with a little half-decayed stable litter intermixed. A third of leaves may be added, and a tenth of loam, the whole being thoroughly mixed and pressed firmly into a bed not less than a foot in thickness. When the heat is declining, not rising, spawn may be inserted when the temperature of the bed is between 75° and 80°. Press lumps of spawn about the size of walnuts into the surface of the bed and about 8 inches apart. In about a week afterwards place on 2 inches of good loam and beat it very firmly. In about six weeks after that, if the bed and temperature are right and the spawn good, you may expect Mushrooms. The leaves you name are only useful for mixing with the horse manure.

FORCING ASPARAGUS (Idem).—There is no better plan than placing the roots closely together in a frame on a hotbed of manure, where the heat is from 80° to 70°, placing them on a layer of soil and covering the crowns 3 or 4 inches deep with light soil. The top heat of the frame should not exceed 60°. It may be forced also in boxes in any light well-heated structure.

WATERING INSIDE VINE BORDER (M. D.).—As your Vine border was never watered during the time the fruit was colouring, it is not surprising that red spider and thrips became so plentiful, and unless careful measures are taken to eradicate them you may depend on having to contend with a much greater force of these pests this season; but this will be much easier done than repairing the injury which the Vines will have sustained through having been "dust dry" at the roots for "some months." This is the worst treatment they could be subjected to. Lose no time in pruning, cleaning, and washing the canes thoroughly with soft soap and water. Remove a few inches of the dry surface soil from the border, and replace it with a rich mixture of loam and decayed manure; then give sufficient water to thoroughly drench the whole border. As it will be some time before the dried half-dead roots can get into proper action, we would advise you to start the Vines into growth very slowly. Water copiously throughout the growing season, as well as when the fruit is colouring, and after that never let the soil become so dry that if a tender-leave plant was planted in it the

leaves would droop for want of water. Your other question will be answered next week.

CLERODENDRON BALFOURI TO FLOWER IN AUGUST (J. E.).—The plants having "just been potted and growing fast" will require to be well supplied with water and to be kept in a brisk moist heat until the growth is complete, and should then have water sufficient only to maintain the foliage from flagging, lessening the supply gradually, affording a light and airy position so as to induce the thorough ripening of the wood. The plants ought to be at rest by the middle of May, and should be kept quite dry until the middle of June, not, however, allowing the wood to shrivel, when the plants may be repotted, merely rectifying the drainage and loosening the sides of the ball and giving a pot 2 inches larger in diameter; or, if potting be not required, remove a portion of the surface soil and replace with fresh. Place the plants in a brisk moist heat and supply them well with water and with weak liquid manure when the shoots are an inch in length, and provided the wood is well ripened your plants will be masses of bloom in five to six weeks. We have half a dozen plants, and are never without flowers of this very useful plant.

BUCHARIS AMAZONICA (Idem).—For invigorating your plants pot them in rather strong or yellow loam, plunge the pots in bottom heat (85° to 90° at the bottom of the pots), and water with liquid manure liberally, but not in very strong doses. Top heat should be 75° to 70° by day, rising to 80° or 85° with sun, 65° to 60° at night.

CAMELLIAS NOT FLOWERING (A Constant Reader).—The non-flowering is a consequence of too free growth, the border being probably rich and loose, and the wood strong and not well ripened. It is not infrequent for plants planted out to grow very vigorously for a few years, which is none the worse for them in after years. We should admit air very freely after the growth is complete, and keep the atmosphere rather dry so as to induce the well-ripening of the wood, and when the buds are set keep the house cool. The plants starting into growth before flowering is due to their vigorous root-action and the high temperature maintained, and probably close atmosphere; 50° to 55° from fire heat is much too high for Camellias. Ours are kept in a temperature of 45° to 50° by day and 45° to 40° at night, and have flowers from November to April inclusive, they being finer this year than usual.

TRANSPLANTING LARGE GOOSEBERRY AND CURRANT BUSHES (J. S.).—The heads of the Currants should be drawn together and secured in bundle-like form with string, being careful not to break the branches, the Gooseberries to some extent being amenable to the same practice, but to a lesser extent owing to the lesser flexibility of the branches. Buses of the age you name will require to have a trench taken out 2 feet from the stem all around and below the roots; from the trench you will need to work toward the stem with a fork, removing the loose soil from the roots until within a foot from the stem, where a spade should be used to lift the bushes, inserting it all around beneath the roots in a slanting direction, so as to cut any perpendicular roots. If you can move with some soil adhering to the roots it will facilitate their establishment in their new quarters. Spread out the roots in planting, working in the soil among them, using moderately rich soil, mulching over the roots on the surface of the soil with short litter, and take the earliest opportunity after the middle of February to thin out the branches and cut back any irregularities of growth to compensate in some measure for the loss of roots consequent upon removal; in other words, pruning should be more severe than if the bushes had not been removed.

CECLOGYNH CRISTATA (Constant Subscriber).—As your plants made "new and fine bulbs last year," their not flowering is due to the growths not having been well ripened. Afford them more light this year after the growth is complete and give a thorough rest. It is similar with the Dendrobium nobile. Have the growths well ripened, and afterwards keep dry and cool. Orchids in plant houses are often not satisfactory from the plants being kept at too great a distance from the glass, in positions shaded by climbers or other plants, and kept too moist when at rest, which causes growth instead of flowering. The temperature is right.

TUBEROUS-ROOTED BEGONIAS (E. S. W.).—We hope shortly to publish some hints upon the cultivation of this very desirable and much-improved class.

CULYERWELL'S PROLIFIC MARROW PEA (W. R.).—Apply to Messrs. James Veitch & Sons, Royal Exotic Nursery, King's Road, Chelsea, London.

HEATING A SMALL GREENHOUSE (W. H. Stafford).—Employ a fire rather than a petroleum stove.

BONE MANURE—COCO-NUT FIBRE REFUSE (W. S.).—Crushed bones may be mixed beneficially with the soil in which Cucumbers are grown. Coco-nut fibre refuse will not supply the place of leaf soil; it does not decay fast enough; it is, however, very valuable for propagating and plunging purposes.

PLANTS FOR A RIBBON BORDER (A New Subscriber).—For your border with three rows you may have an old but beautiful combination of Golden Feather Pyrethrum (yellow), Lobelia speciosa superba (blue), and Amaranthus melancholicus ruber (rich crimson), all readily raised from seed, and all coming into full beauty early and lasting well into autumn. Then there are Cineraria maritima and Cerastium tomentosum, both well-tried plants with pearly-grey foliage; the greyish-blue-flowered Ageratum Tom Thumb and Imperial Dwarf; Acacia lophantha, with elegant foliage; Cannas too making a fair display the first year from seed, as do such sub-tropicals as Ricinus Gibsoni and sanguineus tricolor, Solanum pyracanthum and S. Warsceviczii, also Ferdinandia eminens, Melianthus major, and Wigandia caracasana; but we must caution you not to attempt the culture of such plants in an exposed situation, shelter from wind being indispensable to the protection of the large delicate foliage, which a single storm may ruin for a season. Portulacae, Petunias, Zinnias, Godettias, and Philox Drummondii are all so gay, so variable in colour, form such compact cushion-like masses, are so easily raised, and so admirable withal that they cannot lightly be set aside, and under good culture are calculated to worthily fill beds and border, however prominent the position may be.

DESTROYING SLUGS (E. R.).—Where they are so numerous as in your case we doubt if you can apply anything more safe and effectual than a mixture of lime and root to your young Cauliflowers; but it must be applied frequently and at the right time. It is little use dusting the plants in the daytime when the slugs are safe in their haunts. We think if you apply the mixture frequently and liberally during mild nights when the slugs are feeding that you will save your Cauliflowers. Guano will kill slugs, but it must be used with caution, and is not applicable in your case. Large greased cabbage leaves and heaps of bran and grains will attract numbers

of slugs, which can be caught and destroyed; but the "traps" must be examined very early in the morning. A brood of young ducks would be very valuable in your garden.

PLANTING MARCHEAL NIEL ROSE (A. R. C.).—Plant your *Maréchal Niel* immediately. It answers best with us on the common Briar stock.

HARDY AURICULARS (Idem).—The *Alpine Auricula* is what you require, and plants can be had from most nurserymen, or you may raise them from seed. It should be sown early in March in fine rich gritty soil in pans placed in such heat as a vinery at work or an ordinary hotbed affords, and the seedlings potted singly so soon as they are large enough, and be kept growing briskly under glass till the roots reach the sides of the pots, when they may be gradually hardened and then planted out in open beds or borders.

PLANTS FOR THE BACK WALL OF A VINERY (Idem).—There is too much shade in such a position for Roses, but Camellias answer admirably, clothing the walls with perennial greenery, affording a considerable supply of cut bloom and not affecting the health of the Vines in the slightest degree.

GRAFTING OLD APPLE TREES (Notice).—Old Apple trees if healthy may have the branches shortened and grafted with considerable advantage, but when traces of disease and decay are combined with barrenness the trees should be destroyed. The process of grafting should be applied to the branches and not to the stems, so as to turn the new growth to account for the production of fruit quickly. Thus much generally. In your particular case of huge old trees in a small kitchen garden we should be disposed to destroy all the old barren trees, to retain, at least for a time, those which are good kinds and still afford some fruit, and to plant some strong pyramids, which would soon bear fruit, and not trench upon space required for vegetables, as the old trees must now do. Here are a dozen cases of excellent free-bearing sorts for dessert and kitchen use. *Dessert:* Devonshire Quarrenden, Joanneting, Kerry Pippin, Ribston Pippin, Cox's Orange Pippin, Margil, Nonpareil, Kaddleston Pippin, Court of Wick, Adams' Pearmain, Court Pendu Plat, and Pittaston Nonpareil. *Kitchen:* Keswick Codlin, Duchess of Oldenburg, Lord Suffield, Manks Codlin, Collins, Cox's Pomona, Nelson Codlin, Emperor Alexander, Alfriston, Bedfordshire Foundling, Gloria Mundi, and Nonesuch.

OLEANDERS SHEDDING THEIR FLOWER BUDS (A Notice).—Oleanders established in well-drained pots cannot easily be over-watered. Any fault in the drainage would prove fatal to the flower buds, and we suspect it has been so in your case. You may cut down the branches to within a few inches of the pots, and when the buds commence swelling shake most of the old soil off the roots; give plenty of drainage. Repot in rich gritty soil, give water freely and regularly, keep the foliage clean, let the plants have as much light and air as possible, and although you have only a window for them, yet the new growth will yield some fine clusters of flowers. We have seen such window plants exhibited in very creditable condition.

BOX HEDGE (A Country Vicar).—The Box has such a mass of roots that you may employ plants for your hedge of any size from 1 to 6 feet, the only objection being the very considerable additional cost of large plants. A foot apart is quite close enough for the small size, and the larger ones should have a proportionate amount of space. Plant now, or as soon as soil and weather prove favourable. Holly would make a better fence against sheep than any other evergreen.

HYBRID PERPETUAL ROSES FOR WALLS (Idem).—Lord Raglan and Madame Clémence Joigneux are hardy and vigorous. Glory of Waltham is also a good dark variety for covering a wall.

RAISING CLEMATIS FROM SEED (John Brettell).—There are two ways of doing this—in pans placed in a greenhouse or vinery, or under a handglass upon a warm border. If your space under glass is much restricted the latter method will be best, especially as the seed does not always vegetate quickly; and we have found the wild *C. Vitalba* to spring up from seed much sooner than garden hybrids. This tendency to vegetate slowly leads us to avoid subjecting this seed to a strong heat, from the great risk of its becoming rotten when left long in hot moist soil.

SHRUB SCREEN IN A COLD DAMP DISTRICT (E. S.).—There is no better shrub for your purpose than the Holly. The common form, *Ilex aquifolium*, would answer, as would also the more green form, *I. tortuosa*, with which might be mingled an occasional plant of the rich yellow-variegated variety, Golden Queen. Plant these for a screen, and enrich the front of it with Rhododendrons.

BLACK CURRANTS BARREN (J. K.).—The early flowering of your Currants is very unusual. Destroy the whole of them, they are worthless, and plant Black Naples and Lee's Prolific Black in equal numbers.

NAMES OF PLANTS (J. B.).—*Saxifraga hypnoides*. (*M. D. D.*)—*Medicago Helix*. (*A. A.*)—We think *Iris fastidiosa*, but should see a flower.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

MANAGEMENT OF PASTURE AND PARK LAND.

UNDER this heading we propose to refer to all kinds of permanent grass land, including meadows, parks, upland pasture, and chalk downs. We may venture to say that no land in England is so much neglected as the permanent pastures. In the majority of the grazing districts few persons ever think of manuring grass land, but prefer to take all they can get from it whether little or much; and it is a great reproach to agriculture that the arable land should receive all the manure made on the farm whilst the pasture receives none at all. We therefore think that in letting land conditions should be made for the manuring a portion of the pastures every year either by dung and compost, or by guano or nitrate of soda and superphosphates according to the nature of the soil. As an instance of the state of much of the park lands of the country, we were once walking across a gentleman's park

with the proprietor, and we were asked what was the cause of so much moss which appeared on the surface. Our reply was that the growth of moss was the last effort made by Nature to clothe the land, it not being rich enough to bear grass. This remark was intended to make an impression on the mind of the owner, and it did so, for soon afterwards the park was manured both with guano and a dressing also of yard manure and compost, since which the moss has entirely disappeared, and the pasture bears abundant crops of grass both for hay and feeding. We would further remark that, on the home farm of the property alluded to, at our suggestion the plan is to put all the made dung and all the earthy materials that can be obtained upon the park land, and manure the arable with artificial manures only, such as guano, nitrate of soda, and superphosphate. Nothing that will rot is ever allowed to be burned upon this farm, but is carefully heaped with dung and earth for manure. Even couch grass is carefully preserved, and sometimes laid out on the pasture direct from the fallow field, and we have often noticed that it has equalled the effect of dung in improving pasture. This we account for by the earth which is connected with roots of couch; the latter, being drawn into the land by worms, opens and benefits the land in that way. The permanent pastures of the kingdom occupy every kind of subsoil—stone, chalk, gravel, clay, peat, sand, marl, &c., and of course these various soils require somewhat different treatment. Some of the nicest pastures for sheep and cattle are found upon the stone brash in various counties, and perhaps no pasture requires less done to it than this, the herbage being always sweet and requiring only artificial manures occasionally. Chalk hill pastures, commonly called downs, have been generally ill-used from time immemorial, the practice being to feed with sheep in the summer and fold them on the arable land at night time, thus robbing daily the pasture which was already too poor to bear anything but the most scanty herbage. We know, however, of a few instances where farmers manage better, and manure the land, waiting until there is grass enough to fold off with the sheep, which receive cake and remain on the pasture night and day; thus the grass is consumed in season, and manure enough left to insure a better and improving crop in the future. Guano and nitrate of soda we consider the best manure for chalk downs or any grass land resting on chalk, as some park land does in the southern and eastern counties.

Pastures resting on gravel are about the most difficult to improve by ordinary means of any we know, because they suffer so much from drought in dry seasons. They should, therefore, receive dressings of dung and earthy compost, in order to increase the depth of soil. The herbage on this land is always fine and sweet, and will, therefore, bear the stimulating effect of nitrate of soda and common salt. It sometimes occurs that these soils are sour, and grow sorrel and other weeds, indicating want of chalk, and where this can be readily obtained it should form part of the compost, being mixed beforehand with earth, &c. If chalk is not easily obtained lime should be mixed with the earth instead. Clay-land pastures vary so very much that it is difficult to treat them all alike with advantage. Some of the very best pastures we know of in the vale of Aylesbury and other parts of the kingdom do not require any manure if really well stocked and properly managed in other respects, for they will keep and feed-off fat a bullock and two sheep per acre without oilcake or any artificial food. Now, much of this land is very wet in the winter months, and will not bear the tread of the cattle except in spring and summer. We have known draining done in such soils, but it has ruined the pasture, inducing the land to crack open in wide fissures, the grass dying away in dry weather; and our experience induces us to believe that no grass land should be drained if it is free from rushes. This is our test. Some of these rich pastures through neglect are often found to produce large tufts of coarse grass commonly called hassocks. These should always be cut-up with the turf-cutter or sharp spade in the month of March, not burned into ashes, but used instead of straw in the cow houses, and then rotted into dung; a little seed sown over the vacancies will soon take the place of the useless and damaging hassocks. The principal cause of the rich clays being so productive is the potash they contain, and in many instances it will be desirable to have the subsoil analysed, because the appearance of the rich and poor clays being so much alike that the eye even of experienced men cannot always detect the difference. This is precisely the case with clay land we farmed for a long period, for although the soil looked all alike, yet some was extremely fertile, whilst in other parts it hardly produced average crops under good management. Much of the poor clay soils in almost every district of the kingdom is unproductive whilst in pasture, chiefly because it was never properly seeded down, but often allowed to run to waste after being exhausted by continuous corn-cropping.

WORK ON THE HOME FARM.

The Work for Horses will be various, in accordance with the state of the weather. In open weather the fallow ploughing will be continued, if frosty the carting of dung, earth, or chalk, as required by the system of management adopted. If the weather should prove fine it is well to continue the threshing of corn and

the storing of the straw, for as the corn is put in ricks now instead of stored in barns, the straw should be put into rick as fast as it comes from the machine. It should also be as carefully thatched as a rick of hay, and cut out in the same way, whether required for use or sale. It is desirable also that the threshing of corn should be done in the winter months when labour is plentiful and not so much required in the fields, the corn itself being sold or stored as may be decided upon, according to price, &c.

Hand Labour.—Men will be employed in the routine labour of the farm, such as filling and spreading dung, earth, &c., trench-digging in the meadows, regulating the flood water in the irrigated meadows, cutting hedges, ditching, banking, &c. Women, too, should be regularly employed, otherwise we cannot expect them to work a few days and be idle by turns, and at the present price of men's labour and boys away at school, women's labour is most important, for much work on the farm must go undone, particularly the light work, or else it must be done by men without turning to profit. Women will now be employed in preparing roots for the cutter and pulper, and also cutting roots (unless done by horse or steam power) for cattle and sheep. Men and women both may also be employed in forking-out couch, docks, &c., in the turnip fields, before feeding-off with sheep, also upon land not yet ploughed for spring corn. We find it always answers a good purpose to fork-out the couch grass, if there is ever so little, because if allowed to remain it increases so much that instead of spending 1s. to remove it by hand labour, it soon costs 20s. in horse labour, besides the delay at seed time.

MANAGEMENT OF HEDGES.

THOSE that have hedges to cut this is the time to have them done. Should any have a young hedge to begin with let it grow as it likes for four or five years, and do not top or buckhead it, but have it laid or, as is termed in Lincolnshire, plashed, and this should be neatly done. The fence or quick is planted in double rows, cut down one row close to the ground, not allowing any of the stools to be more than 2 inches above the ground; the other row will, if the plants are good, require half of them to be cut out, the other half to be laid down and neatly staked, placing a light binder on the top. After plashing do not top or trim any of the growth before the following autumn or winter, and after that trim once a-year and no more, as experience has proved that frequently trimming hedges is quite a mistake. I am acquainted with a district where great pride is taken with the hedges, and these were trimmed twice every summer, and to the astonishment of all these hedges became covered with white moss, and after a few years began to decay and die in patches. These hedges were then allowed to grow for three years, and after that they were plashed and trimmed once a-year only; but the herbage was cut clean from the roots, which is of the greatest advantage to get what is termed a good bottom. In some districts all young hedges are trimmed from the first year they are planted, and where this practice prevails there are scarcely any good hedges to be seen; that is, they all have open bottoms, whereas had they been plashed or laid they would have made as good fences as any in the north.

Those who have young hedges to plant should trench the ground 2 feet deep and plant on the level without any mound or high bank, which is not only unnecessary but disadvantageous to the growth and well-being of the hedge.

Draining.—Those who have any draining to do this is the season for doing it. This work requires some judgment, and should not be commenced hastily and without much consideration. First of all test your ground well by digging out holes in different places and ascertain where the surface is the strongest. Next ascertain the direction in which the water flows, then cut your drain on the angle to catch the water across the flow. I have seen a few drains carefully cut in this way do more good than a greater number of others cut in the same direction or course as the water flows, and the expense saved, has been considerable.—A LINCOLNSHIRE FARMER'S SON.

THE JARDIN D'ACCLIMATION OF PARIS.

LONG after the establishment of our Regent's Park gardens Paris was without any similar place of recreation worthy corresponding with them. In years past we have made peregrinations to that dull, distant, and deplorable place the Jardin des Plantes. Strange is it that any place near Paris can be so dull. We went there in hopes of seeing something interesting in the collection of birds, but vain indeed was our hope, for beyond a flight of Pigeons we never found anything worth looking at. These were certainly remarkable for their great diversity; an original stock of many pure breeds had evidently been allowed to cross and recross till a singularly mottled and particoloured flight resulted. The Jardin d'Acclimation is a far different place, and fully supplies the want. It was a sunny Sunday afternoon in April when we last visited it. Thither all Parisian life seemed flowing; the fashionable classes in smart carriages up the Champs Elysées, the humbler bourgeoisie on those singularly convenient omnibuses by obscure

COLLECTION OF FOUR DIFFERENT VARIETIES.—1, J. Baker. 2, S. Salter. 3, R. Leech. SELLING CLASS.—*Parrot*.—1, J. Newman. 2, S. Salter. *chc*. *Simon*. *Single Bird*.—W. Massey. 2, H. W. Weaving. 3, S. Harding. SPECIAL FLYING CLASS.—1 and Cup, F. W. Benham. 2, W. H. Dunham, jun. 3 and 4, H. Duke, jun.

CAGE BIRDS.—BLACKBIRD OR THRUSH.—1, H. Clift. 2, T. Jenkins. *chc*. J. Symes. GOLDFINCH.—1, S. Cook. 2, Mrs. J. T. Holmes. *chc*. J. Orchard. LOVERIDGE & COWARD, E. Arnold. Goddard. 2, Mrs. W. C. Drummond. *chc*. Mrs. J. T. Holmes. SIX ENGLISH BIRDS.—1, Mrs. J. T. Holmes. 2, S. Cook. 3, Mrs. W. C. Drummond. SELLING CLASS.—1, F. Geary. 2, Lovering & Coward. 3, Mrs. Parsons. *chc*. G. F. Dunn, E. Arnold, Mrs. Parsons.

JUDGES.—Poultry: Messrs. Teebay and Dixon. Pigeons: Mr. P. H. Jones. Cage Birds: Mr. G. Billett.

THE NATIONAL PERISTERONIC SHOW.

REFERRING to my notes I find the next birds to be noticed are the Barbs. After careful inspection of these I have come to the conclusion that the character of the head is much altered from the form of bygone days, being more round, and few if any birds possessing the peculiar angles so sought for by the Barb fancier of only a few years ago. As to size they are much larger birds, and as a sequence coarser, and they seem to have quite lost that neat appearance that a good Barb should possess; while the eye wattle of many was of such a deep crimson as to call forth the remark from many besides myself that it was at least peculiar, looking almost unnatural. Still, as time changes all things, why not the colour of the wattle around a Barb's eye as well as it does the shape and character? Yet there were several very good birds shown, some of Mr. Headley's and Mr. Jones's showing fine breadth of skull and were also well wattled.

The Carriers were in great force, Mr. Headley showing the greatest number; but other good fanciers were well represented with less numbers, but in many cases not less in quality. It struck me that most of the birds lacked what I call finish in the eye wattle, some looking as though it was dragged out to cover a certain space, and lacking that easy regularity of form and points which if well set in complete circles around the eye greatly adds to its beauty. I well remember a bird of this description shown some years ago at Birmingham, when my much-esteemed friend and truly excellent fancier Mr. Cottle was my colleague in judging. It was a great treat to both of us to come across such a bird, and we had it out again and again simply to admire before we could leave it to proceed on our duties. The wattle was so even, the texture so fine and silky, and the colour of the flesh left nothing to be desired. To my mind I have never seen that bird's equal before nor since; but that is one out of twenty-five years' experience in reporting and nineteen years inclusive of judging at Birmingham. It was a prodigy. Many and many a good bird has passed through my hands in that time, but still my memory reverts to that bird. I look on the Carriers as one of the breeds of Pigeons that the shows have really benefited. Take the present for instance; and where a few years back could half the number of such good birds be found? There was scarcely a really bad bird among them. As a whole the sight was most gratifying.

The Almond Tumblers I did not think quite so good as usual, Mr. Jayne's birds being less good in the ground colour. Mr. Merck had a very good bird as regards colour—only some shades too light—being of the pure almond yellow that the old fanciers so greatly admired, and had it only been deeper and richer would have been a typical bird.

As regards the so-called Jacobins, I did not see one true to the name, nearly all being what the Jacobin fanciers would call Ruffs. Some I pointed out to a friend were the exact counterpart of the variety known as the Ruff, and had none of the properties of the Jacobin intact, save their colour and eye. They were very pretty birds I am willing to own; but why call them Jacobins when they lack their properties and are much more nearly allied to the Ruff, which is next to the Capuchin? I suppose next Pouters will be bred without their large windbag, and the excuse will be "it is the fashion." I hope some day to see prizes offered for the true old Jacobin pure and simple, and perhaps that will be ere long, for it is a great pity so very beautiful a variety should be lost. There must be some in Germany, for I had a pair of Blues from there that left little to be desired either in size, form, or colour. In England I do not know where to look for them.

The pens of English Owls were anything but satisfactory. There they were with gullets, but mostly without, though so many have said that they should have them, which I say distinctly they

should not. But in the same pen there they were with and without—with frills and with roses—large coarse-looking birds; and as a friend of mine who is looked on as a most excellent fancier (and he also exhibited Owls then) remarked, not one good Owl head among them. Gone is the curved-down hooked beak. As he justly remarked, they are getting quite Tumbler-headed in comparison to what they were. As far as I could see and learn, the only improvement in them is the price asked, and obtained in many cases. I agree with my friend and fellow fancier, the Owls are not what they should be.

I was much pleased with the Turbits, and I thought Mr. O. E. Cresswell's birds simply beautiful. I have never seen better frilled birds in the whole of my experience. I think they even surpassed the pens that used to be shown by my late friend Mr. Wicking. This is high praise.

The Fantails were well shown. I preferred Mr. Cresswell's to the other pen, being more true to form and less long; but both had good birds, though all were large. The Pouters were a goodly show, the best being those of Capt. Hill. Mr. Jones's Turbitens were interesting and pretty, though I think the name an odd one, but no doubt will answer until a better is found. Mr. Vere Shaw's cage of Toys contained some choice specimens. The one called a Blue Domino had in my opinion the greatest number of properties and was a most excellent bird, though all were to be much admired both for quality and condition.

There is much credit due to the Committee for the way in which the Show was arranged, which as far as I could learn gave general satisfaction, and it was a credit alike to both exhibitors and management. As I have said at the commencement of these notes, one ought to feel thankful there are such shows, where the fancier can go and criticise, study and learn, the present state of usefulness and beauty of his own particular hobby.—HARRISON WEIR.

TONBRIDGE POULTRY SHOW.

THE second annual Exhibition of Poultry, Pigeons, Cats, and Rabbits was held at the New Public Hall on the 16th and 17th inst. We have had on so many occasions to complain of irregularities in the management of shows, that it is now not only a pleasure but an act of duty to give committees credit for their successful exertions. In many shows a considerable improvement has recently taken place, and Tonbridge in management is entitled to stand in the first rank. The cards were placed on the pens with a promptitude that could not be surpassed, and the space at the command of the Committee was utilised to the best advantage.

Dorkings.—First in the Coloured cock and hen class were good birds and well shown, but we thought Mr. Parlett's pen in the class for two hens the pick of the lot. *Spanish* were capital classes. Cock and hen, first a handsome pair; the lobe of the cock was good in quality and shape. Second a nice pen, cock's comb well placed on his head but ugly in shape. The class for hens for quality we thought the best in the Show, but we noticed some birds disgracefully trimmed. It is difficult for judges to draw a line where trimming is recognised, but we do hope they will set their faces against mutilation of this description. *Cochins*, a beautiful pen of Whites and a Buff hen of Mrs. Christie's were the only specimens that call for special notice. *Brahmas*, Dark cock and hen, an excellent lot, Mr. Lingwood winning with his usual form of birds. Hens, with the exception of the winners, were very moderate. Lights, fair classes but not equal to the Dark. *Game*.—Mr. Warde exhibited some very stylish birds, and was deservedly first in both classes. Mr. Maynard was second with a smart bird. He showed a slight indentation in the skull, otherwise he might have turned the tables on the first. *Hamburgs* were fair. *French* above the average that we have seen exhibited lately. In the *Crève* class we could not find a bad pen. *Bantams* were not so numerous as usual. *Ducks* were not superior.

Pigeons surprised us, some of the best birds in the kingdom competing for the prizes. Carriers a grand class. We were pleased to see the Judge giving style and carriage their just recognition, and not making his awards dependant simply on eye and wattle. Pouters and Dragoons were well represented. Two classes of splendid Jacobins followed. In the class for Tumblers some charming specimens were to be found. One class of Homing Antwerps contained thirty-five entries. To go into the merits of a class of birds like this would take considerable time; the Judge made his selections and then highly commended all the birds, and from appearance they deserved it. Owls.—The winner a grand bird, but we did not quite like the shape of his frill. Barbs another excellent class. Here we thought a bird of Mr. Fulton's should have been in the prize list.

The small-bird classes, particularly the Canaries, had some very good birds, but the pepper-fed predominated. In the Cat classes there were two rarities exhibited—namely, two Tortoiseshell-and-white he cats, and both good. The first-prize White long-hair was very large, and the whole Show good for a local one. In Rabbits a very good doe was first with ears 28 inches long by 5½ inches wide, the next was over 21 inches in ear; both were

good in other respects, as were several other Lop-ears. The Silver-Gray had two fine specimens, and the Any other variety class some splendid specimens for size, &c. The first prize went to a Patagonian, the second to a very beautiful Hare Rabbit.

JUDGES.—Poultry: Messrs. Nichols and Leno. Pigeons: Mr. Esquilant. Cats and Rabbits: Mr. Harrison Weir.

DARLINGTON BIRD SHOW.

THE annual Bird Show held in conjunction with the Industrial Exhibition was opened on the 21st inst., and will continue open until Saturday next. There were upwards of three hundred entries—not so many as might have been expected, or as the very liberal schedule issued by the Committee deserved. In the class for Clear Jonque Norwich there was only a solitary representative; in the Jonque Norwich, evenly marked, none. May it be asked, Where were the breeders and exhibitors of Norwich birds? Surely they have not all sold off their best birds! If so, with what fear and trembling did they refrain from coming to the post in response to one of the best schedules ever issued?

The score of Belgian birds exhibited were the best lot we have seen of late, the contest for honours being mainly betwixt Mr. Forth of Pocklington and Mr. Butter of Sunderland. There was a very spirited competition in Class 4 for Glasgow Dons, the first and second-prize birds in particular being well up in their characteristic points. We cannot say much for the Norwich classes, excepting in Class 6, which contained three specimens of fair quality far ahead of another in the same class, a very quiet-looking bird indeed. Class 8, Buff Marked Norwich, with three well-marked birds, each deserving of the honour gained. There were a few good Crested Norwich, the Buffs as usual being the best. The first-prize in Class 14 (Any variety of crest) was a good all-round bird. There were several variety Gold and Silver Lizards exhibited, notably the first Golden bird, which won easily; good first and second Silvers, and a fair first in the Broken-cap Gold, but which was somewhat surpassed by an excellent Broken-cap Silver bird. There were a dozen Cinnamon birds, out of which number seven specimens were good, particularly the first and second Jonques and first and second Buffs. The Yorkshire classes were well filled, and contained many good Clear Yellows and Buffs. In the Evenly-marked class the first and second birds, the former in particular was a pink of perfection for condition and marks. Mule birds were very good. The first prizewinner in Class 27 was a splendid specimen of a Clear Buff Goldfinch and Canary Mule; the second-prize bird, a Jonque, being very close in attendance. The Any variety of Mule class was a choice lot; the first a Mealy bred between a Brown Linnet and Canary, and the second a Jonque bred between the Greenfinch and Canary. The other birds in the class were very attractive. There were several good cages containing four birds, the first prize going to Lizards, the second to Crested Norwich, and third to Yorkshire birds. Cages with pairs of birds were in abundance, the first prize being awarded to a beautiful pair of marked birds apparently of the Norwich and Yorkshire strains. A good pair of Lizards took second place.

Foreign birds were in good condition, a fine Green Parrot in Class 32, and a Pennant Paroquet in Class 33 taking a first, with a beautiful King Parrot second, both birds being in extra good condition.

British birds were well represented with Goldfinches, Bullfinches, Blackbirds, Thrushes, Starlings, Skylarks, and Linnets, and there were also representatives of the Jay and Owl tribes. Many of the prize birds were beautifully plumed.

VARIETIES.

A CORRESPONDENT writes from Buckinghamshire:—"I must say the new year opens with good prospects for the autumn-sown crops. Wheat and oats are looking remarkably well; even wheat that has been sown late after turnips is up and looking strong and healthy. The autumn has been good for the seeding, and a good acreage of autumn corn has been sown this season."

—PRODUCE OF EGGS.—I have only seven hens, three of which have not been laying since September, and five pullets hatched in May, yet from the 6th of November to the 18th of January these have laid 143 eggs, as I find on reference to a book in which they are daily noted down. I may mention that they are fed with oats, whole Indian corn, and Indian meal. The latter is mixed with scraps of all kinds and given to them warm. —HENWIFE, *Stirling*.

—MR. JOSEPH BLUNDELL, in a valuable paper on dairy farming read at the Botley Farmers' Club, observed: In drawing a comparison of the consumption of grass, it is somewhat interesting to know how much more profitable is the conversion of grass into milk instead of beef. Many years ago a great agricultural authority—Sir John Sinclair—arrived at the conviction from practical data that the same quantity of pasture grass which would add 112 lbs. to the weight of an ox would enable a cow to yield 350 gallons of milk. With present prices, beef at 9d. per lb.

and milk at 8d. per gallon, the former would realise £4 4s., and the latter £11 18s. 4d., being a wide margin in favour of milk. In considering this matter we must remember that much of the pasture used for dairy purposes would not feed a bullock fit for the butcher, nor could so many head of cattle be fed per acre in grazing. As for dairy cows, my own calculation is, therefore, that grazing store cattle would yield a profit of no more than 6s. per head per week; whereas a dairy cow's produce in milk would yield 12s. per week during twenty weeks, dating from May 1st. These results, however, may be slightly varied by the qualities of grass and other circumstances.

—AN excellent authority has written as follows on egg-producing food:—If fowls are kept well, but not on too fattening a diet, with plenty of green food, and a sheltered yard, you cannot do more to promote their laying. Highly stimulating food may induce a hen to lay a little earlier, but it is at the expense of health and permanency. We say may, because we incline to the opinion that health and vigour will induce early laying quite as successfully as forcing diet.

—MR. LAW, M.P., in referring to the peasant proprietorship existing in the Channel Islands, stated that the largest estate in the Channel Islands was 100 acres, and the average size of the estates was about 5 acres. There was a small community of peasant proprietors who exhibited a wealth and prosperity not to be found anywhere else. There could be no true family life without that which in its proper sense was a home, and there could not be a home in its truest sense if the owner was not assured in its possession for himself and his family.

—WHY FARM LEASES NEED NO LONGER BE STRINGENT.—In my early days, seventy years ago, farms had to baste themselves, for there were then no manures, bones, or artificial manures; no cotton, linseed, or other cakes; no importation of foreign feeding stuffs, such as maize, &c.; no means of intercommunication by railways, steamships, telegraphs, or penny post; no mangels or kohl-rabi; no farmers' clubs or agricultural shows, no agricultural newspapers, no steam thrashing machines, no steam ploughs, no reaping or mowing machines, and scarcely any agricultural implement makers. But now all this is changed, and British agriculture has become almost a manufacture. These changes have rendered necessary a great increase of tenant capital, but it can hardly be expected to flow in sufficiently or abundantly unless duly protected, and with the newly required freedom of action. No doubt landowners have considered all this, and have perceived the necessity for concurrent changes and improvement in leases and homesteads, with drainage, enlargement of fields, &c., so that the British farmer may be better enabled to sustain the contest with foreign competitors.—J. J. MECHI.

—DR. FELIX SCHNEIDER, who has been trying various experiments for destroying lice on poultry, has communicated the following to a French agricultural journal:—"After trying various remedies for freeing my pigeons and poultry of vermin but without success, the idea struck me to have recourse to a well-known insecticide used by the vine-growers of the south for the destruction of the phylloxera, the sulphide of carbon. The very next day I was agreeably surprised to find that the enemy had left, leaving none but dead and dying behind, and on the following day not a single living insect was to be found, while my birds were sitting quietly on the roof enjoying an unwonted peaceful repose. This lasted for twelve days, till the sulphide of carbon had fully evaporated. Twenty-four hours later a fresh invasion of lice had put in an appearance under the wings of the birds in the warmest portions of the house, where there were no currents of air. I replenished the supply of sulphide, and the next morning only a few of these were remaining. The next morning every trace had disappeared. Since that time I have personally made a great number of further trials with the sulphide with immediate and absolute success. I should recommend the sulphide of carbon to be put in small medicine vials hung about the pigeon house or poultry roost. When it has about three parts evaporated the remainder will have acquired a yellowish tinge, and no longer acts so completely as before, but if it be shaken up afresh it will still suffice to keep the enemy at a distance."

—If you desire cheaper meat, writes Mr. J. Algernon Clarke in the *Daily News*, by all that is reasonable and economical help us to stop the immense and scandalous waste of food which makes meat dear; secure our herds and flocks against calamities which eat up our resources and deter us from multiplying our production; and leave off exposing 45,000,000 home animals to the havoc of imported disease for the sake of having it said that some of the 1,800,000 foreign animals imported in a year may be killed at one end of a railway journey in this country instead of at the other.

—WITH forty-seven millions of arable acres at command, the population of Great Britain and Ireland is largely dependant upon foreign supplies for daily food. The extent of this dependance is not generally understood; but last year Great Britain expended for foreign food no less than £96,879,000. The year before the money paid for similar articles amounted to £87,129,000. So in one year there is an increase of hard cash paid away to foreign

lands of nearly ten millions; or there was within a few hundred thousands of an increased outlay of ten per cent. These startling facts are surely enough to make everyone pause to consider what we are doing at home to allow this outlay to be possible. Free traders have said over and over again that such an expenditure is the best thing that could occur, as the money is scattered abroad in new countries and new markets are created. But it seems to us that if a large share of this ninety-seven millions sterling had been earned by the agricultural labourers and tenant farmers of Great Britain for subsequent distribution by them equal "markets" would have been created at home, and the manufactured articles thus in increased demand at home might have been supplied at a less cost for carriage.—(*Irish Farmers' Gazette*.)

SIZE OF BAR-FRAMED HIVE.

YOUR correspondent "B. & W." referring to my account of experiments which I made with a sixteen-frame wooden hive last summer, tells us that he has constructed a similar one, but thinks that he has not got the correct measurements: $22\frac{1}{2}$ inches is not correct. The inside length should be $22\frac{1}{2}$ inches. For six extra bars he requires six half-inch extra spaces between bars, and $\frac{1}{2}$ inch \times 6 for space occupied by the bars—i.e., 3 inches $+$ $\frac{3}{4}$ inches = $3 + \frac{3}{4} = 3\frac{3}{4}$ extra. To this add $14\frac{1}{2}$ inches and we have a total $22\frac{1}{2}$ inches. I hope that your correspondent will find the working of the hive satisfactory. However, he knows as well as I do that it is not a particular "hive" which gives success, but the system of management carried out by the bee-keeper, providing that he has at his disposal such a hive that the bees and combs in it are at any time easily inspected and manipulated.—P. H. PHILLIPS, *Offley Lodge, near Hitchin*.

OUR LETTER BOX.

FOOD REQUIRED FOR FOWLS (*H. S.*).—What is the nature of their run? Does it afford food of any kind? We say of any kind, because there are two sorts of natural food. One is plainly visible in the shape of herbage or of growing seeds, the other is found by the foraging fowls in odd corners and other places where there is covert for them. This may be easily tested. Let a barrowload of fresh soil be brought from the garden or from a roadside. Let it be examined ever so closely nothing will be perceived. Turn the barrow over and leave a heap, then turn out the fowls. Then will begin a scene which will remind you of an ant-heap. The cock will give his invitation in the customary "cup" or "cook." The hens will respond; they will call the chickens, and all will go to work. The mound becomes flattened and spread out. All are busily at work, and there is not one that has not partially filled its crop. In these particulars the fowls seem to have a microscopic power which enables them to see that which is not visible to the naked eye. Like the drop of water at the Polytechnic, so clear to the unaided sight, but when viewed with help was an animal pandemonium, where every evil passion was let loose, and violence and bloodshed became the rule; so, wherever there is a run with grass and fresh earth there is food for poultry. If your fowls have such a run, then 4 ozs. of good grain, barley for preference, will be plenty of food for each bird. If the run is very bare give 5 ozs. during cold and trying weather, and diminish it in the fine weather in the summer. There must be discretion in the mode of feeding. Corn must be thrown down on a hard surface where it cannot be trodden-in or hidden, otherwise, whatever your allowance may be, you are not sure the birds get it. It is also profitable to give a little at a time in several feeds.

CROSSING FOWLS (*A Subscriber*).—We do not approve your cross. The Spanish are good but not early layers. They moult with difficulty, and they do not sit. The Brahmas are early layers, moult easily, and are good sitters. The cross will not make a better fowl than this latter. As a rule we are not fond of crosses, as we believe pure breeds are better. Nevertheless, if you will cross, we advise Brahma pullets and a Dorking cock. We must, however, tell you it is not the property of any breed to lay in the winter. It is essentially dependant on age and good, judicious, but not over-feeding. Those who will have early eggs must keep pullets to lay them. They must be renewed year after year, for they are only pullets once.

PROFITABLE EGG-PRODUCERS (*H. N.*).—After many years of experience we believe the best egg-producers—i.e., those that lay the greatest weight of food in eggs, are the Dorking, Brahma, Cochins, and Game. They are also all good sitters and mothers. We keep Brahmas and Cochins. We have not been without eggs one day throughout the winter, and the number now increases daily. If in your garden you want vegetables and flowers out of season—those that should come in March, if you want them in December you make your arrangements accordingly. If you trusted to the naturally sown seed it would come in its season. Just so, where other arrangements are not made fowls will not, being left to themselves, lay till February. That is the natural time. But knowing that pullets lay at a certain age, and that at the time when you will want eggs, you must make provision in the spring by saving such as will attain the proper age at the required time. There is then no difficulty in arranging for your eggs during every month of the year. Almost any breed will answer this purpose; but if you seek a breed that will when adult lay in the winter instead of the spring, we must say we know of none such.

PIGEON LAYING FOUR EGGS (*An Old Subscriber*).—It is certainly very unusual for a Pigeon to lay four eggs, and to have also hatched four young birds. We have before now had a bird that laid three, but the last was rough-shelled and imperfect. Are you sure that no other hen laid to yours? For instance, a hen which just before had lost her mate, and then she naturally would be beaten away from the nest, and not be allowed to sit by the cock of the other hen. There is much need of investigating such a case very closely, as it is wholly out of the natural course of things. It would be worth while to shut up the pair by themselves, and take every care against any trick being played. It is also odd that there should be four birds hatched, as a Pigeon can only suitably cover two eggs; and then this is winter, and the very best nurses only succeed in feeding three, and those not well. Has no mischievous boy deceived you?

UNITING SWARMS (*T. Hops*).—By no means touch your hives now. Wait till March or an unusually still warm day in February for the rectification of your fallen combs. Put your box as a super over not under the hive. You may unite the other two hives, but not till much later in the year. It should have been done in the autumn. Smoke and sprinkle the bees with sugar and water in warm weather, then reverse the hives so that the weakest may go up into the strongest hive. Choose a late hour in the afternoon. What you say of the bees coming out on the warm days and not returning home is a bad sign. We should fear they were starved, and, having no food, became too enfeebled to return. If so, you must supply them at once with food in the best way you can. Perhaps the best plan is to make a temporary eke and lay some nice comb full of food flat in it, then gently elevate the hive on the top of the eke, close up the entrance, and shift the hive for the night by your kitchen fire. You can replace it in the morning, and let the bees fly the first fine day.

FEEDING BEES (*J. E.*).—If your bees have eaten all the food you gave them in autumn they should be fed at once; but if they have stores enough to last them a month longer better not feed them till February. By turning-up the hive you may examine the combs and ascertain if feeding is necessary. In February, feeding will do good whether the bees need or not.

BEE DYSENTERY (*Gardener*).—The bees of your second swarm are suffering from an attack of dysentery, which will probably ruin the hive. Give them a little good syrup made of the best lump sugar. The glass cover between the bars and the lid of the hive should be removed—indeed it should not have been placed there at all.

FALLEN COMB (*Phonetic*).—If there is no brood in the comb that has fallen the sooner it is removed the better. You will do no harm to the bees by turning the hive up for examination, and by so acting you may be able to fasten the comb in its old position. Sectional supers may be used on any kind of hives with adapting boards.

REMARKS.

- 16th.—Very bright sunny morning; afternoon cloudy but fine; brilliant sunset and moonlight evening.
17th.—Fine and sunny until late in afternoon, afterwards dull but fair.
18th.—Rather foggy morning, still thicker and dark about 10 A.M., cleared slightly about 3 P.M., but came on foggy again at night.
19th.—Slight fog early, and dull all day.
20th.—Much warmer; damp and dull all day, with drops of rain at intervals; windy.
21st.—Very mild and muggy, overcast but without rain; windy at night and very warm.
22nd.—Gale in early morning, with heavy rain about 2 A.M.; close dull day, fresher after 7 P.M.; windy at night.

The most remarkable feature of the week has been the high temperature of Monday and Tuesday; the latter having a mean temperature of 51.7° , is within one degree of the hottest recorded at Greenwich during the sixty years ending with 1875. The 23rd and 24th of January, 1834, seem to have much resembled the 21st and 22nd inst.—G. J. SYMONS.

COVENT GARDEN MARKET.—JANUARY 23.

We have no alteration to make this week.

From observations taken near London during forty-three years, the average day temperature of the week is 44.6°; and its night temperature 31.5°.

DUKE OF BUCCLEUCH GRAPE.

HERE seems to be considerable diversity of opinion as to the merits of this Grape, and from the various reports which have lately appeared in the horticultural press there can be little doubt that many growers have not succeeded in growing it to that perfection of which it is capable. Being one who has succeeded in growing it in such condition as to cause my employers to order a very considerable extension of its growth and to tell me that Duke of Buccleuch and Muscat of Alexandria are the only two white Grapes worth growing, I think it not more than simple justice to state my experience of it, and how much it is appreciated in the dessert by my employers.

Ever since the Duke was sent out I have never found any difficulty in producing handsome bunches and very large berries of it alike when grown on its own roots and grafted on Black Hamburgh and on Muscat of Alexandria; but I find that the heat which is necessary to do justice to the Muscat is too much for the Duke, inasmuch as the latter ripens so long before the former that the heat necessary in the Muscat house causes the Duke to shrivel prematurely unless used when just ripe; therefore I have confined it to plants on its own roots and to grafts in the Black Hamburgh house, where some six varieties of Grapes requiring the same heat are cultivated. Under such treatment the Duke has always produced plenty and to spare of bunches for a crop, but more freely on the young wood than on the spurs until the spurs are three years old when on its own roots. On the Hamburgh stock it fruits more freely on the spurs than when on its own roots. I have ripened it to an amber colour the first week in September, and sent it to table fresh and plump in November, and find that it is most highly relished. Indeed, having a Vine of Buckland Sweetwater in the same house I had instructions to let the cook have its fruit when he called for white Grapes.

The treatment the Duke receives has not been in any way special except that in thinning it the operation is not performed till the berries are the size of peas, for if it has a fault with me it is that it does not set very freely, but always sufficiently to produce uniformly well-shaped bunches without artificial impregnation. As I have said, the result of the above experience is that preparations are being made to plant a houseful of it.

Considering the precautions taken to prove this Grape before it was sent out, I think it scarcely fair to the raiser of it for those who have failed to grow the Duke satisfactorily to speak of it and its raiser as they have spoken. It will be remembered by many that before it was certificated by the Royal Horticultural Society Mr. Barron of Chiswick was sent from London to inspect the crop of it at Tweed Vineyard and, if my memory serves me aright, to Drumlanrig also, and that his report of what he saw there led to its being certificated. Not only so, but I believe it was sent by hundreds of pounds weight to Covent Garden previously to this inspection—at all events before it was sent

out—and these realised more per pound than any mid-summer white, or indeed black, Grapes.

I have no desire to champion this Grape nor to say that anyone has mismanaged it, but I do say from my own experience of it that it is a grand Grape, noble in appearance, and, excepting the Muscats and Frontignans, having no equal in quality as a white Grape. I think it scarcely fair to write of it as some have recently written of it, that its being sent out was the "greatest cheat," which means, of course, that its raiser is a cheat. Has any other Grape been put to the test of Covent Garden and inspected by a competent agent at two different gardens before they were certificated?

If it gets the same chance as well-cultivated Black Hamburghs it is my opinion that the Duke of Buccleuch Grape will succeed. There are circumstances under which, of course, it will not succeed, and they are these: It will not fruit freely nor set well if planted and trained thickly; nor will it come to perfection under a system of steaming, damping, and syringing, now abandoned by all who produce good Black Hamburghs and good clean Grapes of any other variety.—COLUMBUS.

ROSE NOTES DURING 1877.

"WILTSHIRE RECTOR," "D., Deal," Mr. Luckhurst, and others have all addressed a new year's greeting to the readers of the Journal, and it would not be like old times if I, who am a humble representative of the Rose interest, should not offer my congratulations. The year that has lately passed away will ever be reckoned as one of the most memorable in Rose annals, for during that year the National Rose Society held its first exhibition. This though a financial failure, was in everything else a great success, and, what is more, the financial failure was not allowed for one moment to prejudice its future career. Noble generosity from some of the great cultivators of the Rose (both professional and amateur) at once made matters straight, and we were told to go on and prosper, which we intend to do. An independent show, which was one of our great aims, we found to be impracticable, and so we drew in our horns and resolves to throw our protecting aegis over some kindred society, and this year we unite with the good folks at Sydenham in June, and with the cute men of the north country at Manchester in July. We think, and we are not afraid to say, that such a show will be held at Sydenham as has not been yet seen in even that great crystal home of the Rose. We mean not to draw in our horns because we are taken in tow by a great Company, but to sail our ship alongside our great consort with honour to ourselves and benefit to her.

The Show at St. James's Hall will, I think, long linger in the minds of all true rosarians. It was a real show. It was like classical music, the highest and purest form of art. Rosa alone without any adventitious aid held her court. Musica even kept away; no string band discoursed sweet strains from the orchestra, for that was given up to the sweetest of the members of Flora's court, and the eyes and noses and not the ears were appealed to; and yet in

another sense; even the ears drank in their music also. "How are you, Wyld Savage? Have not seen you since we met two years ago at Hereford. Glorious sight, old fellow. Splendid show;" and every kind of congratulatory greeting met one on every side. Mr. Jowitt and Mr. Baker's struggle will not soon be forgotten. Neck to neck they ran for a long time, and it was only a matter of a few small blooms in the latter's stand which secured the cup to the former. But the glorious contest will be waged again at Sydenham, and these and other giants will put in an appearance such as will arouse the admiration of all who love the Rose.

And now what shall we say of that much-contested point the financial success of Rose shows? I suppose, as a rule, we must say that Rose shows cannot pay—or rather do not answer. They exist almost by the skin of their teeth, and many have to resort to expedients which are hardly fair, and would not certainly be employed if the financial strain could be relaxed. Such, for example, is the entrance fee of a guinea or half a guinea demanded at all but metropolitan shows. Surely the exhibitor who is put to the great expense of bringing his exhibits often hundreds of miles should not be called upon to subscribe as well to the show, and yet without these subscriptions no country society could exist.

What other expedients are there to make Rose shows pay? Some men answer, "Give smaller prizes." I cannot assent to this, not on my own account, but, sinking all personalities, on account of my brethren in general. Anyone who has shown Roses for any time knows the great cost of the exhibitions to him. He has to take a long journey, and pay for his gardener as well as himself. My friend Mr. Baker had three assistants at St. James's Hall, and though he arrived before the doors were open he could only just get his Roses staged in time. Then you have to stay two nights and sometimes three in town, or have to leave your man and hurry home to prepare for the next show. The prizes really are most inadequate to the expense. The only thing I can suggest is to reduce the number of classes, but then that will also reduce the size of the show. The whole matter is a most difficult problem, and no solution at present offered is satisfactory. During the coming season it would be very interesting if the secretaries of the various societies were to give an account in the *Rose Journal* of their receipts and expenditure.

The great nurserymen really cannot be asked to accept smaller prizes; their expenses are really very large. They take one or two men, whose time at that season of the year is most valuable; they and their foremen are both absent from home; they have to show so many blooms, and their boxes are so numerous, that they have to pay large sums to the railways for extra weight, and their other expenses are doubtless great; so their prizes cannot be cut down. Added to this, they are the most generous-hearted men I have ever met. The freedom from jealousy, the bond of brotherhood so warmly felt and evinced by them all, makes Rose-showing a perfect treat, as (if for nothing else) a place where charity in the fullest sense of the word is so largely evinced. At least these are my sentiments, but then I am only a—WYLD SAVAGE.

VEGETABLE CULTURE.

CHAPTER V.—BROCCOLI.

THERE is so little perceptible difference between Cauliflower and Broccoli, and as the one gives a continuation to the other of the same vegetable, this chapter may very appropriately follow the one on the Cauliflower. The Broccoli grows wild on the shores of the Mediterranean. Like other vegetables for which there is a great demand the original form has been improved immensely, and the varieties now in cultivation far exceed in number any other of the Brassica family. Numbers of varieties said to be new are annually introduced, but most of them prove to be synonyms. But there are exceptions to this rule, and the greatest that has been made for many years past is to be found in Veitch's new Self-protecting Autumn Broccoli, which in my opinion is a very valuable variety. It is called an "autumn" Broccoli, but in reality it is both an autumn and winter variety, as we cut it from the beginning of November until the end of January. Its heads are large, compact, well protected, and high flavoured.

Referring to the last chapter, and beginning with the end of the Cauliflowers, Veitch's Autumn Giant will bring the supply up to the beginning of November. For carrying on the supply during November and December at the very least, Veitch's new Self-protecting may be grown. Walcheren and

Grange's Autumn White Cape are frequently said to be good autumn Broccoli, but they are as tender as summer Cauliflowers, and should never be depended on. For cutting during January no better variety can be grown than Snow's Superb Winter White, and Backhouse's Winter White is very little inferior to it. Osborn's Winter White is another useful kind for the same period.

For cutting throughout March and April we have found none so suitable as Cooling's Matchless, Frogmore Protecting, and Leamington. To succeed these in May and June the old Wilcove has few superiors; but Melville's Superior Late White, Cattell's Eclipse, Carter's Summer, Sutton's Late Queen, and Webb's Champion have all the requisite qualities to give a supply until the early Cauliflowers come in.

It is sometimes thought that as Broccoli come in one after another they must be sown in succession, but this is not the case. Those heading in April and May have to be sown at the same time as those which head in November. A supply may be secured from then for the next six or seven months from two sowings. The first sowing should be made during the middle or the end of March, and the second about the end of April or beginning of May. A little seed of all sorts should be sown at both of these times. Unless in exceptionally late springs it is not necessary to sow the seed under glass, unless it is in a cold frame where the lights can be drawn on when necessary. We have always found Broccoli do well in a border exposed to the sun but sheltered from cutting winds. Strong manure need not be used to raise the young plants. A quantity of old hotbed manure when leaves were chiefly used in its formation is excellent stuff to dig into the ground on which the seed beds are to be formed. It should be turned into the soil a few weeks before sowing the seed. It is most convenient to sow the seed in beds about 3½ or 4 feet wide. In a small border only 8 or 10 feet wide two sorts may be sown on each bed. When the beds are long a little space about a foot wide should be left between each sort. Good seed should never be sown thickly. Place the name of each variety on a label, and mark underneath the date of sowing. This applies to all kitchen garden seeds. In cold soils as soon as the seed is sown it should be covered over with about half an inch of old soil sifted fine from the potting shed. Where this cannot be had common garden soil mixed with its own bulk of leaf soil will do as well. Where the soil in which the seed is sown is good a little may be thrown out of the alley and sprinkled over the seed, then rake the bed lightly over, and finish it off by giving it a gentle beat all over with the back of the spade. This should be done when the ground is in good working order. It is better to wait a week or ten days than to sow the seed shortly after rain. The second sowing must be similarly conducted; but when the soil is very dry on the surface it should be well watered before sowing the seed, which must be covered over immediately. When the weather is dry at the time the young plants are coming through they should be frequently watered. This must be attended to in light shallow soils.

As Broccoli is frequently planted after early crops of some other kind, it is generally necessary to give the young plants more room than they have in the seed bed before finally planting them out. As soon as the plants are about 4 inches high the largest of them may be drawn out and dibbled about 4 inches apart into any rich piece of ground. Plantations may be made from both sowings, as the plants are ready and the ground vacant, during May, June, and July, supposing Broccoli to be succeeding early Potatoes, Peas, Turnips, or even late Broccoli. As soon as the ground has been cleared of these a good coating of strong farmyard manure should be spread over the ground and dug-in deeply. If the plants are ready for planting the surface of the ground should be broken fine with the spade as digging goes on, and the plants should be put in before the soil dries. When the plants are not ready at the time of digging the surface should be left rough, and just before planting break it fine with a four or five-pronged fork. As it is often hot dry weather in June and July it is a great advantage when the plants can be planted either just before or immediately after a shower. Independent of this, each plant should be lifted with a trowel and planted with a good ball. When planted properly the plants sustain little check. Dry weather has its advantages for planting, and so has wet. Excepting just a shower at planting time there is less trouble with the plants when dry weather follows until they have started into growth. It is next to impossible to prevent snails from eating numbers of the plants, and they have a persistent

way of taking them immediately after they are planted. Dry weather checks their movements, wet aids them. Dusting with fresh lime, placing a ring of sharp ashes round each plant, and gathering the snails frequently with the hand, must be diligently attended to whenever a plant is lost. When very dry weather follows the planting and the plants make no progress a good watering at the root assists them greatly. Where many are grown good soil and plenty of manure should be more depended on for making good plants than watering them with liquid manure.

From 2 feet to 30 inches every way is a suitable distance for planting. The ground on which all Broccoli is planted should be well exposed, as plants grown in a sheltered place do not endure a severe winter well. When the plants are 10 inches or a foot high the Dutch hoe should be run deeply through the soil amongst them, and then a little soil should be drawn to their stems. In another fortnight or three weeks both hoeings should be repeated. This will complete the earthing-up, and should any weeds appear between the rows afterwards the Dutch hoe must be employed to keep them down.

In autumn the plants must always be kept free from dead leaves. The heads should be cut before they can be fully seen through the leaves. Frost injures them, and on its appearance a number of the leaves should be broken and turned over all heads approaching maturity. During very severe weather or in the time of snow a little dry fern or straw should be thrown over each plant, especially those forming and just about forming heads. When a lot of them are ready to cut at the same time a number of them should be lifted when dry and set in a shed where a mat or a little straw or fern can be thrown over them. Very severe weather frequently kills many Broccoli plants; but in localities where this is known to occur all the plants that are to produce heads throughout the winter and spring should be lifted with good balls and planted in a trench with their heads facing the north. The leaves protect the centre better when lying like this than when the plants are upright. This transplanting is generally done in October or the beginning of November. Sometimes a spadeful of soil is taken from the north side of each plant, and the plant laid and fixed on its side without lifting it entirely. The little fly which causes so many of the Cauliflowers to go "blind" acts the same on the Broccoli; but the soot-and-lime remedy is as fatal to it on the one as the other.—A KITCHEN GARDENER.

KEEPING GRAPES—DEW.

AFTER a tolerably lengthy experience of gardeners I have arrived at the conclusion that they, like the representatives of most, or perhaps all other crafts, have their "little weakness"—a weakness that I doubtless share, but of course without admitting it, perhaps even without knowing it. Our peculiar idiosyncrasy is in disclaiming that Nature specially favours us when we achieve a success. We do not readily admit that we possess any natural advantages of site or soil or water when we succeed rather better than our neighbours; yet, nevertheless, the advantages often exist although their precise nature may not always be easy to define.

Mr. Thomson possesses natural advantages for growing Grapes at Drumlanrig, and he sets a worthy example by making the best of them. Nature has provided him with good soil, splendid drainage, and a liberal water supply, which are prime essentials in Vine culture. Those are his advantages. His disadvantages are a deficiency of sun, still he manages with surprising success to produce good Grapes, and with little trouble prevents them from decaying. According to his own showing they may be said to keep naturally. Wherein or in what manner, then, does Nature aid him? I have suggested by affording him a screen of the best of all materials—clouds—for arresting the radiation of heat and thus preserving an equable temperature, which prevents the deposition of moisture on the berries, which is, as I have proved by direct experiment, a fertile source of decay. Although Mr. Thomson has adjudged my logic right and premises wrong, I shall yet remain firmly convinced that I have pointed out the real cause of the immunity from decay of the Drumlanrig Grapes until a more cogent reason is forthcoming.

I remember reading an article written, I think, by Mr. Thomson, setting forth the extraordinary amount of cloud incident to the vale of Drumlanrig. The fact was placed very strongly, for if I remember rightly the number of cloudy days in the year were stated, and these were very remarkable.

Now it amounts to a certainty that when clouds prevail to such an unusual extent that the temperature is more equable than when clouds and sunshine alternate extremely, and that the deposition of dew is in the same extent governed. It is a law of Nature which we are bound to accept. Yet when Mr. Thomson lays stress on the remarkable absence of sun, it is not to be inferred that it never shines or that there are not occasional starlight nights. Neither is it surprising that when sunny days do occur that the danger of scorching is unusually great; nor, on the other hand, that when clear nights occur the dews are unusually heavy. We have no right to expect any other results than those. The character of the district remains the same, and that character is remarkable for its high cloud average.

An occasional and extreme variation of temperature during any one day does not afford correct evidence of the true nature of the district. A difference of 57° in sixteen hours is an extreme range, but how many times has that occurred in a week, or I might add in a year? I have an entry in my meteorological diary of 2 inches of rain falling in two hours, and 4.95 in the day of twenty-four hours; yet that does not prove the district a wet one, for when the returns from several hundreds of rainfall stations were published, that referred to was amongst the ten lowest, and was indeed very near the bottom of these. So much for the value of a solitary instance of extreme figures of temperature or rainfall in determining the average character of a given locality.

During some seasons Grapes keep about as well on the Vines as when the stems bearing the bunches are placed in bottles of water and arranged in the Grape room. That is when the seasons are more than usually exempt from, not occasionally extreme, but frequent and sudden changes of temperature. I have been in the habit of trying both plans for several years, and have observed particularly that the more equable has been the temperature the better have the Grapes kept on the Vines. I have gone further than that, and have proved that by affixing a blind to a roof of a division of a vinery, and drawing it over the glass during clear cold nights, and often in the middle of very sunny days, that the Grapes in that division kept better than those that had no screen to arrest radiation, and consequently to promote an equable temperature. When Grapes are bottled and placed in a room having a temperature ranging between 40° and 45° their surfaces are in a condition to condense a minimum quantity of moisture, hence the absence of decay. In a vinery exposed to constant and sudden changes of weather the temperature is necessarily more variable, and the greater and more frequent are the changes the greater is the extent of the decay of Grapes. That such is the fact I have proved by many years of careful observation in my own district, and I suspect it is the same in other localities.

I readily admit that occasional extreme changes of temperature exist at Drumlanrig, but sunny days and clear nights are the exception rather than the rule. Mr. Thomson has written strongly on the unusual prevalence of cloud in his district, and just in proportion as clouds prevail, in the same proportion is radiation arrested, an equable temperature promoted, and the decay of Grapes prevented.—A NORTHERN GARDENER.

AURICULAS—THE WOOLLY APHIS.

I WISH to give a warning word to the lovers of Auriculas.

Last year about this time I called attention to an insidious enemy in the shape of a subterranean wholly aphis, and some correspondence in your columns appeared upon its treatment which called forth a letter from the Rev. F. D. Horner, the prince of Auricula growers, the most successful exhibitor, and most authoritative of writers on the subject. I need not repeat his advice, I can only say I followed it, even to burning the frame on which my collection of plants had stood. Yet the aphis is now re-appearing, and in some cases with great vigour. It is exactly the time when it came last year, and I advise Auricula growers to turn out their pots and examine the drainage, the roots where they touch the pot side, and the neck of their plants, where the telltale white woolly substance will at once reveal the presence of the enemy. If he is there soft soap or Gishurst him; he may stand one application, but repeat it and disturbance is more than he can endure, while to allow him to remain is to insure the destruction of your plant's rootlets.

Another word. The late lamented Mr. Andrew Murray in describing Aphis Auriculae in the pages of the "Florist" acknowledges his very close resemblance to the aphis found on

the roots of the Jerusalem Artichoke, and I must say the points of divergence are so trivial as to make me think it possible the species are identical, and that the differences found may be caused by altered diet and circumstances. It would therefore be safest—until at all events authorities can definitely uphold the theory of the two species—that we should keep our Jerusalem Artichokes at a respectable distance from our Auriculas.—JOHN T. D. LLEWELYN.

NOTES ON THE APPLE.

I AM much interested in Mr. Killick's excellent remarks on orchard Apples, which, taken in connection with what has been written by a "A NORTHERN GARDENER" and others, prove that the Apple is at length asserting that position which it is justly entitled to by its manifold uses and importance.

I must apologise to some late writer on the Apple by having inadvertently spoken disparagingly of Lord Suffield Apple. I think I must have been misunderstood, as the little I said on it was that in this neighbourhood public opinion was about equally divided on the merits of Stone's Apple, or, as Mr. Killick calls it, Loddington Seedling, and Lord Suffield for supplying the early market; but as a gentleman living near here had gained the first prize at a metropolitan exhibition for a collection of kitchen Apples not long before Christmas, amongst which Stone's Apple was one of the varieties shown, I experienced a doubt whether at the same time a dish of Lord Suffield could have been found worthy of such a distinction. This was all that I recollected of having written other than in the most laudatory terms of this useful variety.

There are one or two other Apples that I wish to draw attention to, and if possible elicit further information. Mr. Killick incidentally mentions a variety very extensively grown around here, which usually passes under the appellation of Graham's, or, in a more lengthened phraseology, Graham's Pyle Russet, a late-keeping Apple of good appearance and size, and an excellent bearer. The tree attains the largest size of any variety grown, and its bloom when out is amongst the largest and boldest of any that are met with. I believe the variety has several synonyms, and I think is sometimes called Dusand and at times Gorham Gray's, but I do not think a name by which I have heard it called is at all the just one—Herefordshire Pearmain, as that fruit in some other counties differs widely from the one grown in Kent as Graham's. The latter, however, had a bad reputation at one time in the London market as a kitchen fruit, not cooking well, but this was evidently owing to its having been sent to market too early, as it is one of the best keeping Apples I know of, equalling the French Crab in the latter respect, but it is for its good bearing qualities and the large size the tree attains that I beg particularly to call attention to it. It is not unusual to meet with trees which have produced forty bushels of fruit and upwards—indeed, I am not sure if nearly double that quantity has not been affirmed to have been gathered from an old Graham. In point of size the old Golden Knob approaches it nearest—i.e., in size of tree, but they do not resemble each other, the latter being more semi-hemispherical in outline, whereas the former is a more upright grower.

The Northern Greening is also a favourite orchard Apple, and generally a good bearer, and last year, when so many sorts failed, there were some fair crops of this variety in the neighbourhood. I am also pleased to see that Mr. Pearson calls attention to another old favourite of mine, but little known in Kent I believe—Barton Freebearer; it was once grown largely in Lancashire, but I have not seen it for many years. Keswick Codlin is, of course, to be met with everywhere, and is perhaps the very earliest grown for market purposes, it being often gathered long before any others—in fact, the current remark is that a Keswick Codlin, like a Potato, is old enough as soon as it is large enough, and I believe at a further advanced state it carries better than the Cellini and some others. I am not sure if several more may not be added to the list of soft-skinned bad-travelling Apples. The Cellini is seemingly a descendant of the old Nonsuch, and is not the Emperor Alexander another doubtful traveller, pretty as it looks on the tree? The complaints of Duchess of Oldenburgh are very correct in this respect, whilst amongst old varieties fallen into neglect that can hardly be blamed for the fault given above is Manks Codlin, which used to carry well, but I believe is often met with in a speckled condition, and consequently unsaleable. I believe this is often called the Pitcher Apple in Kent; at least I could not distinguish their difference. I will now ask the question,

Is Normanton Wonder the same as Wellington? I confess not being acquainted with the first-named. Dumelow's Seedling we all know is the same as Wellington, and I can only add my testimony to what has been already said of the value of this variety as an orchard fruit. As a dessert fruit late in the season it will be some time ere the old Golden Knob be driven out of the market. It being a hardy and in general a good bearer, and the tree attaining to a larger size than most other table Apples with which I am acquainted, Perhaps one of the best kinds of recent introduction as a substitute for it is Court Pendu Plat, or, as it is often locally called, "Corpender," which has become a great favourite of late years in this neighbourhood.

I can confirm what Mr. Killick says about Lord Suffield as being too large to withstand the high winds that usually occur before the fruit is ready for gathering. This is also a complaint laid against other large Apples, many of which would be otherwise great favourites, as Gloria Mundi, Tower of Glamis, Warner's King, Bedfordshire Foundling, and many others, which accounts for the paucity of large varieties of Apples being found in ordinary orchards composed of standard trees.

Some varieties of Apples keep better during certain years than they do in others. A friend of mine had some Keswick Codlins of the growth of 1876 in very good preservation in March of the following year, and other varieties of that year's growth kept also very well; while during other years ordinary good keepers were almost all gone by the time above mentioned. Amongst old varieties still grown in this neighbourhood for their late-keeping qualities the old Norfolk Beefing is still often met with, and when grown on healthy young trees the fruit is not at all speckled or disfigured by disease; but the one having the reputation of being the latest keeper is French Crab, which I believe has many aliases, but is usually known hereabouts by the above name. The new Hawthornden has all but quite ousted the old one, which has become more diseased than varieties probably ten times its age. I find, however, I have said enough on this head for the time being, but am exceedingly glad to see the subject has been taken up so well by others.—J. ROBSON.

A FOSSIL FUNGUS.

IN the *Journal of Horticulture* for December 27th last (p. 486) an excellent paper was published on the Potato disease, and reference was made by your correspondent to a fungus in a fossil condition very similar with the fungus of the Potato disease, and named by me *Peronosporites antiquarius*.

The fossil fungus is of the highest possible interest; firstly, from its great antiquity, for it dates back so far into the past that it is simply impossible to compute its age in years; secondly, on account of the fungus being in all its parts exactly the same in size, structure and habit with similar fungi of to-day. This fungus preserved in a fossil collection, and belonging to the Palaeozoic age, came under my notice in the following manner:—My friend, Mr. William Carruthers, F.R.S., keeper of the Botanical Department of the British Museum, first observed this or a similar parasite some years ago in a slide (belonging to the Museum collection) prepared to show the nature of the scalariform axis of a *Lepidodendron* from the coal measures. By the permission of Mr. Carruthers I have examined this original slide, which contains spawn or mycelium and cells containing reproductive matter named oogonia; and I believe the fungus to be the same with the one now under description, although far less perfect. The newer and more perfect slides were lent to Mr. Carruthers a year ago by Mr. J. T. Young, F.G.S. Shortly after this time Mr. Carruthers placed the section with two others in my hands for careful examination. The slides had previously been seen when in the British Museum by Dr. Rostafinski, and this gentleman expressed his belief that the parasite in the vascular bundles belonged to the genus *Pythium* (a genus confused a good deal with the genus *Peronospora* by some recent writers on the Potato disease) on account of certain "swellings" occurring on the mycelium. I am not disposed to place much value on "swellings," but I place great value on the presence of distinct septa in the mycelium and zoospores within the oogonia. Dr. Rostafinski probably did not notice the jointed mycelium, or he would not have referred the fungus to *Pythium*, and I have authority for stating that he overlooked the zoospores. Mr. Carruthers in a few words (illustrated by a very small and sketchy woodcut) referred to this fungus in his printed presidential address to the Geologists' Association on Nov. 3rd, 1873.

So far as I am aware no perfect fruit has hitherto been detected upon any fossil mycelium, and no description, except that of a *Mucor*, also from the coal measures, has before the present instance been published of any well-defined fungus belonging to the Palæozoic series of rocks. It is, however, possible that a paper in the "Annals and Magazine of Natural History," 4th series, vol. iv., 1869, p. 221, and tab. ix. and x., describes and illustrates a fungus of a somewhat similar nature with my *Peronosporites*. The paper in question is communicated by Messrs. Albany Hancock, F.L.S., and Thos. Atthey, and purports to describe five species of "*Archagaricon*" from the Cramlington black shale. The authors state that the fossil fungus has been found at Newsham and in other localities. They, however, describe "lenticular swellings" with a "reticulated surface," a state of things I have never seen, and spore-like bodies within the mycelium, which is clearly an error of observation. The authors also refer their plant to *Sclerotium stipitatum*, and they say they can find no "important difference" to distinguish this latter plant from their coal fungi. Of course *Sclerotium* is not a fungus at all, but a mass of condensed my-

celium, and the Cramlington plants do not resemble *Sclerotia*. Plate x. might pass for *Peronosporites* drawn by a bad draughtsman unacquainted with fungi; but as the descriptions are imperfect and do not give critical dimensions, no one can say what Messrs. Hancock and Atthey really had in view.

Beginning with the mycelium of *Peronosporites*, a close examination of this shows that it is furnished with numerous joints and septa. If, therefore, any reliance is to be placed upon the modern distinguishing characters of the now living species of *Peronospora* and *Pythium*, as furnished by a septate or non-septate mycelium, then the fossil parasite belongs to *Peronospora*, and cannot belong to *Pythium* or any of the *Saprolegniæ*. The oogonia do not agree with *Cystopus*. Within many of the fossil oogonia the differentiation of the protoplasm into zoospores is clearly seen; but if any doubt could exist as to the exact nature of this differentiation, then other oogonia (or zoosporangia) on the same slide show the contained zoospores with a clearness not to be exceeded by any living specimen of the present time.

In the accompanying illustration is shown some of the

Fig. 14.—A FOSSIL FUNGUS (*PERONOSPORITES ANTIQUARIUS*, W. G. S.).

- A, A'.—The Fossil Fungus showing the jointed spawn threads and the cells (oogonia) containing the reproductive mass; at B one cell is seen still attached to its thread, and another is seen just detached at C.
D, E.—Oogonia showing the zoospores *in situ*.
F.—An oogonium from the fungus of the Potato disease, showing similarity of size in both oogonium and zoospores.
All enlarged 400 diameters.

jointed spawn threads (A A') and two of the cells containing the reproductive material. It will be seen that one cell (B) is still attached to its thread, whilst the other cell (C) is just broken off from its late point of attachment. At D and E are illustrated cells in which zoospores are to be seen actually *in situ*; at E the cell wall is seen to be somewhat broken, a very common state of things in similar bodies of the present day when mature and seen under the microscope. For comparison a zoospore-bearing cell belonging to the fungus of the Potato disease is illustrated at F to show that the ancient and modern bodies are positively identical, even the minute zoospores being exactly the same in size and form with those of *Peronospora infestans* when measured to the ten-thousandth of an inch. The average number of zoospores in each oogonium is also the same—viz., about seven or eight. The aerial condition of the fungus has not yet been observed. It may be objected that a primordial plant could not have led a parasitic life, for if parasitical then this fact would point to some pre-existing plant. But it must be remembered that some of the now existing species of *Peronospora* have a great tendency to put on terrestrial habits, and several species (including the fungus of the Potato disease) will grow and perfect their fruit upon humus alone. *Botrytis terrestris*, Pers., can always perfect itself upon the ground, and normally leads a non-parasitic life, whilst many of the *Mucedines* grow freely in cellars on damp walls or in any moist place. It is quite possible that many of these moulds were at first terrestrial, and that they ultimately took to a parasitic life as more favourable to their existence, and the occasional terrestrial habit of the modern

species may perhaps not unreasonably be looked upon as a reversion to the habits of an anterior state of existence.

After my remarks on *Peronosporites* had been made public P. Martin Duncan contributed a very valuable article to "Science Gossip," in which he demurred to my *Peronosporites* being "perhaps the oldest fungus on record;" but as I never used these or any such words I need make no reply further than by stating the expression to be none of mine. Mr. Duncan then gives several valuable references to where accounts are given of the *Saprolegniæ* and other *Algæ* being found in formations more ancient than the Palæozoic rocks. The information is doubtless valuable, but my description refers to a fungus as I estimate a fungus, and not to an *Alga*.

In *Peronosporites antiquarius* we then probably have a representative of one of the simple primordial plants of the great family of fungi. The *Peronosporæ* are closely allied to the *Algæ*—so closely, indeed, that De Bary says the species of the former may with reason be compared with the species of one group of the latter named the *Saprolegniæ*. Some botanists place the *Saprolegniæ* amongst the *Algæ*, whilst others consider them to be true fungi, and there is no reason why they should not be an intermediate class of plants. If *Peronospora* should, therefore, ever be considered an *Alga* (and its extremely close relationship is doubted by none), we have in *Peronosporites antiquarius* a plant which from its extreme antiquity would seem to lend some favour to the views of Sachs and other evolutionists. These observers place the lower *Algæ* amongst the primeval plants from which fungi and all other cellular *Cryptogams* have branched; and the finding of *Algæ* in

the Devonian and the upper and lower Silurian series of rocks, as enumerated by Mr. Duncan, is a further confirmation of the possible correctness of these views. Neither is this position invalidated by the presence of the more highly organised vascular Cryptogams living at the same period of time with the primordial Alga or Fungus; for although the vegetable kingdom may have now reached a generally higher development throughout the world than in the Palæozoic age, yet this fact does not make the supposition unreasonable that the lowest forms of life may even now be under the process of creation, or under the process of being evolved from still lower forms of life beyond the reach of our microscopes, but that life can spring from no-life I consider unreasonable. The lower forms of life of to-day are possibly destined for development into diverse forms for future ages; but this is no reason why the well-spring itself should stop at its source, whatever that source may be. It is clear that the law which called the Peronosporites into existence countless ages ago is in force now, and that this law produces the same results now as then. Whatever changes may have taken place in the external aspects of natural objects the fact clearly remains, that the great cause which first brought these objects into being has for immeasurable ages remained perfectly unchanged.

The readers of the *Journal of Horticulture* will remember that when my discovery of the resting spores of the Potato fungus was first made public a most improper criticism of my work was published by Professor A. de Bary of Strasbourg. My determination of the fossil fungus now under description has met with a similar criticism, not indeed from Professor De Bary himself, but from the hands of one of his pupils, Mr. George Murray, now of the British Museum. This gentleman writing to the "Academy" of November 17th last rashly stated my drawing with the oospores *in situ* to be "purely imaginary," as he could testify "from having seen the specimen." Now of course it depends a good deal upon who the gentleman is who "sees a specimen," and what sort of eyes he uses in seeing it. A rustic might look for a long time through a good telescope without seeing Jupiter's moons, but an astronomer who knows what to look for and expect sees them at once. As soon as I saw the oogonia in the fossil attached and free and exactly agreeing in size and habit with oogonia now existing I at once looked for the zoospores, and clearly saw them, not in one specimen only, but in many. It was only reasonable to imagine from the first that they would be there. When one sees a petal, what is more natural than to expect the presence of an anther or a stigma? My critic then went on to refer to the "Darwinian theory" and the "Struggle for Existence" (in inverted commas), subjects I never even mentioned in my paper. When I moderately replied to Mr. Murray he turned round (like Figaro) and said the oospore as figured by me, "if a correct representation, had become fossilised in the act of emitting zoospores, a process always swift" &c. Your readers will be surprised to hear that I never thought of, suggested, or wrote anything to this effect. Mr. Murray placed his own interpretation upon my drawing, and then proceeded to demolish his own (as I believe erroneous) construction. I wrote to this effect to the "Academy," but my letter possibly miscarried on its way to the office;—at any rate it was not published.

I need only say in conclusion that the "specimen" has been publicly exhibited by me under the microscope at Hereford, where some of the keenest English and French microscopists were present. It has been exhibited at the Linnæan Society and before a well-attended meeting of the Scientific Committee of the Royal Horticultural Society. At none of these meetings has any doubt whatever been thrown on the true nature of the fossil zoospores, so that Mr. Murray may be said to stand alone in his printed opinion of my "purely imaginary" representation of these bodies.—WORTHINGTON G. SMITH.

ANTHURIUM ANDREANUM.

THIS is a new species, said to be of the greatest magnificence, and enthusiasts say it will place A. Scherzerianum entirely in the shade. This is to happen not only from the superiority of its gorgeous cordate-ovate orange-red spathe, which is 3 or 4 inches across, but also from the finer habit of the plant. It is only in habit and form that we think it can be said to supersede A. Scherzerianum; in colour, if we may judge from the figure, it is not superior. It is really a very distinct plant, and therefore scarcely comparable. Its leaves are ovate-lanceolate and cordate, so that it may appear better

furnished, to use a technical expression. The spadix we should mention is yellow, having the peculiar feature of a white band about the middle, which covers a space equal to about one-third of the length. Horticulturists will no doubt await with considerable anxiety the appearance of this plant in commerce. It is in the hands of M. Linden, by whom it was named after M. André, who found it in New Grenada and transmitted it to Europe. A figure is given by M. Linden in his "Illustr. Horticoles," t. 221. We do not think it will displace A. Scherzerianum, but rather that cultivators will grow both.—R. I. L.

JUDGING ROSES.

"I HAVE been much pleased to read of Roses and Rose-showing in the *Journal*. It will certainly be a great drawback to small growers when they know that they must purchase such a large quantity of Roses before they can compete with any probability of success. I question, again, whether many growers would be so anxious to score a success as to pick all the buds from "a good Rose plant" but two, as is done by "WYLD SAVAGE," or to cut "the whole of a plant away" to obtain one bloom of Marquise de Mortemart, as was done by Mr. Jowitt.

Those who go in for exhibiting must make some sacrifices; but it does seem that the queen of flowers requires greater sacrifices to be made to her than any other flower I am acquainted with. The man who intends to exhibit and goes in to win must plant Briars and Manetti stocks. As some guide to those intending to plant I must say that the seedling Briar gives the best blooms in our light soil. I planted two hundred yearlings, each plant as large as a knitting needle, some three or four years ago; they made exceedingly strong shoots the first season, and were budded in July and August following the January in which they were planted. The next season I could have cut several stands of exhibition blooms from them.

I would have liked if "D., Deal," could have stated what he considered the best way to judge Roses. He objects to every conceivable way of doing it, but does not say how it ought to be done. He says at the outset that "we must dismiss from our minds the elaborate proposals which have been made as to taking the number of points in each flower." Now I believe that in a close contest there is no other way of arriving at a just decision. "D." supposes what never happened when he writes of judging thirty or forty stands of twenty-four Roses by points. Let us suppose forty stands are staged in one class to compete for, say, four prizes, I am certain that three good judges would walk quickly down the row and in five minutes they would reject all but eight or nine stands; they would then more closely scrutinise the nine, and would without going into points reduce the number to five or six. Now comes the tug of war. A, B, and C are so nearly alike that the best judges are puzzled what to do. There is only one way out of the difficulty, and that is to give a certain number of points to each flower, and the highest number gains the prize. If there is an easier way out of the difficulty than this I as a frequent judge in close contests would be glad to know of it. It will never do either to take into account a mass of difficulties as to the distance an exhibitor has to carry his flowers or the means at his command to produce them. A judge has only to do with the Roses as he sees them on the table; and to take into consideration the fact that A's soil is light on hot gravel, while B has good loam on the chalk, or that C has brought his flowers only twenty miles, while D has carried them through across country two hundred miles, is too much to expect from him.—J. DOUGLAS.

BEAR with me in this last attempt to put my proposals in a working form. Four sets of judges, non-exhibitors, having been selected and told off for the amateurs' side, four good old experienced hands and eight younger ones, making three to a set; one of the young hands in each set is only required to know a bad from a good bloom, or what is an ordinary exhibition flower and what is not. He is furnished with a packet of small black strips of card of the same size as labels. He is allowed five minutes' start of the other two judges, runs with a sharp eye over each row of blooms and excludes, disqualifies, or blackballs all the inferior non-exhibition flowers by laying the black card on such Roses. In the fifty-guinea-cup class his work should be very light. Now the other two judges follow, one with a packet of two-point cards, and the other old experienced hand with a small packet of three-points. All the blooms now before them are supposed to merit one

point as exhibition flowers without a card. Now the remarkably good blooms amongst these according to the rules and opinions of the judges have a two-point card placed against them; after this a few of only the grandest high-centred treble X flowers have the three-points card superadded to their other honours. The young blackball judge now comes behind the other two, counts up the points in each entry, writes the number on each, records it in his book, and returns with the other two to reconsider the verdict in cases of tying or disqualifying, and the work is done; and on this plan it should be to the satisfaction of even the losing exhibitor, who may be consoled by knowing his number of points and how near he was to winning, and so his disappointment if taken in a right spirit will bring him nearer perfection another year.—H. C., *Torquay*.

VINE BORDERS.

If my memory serves me right "A NORTHERN GARDENER" relies a good deal on the chemical effects of the soil used. So would I if I knew as much about it as a certain well-known gentleman who lives at Rothamstead; but after trying many times to persuade myself that I know something, I have reluctantly come to the conclusion that the little I do know of the subject is not worth taking into account compared with what gardeners know about the mechanical properties of composts, and somehow, provided the mechanical properties are right, good fruit is always forthcoming under good management. I, however, am persuaded of one chemical fact—that ashes of any sort (and coal ashes most of all), counteract to a great extent the stimulating effects of ammonia. And again bearing in mind that wood ashes are mostly potash, I am persuaded that it is unreasonable to use one-fifth or even one-sixth of this material in a fruit border; and that is what it comes to now after "A KITCHEN GARDENER'S" further explanation. As I said in a former paper, I prefer charcoal both for its mechanical and chemical properties; and although I do not know for a proved fact, yet I have a suspicion that most charcoal, especially when the dust used for covering the fire is mixed with it, contains quite a sufficiency of potash for the good of the Vine or any other plant.

I have a strong objection to making fruit borders very rich at first. Make them right in texture and sufficiently rich to promote average growth, and it is a very easy matter to add stimulants at any time.

Loam is now generally used quite fresh by all the best growers when they can get it; if it is fibry the decaying fibre will afford almost sufficient stimulant for the good of the plants during the first year or two, and if a small addition can be added about every two years afterwards there will be very little else wanted. All, however, cannot procure good turfy loam, and they must make shift with the best substitute at command. I consider the most important point in making a fruit border is to have it right in texture, and if possible it is advisable to make it lasting. Now charcoal is comparatively everlasting, and so are wood ashes; but vegetable manure is not, and after it is decayed I consider it does more harm than good. When manure is required I would use the strongest kind, so that the least possible bulk would suffice. Fibry turf does not remain fibry for ever, but if a border is made up piecemeal the roots of a Vine will to a great extent take the place of the decayed fibre in keeping the soil from becoming too close together, and the loss of manurial properties in the piece of border already decayed can be made good by the use of top-dressing and liquid manure. There is no doubt in my mind that night soil is the best of all stimulants for Vines, but it must be used with caution; it is no use to apply it in large quantities to weakly plants with few roots any more than it would be to feed a dying man with turtle soup.

Almost any kind of soil in an emergency may be used for the principal staple of a Vine border, and there is no doubt that common garden soil would produce better Grapes than half the fancy mixtures which are used in the present day. I have had to use some queer-looking stuff for Vines myself at times, but by mixing powdered clay when the staple was too light, burned clay when it was too heavy, and night soil when it was too poor, success has often followed where failure might have been expected.

I can of course tell of failures, but it will scarcely do for professional gardeners to indulge in such a luxury, unless their audience is exclusively well up in horticultural difficulties. I will, however, tell of one which was not of my own

making, and which may serve as a caution at the present time.

Less than twenty years ago I had, under the proprietor, the charge of the most popular Vine-growing establishment in Britain. When I entered on the scene hundreds of splendid Vines in pots such as I had not seen before in quantity met my gaze. It was in January or February and they were leafless, but appeared perfect in every respect, and many of them were sold for such a price as ordinary Vine-growers do not dream of asking. As spring approached they started growing strongly, and promised to produce splendid fruit; but the promise was all, and they came out of the pots simply like knobbed sticks, without the shadow of a root. They must have had good roots and plenty of them during the previous season or they could not have produced such canes. Many were the complaints received from people who had bought them, and although the best that could possibly be done under the circumstances was done to make amends, still the lost season could not be restored nor the disappointment prevented. The cause of the failure was calcined oyster shells, very good in their way no doubt, but they were used in excess. I do not know whether wood ashes in excess would produce a similar result, and I do not mean to try them.

Another partial failure was brought about by having the compost too rich in vegetable matter. The roots seemed to absorb more than the plants could elaborate or evaporate. The pith was black, and so were the bases of many of the leaf-stalks with the portion of the stem against them. This was cured by root-pruning and keeping the growth back till late in the season, when the sun became powerful and evaporation consequently very great.

These and many other warnings have made me decide on making fruit borders rather just a little too poor than a little too rich. The former is easily remedied, to remedy the latter is often impossible.—WILLIAM TAYLOR.

NOTES AND GLEANINGS.

At the great Summer Show and Meetings of the ROYAL HORTICULTURAL SOCIETY this year "an amateur," anxious to encourage the cultivation of Amaryllises, offers prizes to be competed for at the Society's Meetings to be held at South Kensington on March 5th and April 2nd. Mr. William Bull announces that the sixth annual series of prizes, amounting to £260, will be distributed in silver cups for 1878. There are prizes also offered by Messrs. James Carter & Co. to be competed for by gentlemen's gardeners and amateurs only. F. Gallop, seedsman and florist, Brighton, introducer of Miles's new Hybrid Spiral Mignonette, will offer through the Royal Horticultural Society, at their great Summer Show in May next, three money prizes to be paid on the first day of the Show, for twelve plants of his new Mignonette, to be grown in 6-inch pots. Prizes are offered by Messrs. Hooper & Co., September 17th, for dish of twelve fruits of Acme Tomato; November 19th, for the best dishes of nine tubers each of the following six new varieties of Potatoes—viz., McKinlay's Pride, Covent Garden Perfection, Grampian, Triumph, Trophy, Burbank's Seedling. Prizes offered by Messrs. Sutton & Sons, November 19th, for twelve Sutton's Improved Reading Onions, for twelve tubers Sutton's Magnum Bonum Potatoes, and for a collection of vegetables, in twelve distinct kinds. The exhibition of the Pelargonium Society for 1878 will be held, by arrangement with the Council, in the Royal Horticultural Gardens, South Kensington, on June 18th, in conjunction with the Rose show of the Royal Horticultural Society.

— ROBERT MARNOCK, Esq., has at the express wish of the Committee consented to preside at the thirty-fifth anniversary festival of the Gardeners' Royal Benevolent Society, to be held in the ensuing summer.

— A VERY practical improvement is in progress in the ROYAL HORTICULTURAL SOCIETY'S GARDENS AT CHISWICK. The long half span-roofed corridor-like structure which has hitherto been occupied with an useless collection of Vines on one side, and an equally unremunerative collection of cordon Peaches on the other, is being converted into a vinery which in a few years cannot fail being profitable. The varieties selected for planting the structure, which is upwards of 200 feet long, are the Black Alicante and Gros Colman. As a good border is being made and the house is now efficiently heated a satisfactory house of Grapes may be confidently relied on. The cordon Peaches which have been removed from the house have been planted against vacant walls in the garden. In a very few

years the value of the Grapes will defray the cost of the alterations, and a profitless house will be rendered profitable.

A MEETING of the Executive Committee of the NATIONAL ROSE SOCIETY was held at the Horticultural Club on Tuesday last, J. T. Jowitt, Esq., of The Old Weir, Hereford, in the chair, when the schedules for the shows at the Crystal Palace and Manchester were arranged, subject to further revision. Among the special prizes announced were a cup or piece of plate given by Rose-growers for sale as the chief prize in the class for twenty-four Roses, single trusses, amateurs; a cup by Edward Mawley, Esq., for the best six Roses, amateurs; a five-guinea cup by W. Robinson, Esq., for Roses sent out prior to 1850; and a cup by amateur exhibitors for the best thirty-six Roses, nurserymen.

AT the Annual Meeting of the Committee of the HORTICULTURAL CLUB, held at the Club House, Arundel Street, on Tuesday last, the following gentlemen were elected members of the Committee in lieu of three retiring members:—Colonel Peechell, the Rev. Geo. Henslow, and Mr. A. Wheeler; and the following gentlemen were elected members of the Club:—Edward Mawley, Addiscombe, Croydon; G. F. Morris, Leytonstone; and W. Prothero, jun., Leytonstone.

THE TRIALS AT CHISWICK this year comprise flowers, fruit, and vegetables; the flowers by a very large collection of Irises, the fruit by about 130 varieties of Strawberries in pots to test their relative merits for forcing, and the vegetables by Cabbages, of which a great number of reputed varieties are planted. The result of these trials will be both interesting and instructive.

MR. WITHERSPOON writes as follows from Chester-le-Street on the FRUIT PROSPECTS IN THE NORTH.—“It is already very clear that Pear blossom will be very sparse in this district. We shall soon, I am afraid, find to our regret that we have not done with last year's sunless summer yet. On taking a casual glance plenty of what might be taken for fruit buds are simply leaf buds. Beurré d'Amanlis is all right, while Beurré Superfin is barren, so is Durondeau and several others; while Williams' Bon Chrétien and Louise Bonne of Jersey are fairly set. Amongst Apples Lord Suffield is all right, as are Victoria and Transparent Gage Plums. The fine autumn did much in the way of ripening the wood, but I suspect an earlier sun was necessary for the perfecting the blossom buds.”

AS evidence of the MILDNESS OF THE SEASON we have received from Herefordshire a Gloire de Dijon Rose picked from a north aspect on the 22nd inst., the thermometer having recently been 62° in the shade.

A NEW ROCKERY is just about being completed at Chiswick, and forms an agreeable approach to the great viverny. It is composed chiefly of large rough stones and clinkers, and, common as those materials are, they have been arranged in a manner that renders the rugged pile attractive. The rockery has been formed by the garden operatives acting under the guidance of the superintendent, and due provision has been made for the well-doing of the collections of Alpine plants that are now being planted. The different genera are being grouped together as much as possible in aspects best suited to them. Such low-growing plants as Saxifragas, Primulas, Sedums, &c., will be seen to much better advantage on the rockery than in the level border of the garden. Already the collection of rock plants is extensive and choice. This rockery, which was so greatly required and has cost so little, will be a permanent source of interest in the gardens. A few Conifers and Yuccas are planted on the upper portions of the mounds. Already the effect is very good, and of course will improve yearly as the stones lose their “newness” and the plants increase in size and beauty.

MR. RICHARD NISBET, writing to us from Aswarby Park, Lincolnshire, states that he caught a fine specimen of the BRIMSTONE BUTTERFLY (*Gonepteryx Rhamni*) on the 21st inst., having all appearance of being newly hatched, being perfect in every respect. This is generally the first of the butterfly tribe to announce the coming summer. Mr. Nisbet has frequently caught them in February, but never so early as the above date; its favourite months being March and April. A second brood appears in August. The caterpillar feeds on the Buckthorn and berry-bearing Alder. This pretty insect is found as far north as Newcastle, rarely found in Scotland.

THE general unproductiveness, or perhaps unsoundness, of the English Potato crop of last year has had the natural

result of increasing the importation of FOREIGN POTATOES, the declared value of which during the last twelve months increased to £2,346,593 from £1,742,285 in 1876.

THE successful cultivation of PEARS ON THE CORDON SYSTEM at Holme Lacy, Hereford, which has recently been noticed, is confirmed by the weights of fruit of the following varieties:—Glou Morceau weighed 13½ ozs.; Beurré Bosc, 12½ ozs.; Beurré Superfin, 14 ozs.; Beurré Diel, 15 ozs.; Easter Beurré, 16 ozs.; Triomphe de Jodoigne, 14 ozs.; Duchesse d'Hiver, 18½ ozs.; Doyenné d'Alençon, 13½ ozs.; Zéphirin Grégoire, 11½ ozs.; Maréchal de Cour, 14 ozs.; Bergamotte Esperen, 11½ ozs.; Joséphine de Malines, 11 ozs.; and Van Mons, 15 ozs.

A CORRESPONDENT writing to us on the MILDNESS OF THE SEASON IN THE ISLE OF WIGHT, states that Geraniums, Calceolarias, Fuchsias, Stocks, and other summer-blooming plants are still flowering in his garden. Only 2° or 3° of frost have been registered, and only such very tender plants as Heliotropes have succumbed to the coldness of the weather.

THE German botanist, Regel, has discovered in the Himalayas a variety of WILD ONION, which he regards as the original source of our ordinary garden Onion. It is called *Allium cepa sylvestre*.

WE have received from Mr. Thomas Sheasby, The Gardens, Hare Hill, Macclesfield, some very fresh blooms of CHEYRANTHEMUMS. The blooms are not quite so large as they would have been in December, still they are more valuable now than they would have been at that time. Mr. Sheasby thinks it a great point to choose free-blooming varieties for late work. There are four varieties—viz., St. Michael, Jules de Largrègue, Mrs. Forsyth, and Golden Cedo Nulli. Those varieties in the neighbourhood of London faded some weeks ago.

HINTS ON GROWING VEGETABLES.—No. 2.

ROTATION OF CROPS.

JANUARY is pre-eminently a month of rest in gardening matters, and now, if ever, we should be able to make our plans for the coming year before busy April with its more active employments is upon us. Let us in the dull wet days and long evenings read up some of those interesting articles in last year's Journal, which perhaps we could not do more than glance at in the summer, and looking back at our garden book for the past year to see where we have failed, compare the two together and make notes for the coming year to provide against a like mishap.

And here let me strongly urge all who have not yet done so to keep a note-book. It need not be an elaborate one; a simple large shilling copy book with a stiff cover, which we can rule into columns, will answer capitally. The first column for the name of the crop and the variety we are growing; the second for the date of sowing; then, in the case of the Brassica tribe, Celery, Cucumbers, and such-like, let us note when we begin planting out, next the date we begin to gather, and again when we take up the crop. We must have a column, too, for the quantity of seed sown and of the produce obtained, for the circumstances under which the crop was planted, or the manures used; and lastly a column headed “Remarks,” to note what the cook said about us. A page should be reserved for special notes, such as the general character of the weather, the date of any permanent improvements, of planting fruit trees or housing the soil, for all these, though it may appear trifling to note them now, will prove useful “sometime and somewhere.” No one who has not tried this plan can imagine what a help it is towards preparing the next year's work. It reminds us when to sow; that this crop was too late or that too early planted, the year before; that one crop did well shaded, another was improved by using a different manure. “Work for the Week” in the current Journal is very good, and I should do badly without the record; but the work in my garden for the corresponding week of last year, if not so interesting, should prove still more useful to me in warnings and successes.

Another help which I even more strongly recommend to all who wish to make the most of their garden is to draw a plan of it each year. Take the trouble, once for all, to go round some fine day in early autumn and measure your quarters, and much simpler and easier you will find the work if these are square or oblong. From this measurement make a small plan with ruler and foot-measure, say one-fifth of an inch to the yard, and mark down according to scale the space and position of every crop. A series of such plans for previous years will

simplify that most important part of good gardening, the proper rotation of crops.

Now, if it be not already done, is the time to make all the arrangements for next spring, to draw a plan after the pattern of last year's, tentative indeed and liable to be affected by weather, but to be followed if possible during the coming season. Let us see where the various crops were placed last year and the year before. If possible let two, and certainly one year, intervene before repeating the same class of vegetables on the same plot. Of course I am aware that owing to the limited extent of most warm borders rotation cannot be as fully practised in that precious part of the garden as is desirable; but even there it should be followed as much as possible, and the early Potatoes, Peas, and Carrots should succeed each other in a three-years course. Some will point to crops of Potatoes grown in cottagers' gardens on the same ground year after year as an argument against rotation, but in most of such cases the crops gradually deteriorate, and practical experience is against it. The nature of the soil, too, so chemists tell us, is opposed to the practice, for the food of plants is chiefly derived from four elementary substances—carbon, nitrogen, oxygen, and hydrogen. The first they obtain partly from the soil, but principally from the carbonic acid in the atmosphere; hydrogen from the rain and dew which falls on the ground; oxygen and nitrogen from resolving ammonia, the product of decomposing animal and vegetable substances, into these two elements. But besides these gases they require also solid substances, and these they imbibe in a state of solution through their roots; such, for example, as potash, lime, phosphates, sulphates, and silicates. Whether the staple be clay, chalk, or sand, we shall find that in all soils the three are present in greater or less proportions, together with many of the phosphates and acids mentioned above. But these are, so to speak, under lock and key, and require that the soil or decomposed rock (for such it is) should be brought under the influence of rain, wind, and sun before they are dissolved and their riches become available for plant life.

Each kind of plant requires one or more of the salts thus held in solution in greater proportion than the rest. Cabbages, for example, require sulphur largely; cereals require both potash and phosphate of magnesia to perfect their seed. So that by continually growing the same crop on the same plot you gradually exhaust the soil of the available supply of the salt it feeds on, and each crop is worse than its predecessor; whereas careful rotation avoids the evil by giving time for the land exhausted of one set of salts to unlock a further supply by exposure to rain and air, and to receive a fresh importation from the manure applied, and at the same time enables you to do what is most important in kitchen gardens where the heaviest and most continual cropping is required, I mean to avoid fallows and to obtain a crop from another set of salts, and grow Carrots instead of Cauliflowers. Mechanically, too, as well as chemically, you can obtain greater production by rotation; for, suppose Cabbages to have been grown in succession on one plot, by sowing Carrots or other tap roots you get down to a fresh stratum, and a good crop is the result where failure had been the rule. Therefore, to apply theory to practice, let beds be interchanged, roots taking the place of Cabbages, Cabbages of Peas.

A root crop should always, if possible, follow one of the Brassica tribe, as the ground having been highly manured for the first crop will be sufficiently rich for the Carrots without requiring fresh manure, which would cause fingers-and-toes and such-like evils. Let Beet and Parsnips be sown where the Celery trenches were, so that they may have a deep rich soil. Pea rows should be arranged 2 or 3 yards apart and have Dwarf Kidney Beans or Turnips grown between them, where they will do far better in the shade than if exposed. Their positions should be reversed next year that each may come on fresh ground, and a plot should be chosen which has not lately been occupied by the Brassica tribe, so that that class may succeed the early Peas; autumn Cabbages should also follow the Onions. Be careful to keep a shady spot vacant for Lettuces and Radishes in the hot dog days, as their crispness then will entirely depend upon it. Celery we generally like to travel round the garden year by year, visiting all the poorer parts, as no crop is more enriching.

Whenever you require to have land well cleaned in preparation for a permanent crop, such as Asparagus or Strawberries (for I do not find the beds fail in two years as so many complain), plant it with Potatoes. They leave the soil friable and clean and free from slugs, which are generally too plentiful

where Cabbages have stood. Certain crops may be an exception to the migratory rule on account of the difficulty of eradicating them, such I mean as Jerusalem Artichokes and Horseradish.—A YORKSHIRE AMATEUR.

HOME-GROWN TUBEROSES.

"M. D." has pointed out that my note on the above subject was not sufficiently clear in the matter of removing the offsets. I will try to make my meaning plain.

The Tuberose shortly after flowering generally dies quite back, leaving nothing visible above ground excepting the top of the bulb. This period should not be hastened by removing the flower stem or withholding water while there are healthy leaves on it, but it should be allowed to die back naturally, and water should not be altogether withheld, even when there is no visible growth. I pot them at this time without disturbing the roots or any part of the plant and place them in a little warmth. They soon commence growing by forming several little bulbs on and near the top of the old one. If all were left of course they would grow weakly; one only is left, and it rapidly enlarges, having the roots of the old bulb to supply it; the rest are picked off with the finger and thumb, and may be potted and grown in the same way as little Amaryllises. I have succeeded best so far with the bulb which remains on the top of the old one. Probably the young bulbs would take two years to grow them to a flowering size, but I have kept no memoranda on this point.—WM. TAYLOR.

THE FIG AND ITS BLOSSOM.

A LITTLE more than a year ago Mr. William Taylor wrote as follows about Figs:—

"Did you ever see a Fig blossom?" asked a gentleman well learned in theological, archaeological, and most other logical matters. 'Oh, yes,' I replied, 'thousands.' As he was evidently interested in the subject and failed to find the Fig blossom himself, I supplied him with specimens and such scanty information as I was in possession of. He said he had looked in vain in Miller's 'Gardeners' Dictionary' and various other works for particulars and explanations on the subject. I hinted that it might not be understood in Miller's time. 'It was understood long before Miller's time,' said he, 'for the subject is mentioned in the Bible, and some opponents of the sacred book say that the prophet was wrong, as the Fig does not blossom at all; but,' continued he, 'it seems the prophet was right.'

"I have never gone very deeply into the subject, although it is intensely interesting; but to those of your readers who would like to explore for themselves and discover the hidden beauties of the Fig, I will give a few hints which may serve to put them on the right track. I do not know the number of blossoms an average-sized Fig tree bears to within a few thousands, but if anyone will take the trouble to count the number of seeds a ripe Fig contains he will arrive at a tolerably correct idea of the quantity of blossoms necessary to produce a perfect fruit, and the multiplication table will furnish the rest.

"When the fruit is about the size of a small bean cut one of the small fruit lengthwise through the centre, and the blossoms yet unexpanded may be seen very clearly by hundreds, each one mounted on a separate peduncle of considerable length. Well, if these are the blossoms how is fertilisation to take place where not a breath of air can reach? Examine the end of the fruit farthest from the stalk and a hollow will be seen, but at present it is securely covered by small imbricated leaf-like organs, which protect the tender parts till such time as they become perfectly formed, when the door is opened and air is freely admitted to the centre of the fruit. This, I believe, is for the purpose of fertilisation, which takes place when the fruit is grown perhaps to a third of its size. The young organs are then extremely tender; and if, from the weather being unfavourable or the organs themselves being imperfect, fertilisation does not take place, the fruit grows to a certain size, when it, as well as the perfect fruits, cease to swell perceptibly for a time (this, in the case of the perfect fruits, is when they are forming the seeds), and then, instead of starting afresh, turns yellow and falls off.

"The structure of the Fig at the time the blossom is coming to perfection is exceedingly beautiful, even when viewed through a common magnifying glass. A microscope would probably reveal beauties which I do not dream of."

Mr. Taylor was perfectly right in supposing that the microscope reveals much beauty in the structure of the Fig. The flowers are not only numerous but are singularly and chastely beautiful, as may be seen by the accompanying figures.

To the ordinary observer there is little in common between the Fig and the Nettle, yet both belong to the same family—Urticaceæ, and it may be incidentally mentioned that the Hemp, the Hop, the Mulberry, and the deadly Upas Tree are included in the same family—a singular association judging by the general appearance of the plants and their varied properties, yet on a closer examination the essential characters of their flowers are the same.

The Fig is one of the most important as well of the oldest of fruits. Its antiquity is proved from the fact that it is the first of all fruits mentioned in the Bible, in those passages relating to the creation and fall of man. Indeed the Fig tree is often mentioned, both in the Old and New Testament, in a manner to induce us to conclude that Figs formed a principal part of the food of the Syrian nation. When Abigail went to

meet David, to appease him for the affront given by Nabal her husband, she took with her, amongst other provisions, a present of two hundred cakes of Figs.

The fruit was much admired by the Romans, who brought it from the eastern countries they conquered, and had so increased the varieties in Italy by the commencement of the Christian era, that Pliny has furnished us with a description of twenty-nine sorts that were familiar to him. He says, "Figs are restorative, and the best food that can be taken by those who are brought low by long sickness and are on the recovery. They increase the strength of young people, preserve the elderly in better health, and make them look younger and with fewer wrinkles. They are so nutritive as to cause corpulency and strength: for this cause professed wrestlers and champions were in times past fed with Figs." This naturalist mentions the African Figs as being admired; but says, "It is not long since they began to grow Figs in Africa."

The "Hortus Kewensis" informs us that the Fig tree was planted in this country in 1548. Gerard says, in 1597, that

A. Section of a Fig showing the flowers on its inner surface.

B. Female flower of the Fig greatly magnified. *Pet*, petals, which are membranous, transparent, spirally arranged, the upper one, *sy*, being transformed into a stigma-like organ, and may be mistaken for the style which terminates the fruit. *sy*, style; *st*, stigma; *pp*, the membranous transparent pericarp; *ov*, the ovule.

C. The male flower. *pet*, petals; *sm*, the stamens.

D. The ripe seed. *h*, the hilum.

"the fruit of the Fig tree never cometh to maturity with us except the tree be planted under a hot wall." Parkinson also, in 1629, says that "if you plant it not against a brick wall it will not ripen so kindly;" but much must depend on the situation of the country. The same author says in his "Theatrum Botanicum," 1640, "the blew Figge is no doubt of the same operation with the white to all purposes, but the fruit cometh most to maturity with us, and is eaten with great pleasure with salt and pepper."

We make use of the term "fruit," because it is that by which it is best known; but what we call the fruit of the Fig is in reality not the fruit but the enlarged receptacle bearing the real fruit on its inner surface, the real fruit being those innumerable small seeds found on the inside of the Fig. In the East a practice has been followed from time immemorial of increasing the productions of the Fig by what is called "caprification," and it is maintained still. It consists in hanging branches of the wild Fig on those of the cultivated variety; the fruit of the wild plant contain a great number of eggs of an insect called *Cynips pascens*, the larvæ of which, as soon as they are hatched, crawl over the cultivated tree, pierce the fruit, or rather the receptacle, and, passing over the flowers in its interior, convey the pollen from the male to the female flowers, and thus hasten and secure fecundation.

The puncturing of Figs is still performed in those coun-

tries where they are largely grown, for as recently as 1871 a letter from a Naples correspondent appeared in this Journal, stating that "When the Fig has swollen to nearly its full size they take a pointed stick, like a toothpick, dip it in olive oil, and prick the Fig in the eye. This operation is performed on every fruit. Some say they are better flavoured without this operation, but I approve of it, for the unassisted Figs ripen later and become insipid from the rain that then falls."

"Seedlings of the edible Fig," says Mr. Burbidge in his book on the improvement and propagation of cultivated plants, "vary very much in size, flavour, form, and colour; and the numerous forms—upwards of a hundred—now grown in this country have been raised in French, Spanish, or Italian gardens. Doubtless some are merely cultural varieties, and any systematic course of intercrossing is next to impossible, unless, indeed, the fruit can be partially severed—i.e., slit open when the open orifice indicates the perfection of the flowers—and the foreign pollen introduced, after which the fruit might be held together by an elastic band until the margins united again; or it might be possible to insert the point of a fine brush or feather, moistened with honey or nectar and charged with pollen. The variety of fruits obtained when seeds of imported Figs are sown seems to point to hybridisation having previously been effected at some time or other, unless, indeed,

we can ascribe this seminal variation to a long course of cultivation."

SPARMANNIA AFRICANA.

WHY is it that we so seldom meet with or see mention made of this plant? I do not find it in any catalogue or work on

plants with the exception of the "Cottage Gardener's Dictionary." In this useful work it is described as being "a fine old evergreen greenhouse shrub. Cuttings of young shoots in April; loam and a little peat" (the soil recommended). "Winter temperature 38° to 48°. Nat. ord., Lindenblooms."

A fine old shrub it undoubtedly is, and when grown for winter work I know of nothing more useful and showy. Its

Fig. 16.—SPARMANNIA AFRICANA.

only drawback is its comparative uselessness for cutting for vases, &c., as when cut the flowers close in a few hours. For the decoration of conservatories, &c., it is extremely useful, it being not only evergreen but perpetual-flowering. Fine bushes (and this we find much the best shape in which to grow it) can be had in 12-inch pots, and we have in a small tub a plant fully 6 feet in diameter and 9 feet high literally one mass of

flowers. The Sparmannia flowers but little in a young state unless extra sturdy growth is obtained, nor will it be very attractive planted and crowded as I have seen it among a lot of conservatory plants. It will flower when so treated, but seldom till the shoots are too long to be tolerated.

Cuttings with heels attached, taken from the ripened wood, strike readily in the spring and can soon be grown into large

plants. Avoid crowding; pinch back and pot on till the end of June or early in July. A good head being obtained, discontinue pinching and potting, and turn out into an open and sunny spot. The temperature of a greenhouse is the most suitable during May and June.

Old plants when no longer wanted in bloom, which with us is at the end of March, are ripened by gradually withholding water, are cut back to within a few eyes of the old wood, and placed in a gentle heat till they break; they are then shaken out of the old soil and repotted, employing about the same sized pot or tub as they were formerly in. This is rather severe work, as the ball is one mass of roots, but when placed in heat they soon recover from the effects of their rough treatment. The soil used is composed principally of turfy loam with an addition of a little peat, leaf soil, sand, and broken crocks. When re-established they are gradually hardened off, and in June are placed in a sunny position outdoors. Early in September they are taken into their blooming quarters and commence flowering immediately. From that time an occasional dose of weak liquid manure is administered. They flower freely in a greenhouse temperature 38° to 48°, but 48° to 58° is far the best, the blooms being finer and of a purer white; the foliage has also a better colour for the extra heat.

The flowers are produced in great profusion in trusses of about twenty-four buds, which keep up a long succession of bloom. The individual flowers measure 2½ inches in diameter. The calyx consists of four sepals, which are narrow, and white in colour. The petals of the corolla are white with a slight circle of maroon at the base, are also four in number, but are longer and broader than the sepals between which they are disposed. From the base of the ovary and pistil a number of maroon-coloured stamens, the anthers of which are heavily laden with golden pollen, fringed with a ray of curiously shaped golden threads, spring in four prominent groups opposite the sepals. The whole forms an extremely pretty flower.

Next season I hope to be able to try the *Sparmannia* in the subtropical garden.—W. IGGULDEN.

[The engraving is from sprays sent by Mr. Iggulden; they were extremely well grown, one of the trusses having forty flowers and unopened buds.—EDS.]

PARAFFIN STOVE VERSUS FLUES.

DURING the last two winters I abandoned flues and hot-water pipes in a small greenhouse 12 feet by 10 and substituted a paraffin stove with great success. I wintered *Azaleas*, *Myrtles*, *Cytisuses*, *Amaryllises*, *Geraniums*, bedding-out plants, delicate Ferns, &c. I can raise the temperature 10° in an hour, and my stove, a duplex Silber, burns for twenty hours without refilling or trimming.

I have great difficulty here in procuring stable manure for frames or pits, and my note is to ask if any of your subscribers have ever heated their frames with paraffin lamps. If they will answer in a greenhouse, one would argue that on a lesser scale they would do well and be a great boon to small gardeners. The expense of a fire and pipes for one frame is not to be thought of, and as I do not want to run the risk of losing all my plants in my solitary frame with two lights 8 by 6, I should like to have the experience of others to guide me.—E. H.

RAINFALL IN 1877.

YOUR correspondent who, writing from Morpeth, calls a rainfall of 45 inches a downpour, "disastrous alike to both field and garden produce," will probably be surprised to see that the fall in his neighbourhood is exceeded at sixteen out of the fifty-three gardens mentioned in the following list, and more than doubled at one of them. I ought, perhaps, to say why I have anticipated my own publication by compiling this list and forwarding it to you. There are several reasons, but perhaps the mention of three will suffice.

1. I venture to think that a gardener who has paid a little attention to the subject of rainfall has practical advantages over one who has not, and that is especially the case if he changes from one locality to another of which the rainfall is very different, and if a record of rainfall has been kept at the gardens to which he goes his advantage is very great.

2. I think that it will be interesting to all the contributors to the table, and to most of your readers, to observe the widely different fall at the various gardens, and I know that such information is useful in many ways.

3. I am aware that the table is far from complete even for

England and Wales, but I must not ask too much space, and besides that, there are many returns which have not yet been sent to me. I hope that the appearance of the table may remind those who have been accustomed to favour me with returns that the year 1877 is already a thing of the past, and that the sooner their returns are sent in the better. I hope also that those who have kept regular records and not sent copies to me will do so; and lastly, I hope that some who have not done so will resolve upon so doing. I promise them any help in my power.—G. J. SYMONS, 62, *Camden Square, London, N. W.*

TRANSPLANTING BROCCOLI.

AS I do not know whether the transplanting of Broccoli in autumn is general or not, I append the following, hoping that some of your more practical readers may give their experience upon the matter.

We had a piece of ground which we intended to renovate, but which was occupied with Broccoli that were planted about the middle of June, so that by the 1st of November the plants had almost attained their full size. We then had them lifted and planted in a border sheltered by a high wall. As other work was pressing we had not time to be over-careful about the operation, consequently many of the plants had not large balls. However, the plants do not seem to have been much disturbed and look nearly as healthy as another plot that was allowed to remain. In my opinion we shall have as good heads from those we lifted as from those that were undisturbed. We have had very mild weather since, which no doubt was greatly in their favour and perhaps may account for their freshness. There are some amongst those which were not lifted almost ready for cutting but none as yet among

the transplanted ones. The variety is Shearer's Late White, but I think any of the other varieties would bear the same treatment.—JAMES BOYD, *Callander Gardens*.

RAISING FERNS FROM SPORES.

HAVING carefully prepared the soil, and then roasted or boiled it in order to destroy all animal and vegetable life, it is placed in a Wardian case, or pan having a glass cover. The soil if roasted will require to be wetted with boiled or distilled water in order to be of a proper moistness. It is then pressed until there is a smooth surface, and after this sown with spores, which should not be covered with soil. All watering must be done from below—i.e., the pan placed in a saucer full of water, immersed about one-third of its depth; and this must either be boiled or distilled water, to prevent a confervoid growth on the surface, which would kill the young Fern germs. On the surface becoming green with growing Ferns transplant with the point of a knife into much larger pans, and this can be best done by making small indents in the surface, and placing in them small patches of the spores and lightly pressing each with a finger, taking care to wipe the finger dry after every pressure, or the young plants will cling to it. To procure new varieties spores are scraped off portions of a number of curious fronds or parts of fronds of the same species, and sown thickly together; and the reason for sowing thickly is that the germinal fronds by being pressed closely together by each other become more or less vertical, a position thought to be more easily fertilised by the male organs falling more readily into the female cells than when in a more or less horizontal position, as they would be if sown very thinly. Nature does to some extent provide for this by curling the thickened edges; yet under these circumstances, with thin sowing, the male spiral is more likely to be one from the same individual, and would therefore more probably produce a form identical with the parent germ frond; whereas, if the spores of many forms be sown together the chances seem to be much more in favour of the fertilisation by another variety being accomplished. After gathering the fronds for spores it is better to place them in drying papers for a day or two, and then scrape off the spores and sow immediately. Freshly gathered spores germinate much more quickly than those that have been kept for a time.—E. J. LOWE (in *Midland Naturalist*).

OUR BORDER FLOWERS—WOLF'S-BANE.

To have in cultivation the enumerated species of this family we should require a space of no small dimensions, for their names are legion, and many of them bear a great similarity to each other. They are a race of plants in all probability that has received as little attention as any in cultivation. Common we admit they are, but that does not detract from their beauty, for there is something about many of them that cannot fail to attract attention. Without saying all that might be said about their beautiful as well as their dangerous properties, for they are in possession of both, I may say that Monk's-hood—or, as it is sometimes vulgarly called, Skullcap, Devil's-cap, and Old-wife's-cap-and-pin—(*Aconitum Napellus*) is possessed of very poisonous properties, alike dangerous to man and beast. Linnaeus says the ancients, who were acquainted with chemical poisons regarded the Aconites as the most violent of all poisons. Wherever those plants are introduced they ought to be strongly marked. Dodonæus gives us an instance of five persons at Antwerp who ate the root in mistake and all died. Though the plant is thus invested with terror it can be subdued so as to become a powerful remedy in the hands of a skilful practitioner in some of the troublesome disorders of the human frame.

The plants are well adapted for large borders, shrubberies, shady walks, and open spaces among trees, but they should not be planted where cattle have access to them. When once established they require no further care, except that the taller kinds require staking when in open places to keep them from being broken by the wind. They are not particular as to soil or situation. They are readily increased by seed sown in spring either in pots or in a sheltered border in a sunny situation, or by division in the autumn or spring. They are a widely distributed family. To make a selection from such a host is no easy task. *Aconitum versicolor*, with its synonymes bicolour and variegatum, stands pre-eminent, and I think is the most attractive, being really a fine border flower. *A. paniculatum* is a noble object when in good trim. *A. pyramidale* is one of the best of the tribe. *A. lycocotum*, of a creamy

white colour, is quite an object of beauty in autumn. *A. ferox*, *A. autumnale*, *A. speciosum*, *A. Napellus*, and *A. N. alba* are all desirable border plants.—VERITAS.

WORK FOR THE WEEK.

KITCHEN GARDEN.

PLANT Jerusalem Artichokes in well-manured ground in an open situation but sheltered from winds. Light soil is most suitable. Plant 4 inches deep in rows 2 feet 6 inches asunder, selecting medium-sized tubers, placing them 15 inches apart. Fresh plantations of Rhubarb may now be made. The ground should be well trenched and very liberally manured, selecting healthy crowns with good roots, dividing the old roots into several parts. Plant 8 feet apart every way if the roots after a year's growth are to be taken up for forcing, 4 feet for those intended to remain three years, whilst the strong growers, as Monarch and Victoria, require 5 or 6 feet. Johnston's St. Martin is the best for forcing and early use. Light soil moderately moist affords the finest Rhubarb. Seakale that has been forced and is hardened off by having been placed in sand in a cool place for a few days should be planted. We plant in rows 18 inches apart and a foot apart in the rows. We also raise seedlings every year, selecting the strongest for forcing, planting out the smaller in rows 15 inches apart with the roots 12 inches apart, removing the bud from each before planting. These and the forced crowns ripen earlier, and are available for forcing sooner than plants raised from division of the roots or seedlings. Though we force Seakale and Rhubarb in a Mushroom house, keeping up a supply by introductions at fortnightly intervals, our principal spring supply is had by placing pots over the stools in the open ground and covering them with long litter so as to exclude air, but not so thickly as to heat; by covering a portion about twice as deeply as the other a succession is had. Chimney pots are employed for a portion of the outdoor Rhubarb, surrounding and covering them with any stale litter, or if wanted to come in quickly hot dung and tree leaves, so as to raise a gentle heat. Continue to dig or trench ground as the crops are cleared there being no doubt of the beneficial effect of the atmosphere upon soils with loose surfaces.

HARDY FRUIT GARDEN.

If the present mild weather continue no time should be lost in concluding the pruning of Gooseberry and Currant bushes which may have been delayed in hope of saving some buds from the birds. In pruning we contrive to have the centre of the trees open, with the branches 9 inches to a foot apart, cutting the sprays or young shoots to from half to three-quarters of an inch of their base, and shortening the end shoots and those retained for new branches about one-third their length. If extension be not wanted the shoots are cut back to two or three eyes. Black Currants require to have the wood thinned, cutting out the old bare branches to their base, which encourages vigorous young shoots upon which the finest fruit is produced. Raspberries should be finished pruning, leaving four to six of the stoutest canes to each stool, securing them to stakes 4 to 5 feet high, shortening the canes to that length. We also form a series of arches by bringing half the canes of each stool together, tying them together with tarred string, having the arches about 8 feet 6 inches high at the crown, merely removing the points of the canes. A stake 4 feet above the ground in the centre of the arches serves to make them secure against winds. By this plan the young canes have free liberty to grow without interfering with those bearing fruit. A liberal dressing of well-decayed manure should be given, pointing it in for a short distance around the plants, but in the open spaces it should be dug-in more deeply, yet not disturbing the roots. For preventing bullfinches taking the buds of Gooseberries there is no remedy so good as the gun, but the buds are made distasteful to the birds by sprinkling the bushes with quassia water, half a pound of chips boiled a quarter of an hour in two gallons of water; when cool strain off, adding six gallons of water, and whilst the trees are wet dust thoroughly with quicklime. It may be applied also to bush or pyramid Plum trees, and is good against insects as well as birds.

FRUIT HOUSES.

Pines.—Some of the suckers which were not strong enough for placing in fruiting pots last autumn may now be drawn upon, selecting the strongest and best rooted, shifting them from the 7 or 8-inch pots to 10-inch for Queens and 11 and 12-inch for those of stronger habit. Good sound medium-textured turf loam with the turf well reduced is the most suitable compost. It should be broken up tolerably small and had under cover some time to become warmed and in a fit state for use as to dryness. Place a layer of fibre on the crocks, and sprinkle it with soot to keep worms at bay. Keep the plants well down in the pots, and make the soil firm about the roots, and with a bottom heat of 85° they will speedily be established in the fresh compost. 60° to 65° will be a sufficiently high night temperature for these plants as well as for those potted last autumn, with the usual rise of 10° to 15° by sun heat. Examine the heat in the beds where plants are starting into fruit, seeing that it does not exceed 90° or 95° at the

pot bottoms; if the latter temperature be indicated the pots must be partially withdrawn until the heat has subsided.

Figs.—Those in pots started early in the month will be showing their young shoots. To keep them stiff and short-jointed afford them a light position and admit air freely. Weak liquid manure may be given when the first leaves are full-sized. We have grown Figs in pots very satisfactorily upon the back flue in a Pine stove, the pots being placed on bricks to prevent overheating. They were introduced early in February; the temperature was never less than 60° rising to 80° and 85° by day. Weak liquid manure was given liberally. Figs in pots do equally well placed on the hot-water pipes in a vinery if the roof be not densely crowded with Vine foliage, as Figs to do well require plenty of light and heat. In the Fig house, early fruit being desired, the trees may now be started, syringing them twice a-day unless very dull, when once a-day is sufficient, maintaining a night temperature of 55° to 50°, and 70° to 75° by day from sun heat.

Strauberrries in Pots.—The earliest plants will be throwing up the trusses of flowers, and should be duly supplied with water, air being given on every favourable occasion; indeed, until the fruit has set and is swelling freely every opportunity should be taken to afford ventilation. Plants this year show a disposition to make a quantity of leaves before the flower scapes appear above the crown, which is usually due to undue excitement in the early stages of growth, though it may be owing to the unfavourableness of the late summer and autumn for ripening the crowns. This points to the advisability of bringing the plants on very gradually, employing very little fire heat in the case of newly-started plants, and no more of it than is necessary to induce steady progress until the fruit is set and swelling. Keep the atmosphere rather dry when the flowers have expanded, and run a bunch of feathers, or the hand, over the flowers to distribute the pollen more equally and prevent if possible deformed fruit. Introduce batches of plants to vineries or Peach houses for succession, and if the plants have been started in bottom heat to promote activity at the roots see that the pots are not too suddenly withdrawn from the fermenting material; if on inverting the pots we find the roots healthy and active among the drainage, bottom heat for starting the plants is not required. Plants in frames to be well ventilated, and if dry to have a good watering.

PLANT HOUSES.

Greenhouse.—Fuchsias that were dried off in the autumn should now be pruned, cutting them well back. Placed in a gentle heat they will soon break, and when they have shoots an inch long repot. They will flower earlier than the plants from cuttings struck last year. Another lot of the old plants may be held back to succeed those first started, which will afford a succession, they too flowering before the young plants. Camellias in pots should be well supplied with water when in flower, and if additional pot room be required it must be given before new growth is made. In potting merely remove the old effete soil from the surface and from among the roots, draining efficiently, and firming the soil well, or the water will run through the new material without wetting the ball. We use light turfy loam pared off very thinly (an inch) three parts, sandy peat a part, and a sixth of old cow dung. Remove the loose surface soil down to the roots of any plants that do not require to be potted, and top-dress them with light fibrous loam and cow dung not less than a year old in equal parts, and make firm. The leaves on both surfaces should be sponged to remove any dirt or insects. Introduce from frames *Primula cortusoides amena* vars., repotting them if not already done; also *P. denticulata*, *P. nivalis*, and others of the alpine species, which are quite charming. They require light airy positions, and must not be allowed to become dry. *Primulas*, *Cinerarias*, and *Cyclamens* throwing up bloom will be much benefited by the application of weak liquid manure. *Liliums*, *Tritonias*, &c., which have been kept under stages or plunged over the pots should be placed in the light before they have made much growth, or they will be drawn up weakly. If a few pots of *Lilium auratum* and *L. longiflorum* are introduced to gentle heat they will come in early and be very acceptable for this structure or the conservatory. *Cytisuses*, *Acacias*, and *Eriostemons* keep well supplied with water, and any Heaths pinched for pot room, especially those commencing to grow, should be potted. It is much better done early than late, as the plants have an opportunity of becoming established in the fresh soil before the sun becomes powerful, and will flower much stronger than plants with the roots in a cramped starved state. The fast growers require more pot room than the close-growing hardwooded varieties. Pot very firmly, draining thoroughly, watering carefully for a day or two before potting, so as to have the soil in a proper state.

Conservatory.—*Passifloras* should now be cut in pretty closely. They break freely if cut back to an eye or two of the old wood, often from the stem. The shoots resulting should be thinned, so as not to allow too much crowding, and with thinning and regulating occasionally they will commence flowering in June and continue to the end of the season. *Tacsonias* to have the wood thinned-out, cutting away the old shoots which have flowered, training young shoots in their place. *Habrothamnus fascicularis* and others are fine ornaments for walls, pillars, or roofs. The

roots of these and most climbers in conservatories being confined to narrow limits should have copious supplies of water and liquid manure. A good supply of flowering plants ought to be kept up by introductions of forced plants, such as *Azaleas*, *Deutzias*, double *Peaches*, *Spiraeas*, *Lily of the Valley*, bulbs, and other forced plants, with *Cyclamens*, *Primulas*, *Genistas*, *Epacris*, *Acacias*, *Correas*, &c., that may be draughted from the other plant structures. See that the foliage of the permanent plants is clean and free from insects, remove decayed leaves and flowers, and let neatness and order be scrupulously attended to at all times.

Forcing Department.—Introduce another batch of *Lilacs*, *Prunuses*, *Deutzias*, *Guelder Roses*, *Sweet Briars*, the fragrance of which is highly esteemed in the conservatory, *Ghent Azaleas*, *Rhododendrons*, *Kalmias*, *Dielytras*, and bulbs. A few plants of *Indian Azaleas* should be introduced, selecting those with the flower buds in the forwardest condition, also a good batch of *Roses*, particularly the *Tea-scented*, and some pots of *Musk*. Mulch the surface of the pots of the *Roses* with rich compost, and water with weak liquid manure. Temperature 60° to 55° at night, 65° by day, with a rise from sun heat to 75°. Keep up a good moisture by sprinkling every available surface twice, and in bright weather three times a-day. Another batch of *Amaryllises* to be started, than which few plants are more useful, not forgetting, as is too often done, *Jacobaea Lily*. Our plants of *Hippeastrum pardinum* which flowered in September are now sending up flower scapes strongly. We keep the plants on shelves near the glass, and never allow them to want for water, feeding them with liquid manure when in growth. *Tuberoes* should be potted, employing 6 or 7-inch pots according to the size of the roots, removing the suckers and side eyes, covering the root all but its point with soil, which may be turfy loam with a fourth of well-decayed manure. Plunge the pots in bottom heat (75° to 85°), not watering until growth takes place, keeping them in the hot-bed until they show the flower stems, when gradually withdraw, feeding the plants with liquid manure; 60° should be a minimum temperature, rising to 75° or more from sun heat. We prefer the American roots, *Pearl* being a stout dwarf variety, with pure white double flowers, and very sweet.

FLORISTS' FLOWERS.

Auriculas.—The month of January is a period at which the *Auricula* does not look so well as at other times. All its summer leaves have gone; week after week the cultivator has gently removed them as they have withered away, leaving only a stout heart from whence by-and-by will be developed in a marvellous way the flowering plant with its fine truss of bloom. There is no leaf-action at this period, but the grower will go carefully through his plants, occasionally brushing-off any green fly, looking-out for any slugs or vermin that may have intruded themselves, and preparing for the important work of top-dressing. The surface of the soil should be loosened with a plant stick, and then shaken out to the depth of a couple of inches or more, the roots being disturbed as little as possible, and the space being filled-up with fresh compost. About the character of this there is a difference of practice. Some growers use pure well-decayed sheep's dung, others simple loam, and others a mixture of loam and manure with a little sharp sand: the latter is perhaps the best. The whole collection having been gone through, and any good offsets taken off, the pots are replaced, a gentle watering is given, and in a very short time the effects of this treatment assisted by the returning spring will be very manifest, and pleasurable anticipations of future beauty will cheer the cultivator.

Carnations and Picotees.—There is not much to be done at this season. Air should be given at every favourable opportunity, and the plants and pots kept perfectly clean. The surface should be gently stirred to prevent the growth of moss; in fact, cleanliness is the one point to be aimed at. Those who grow their collections in pots will now see that these are all clean and sweet, and will have their compost under cover. The best mixture for their growth is one of three parts loam and one part of old manure. Some growers use leaf soil and also road grit, but as a rule the simpler the compost the better. It should all be carefully passed through the hand so that any wireworms may be detected and destroyed, for they will otherwise very soon destroy the plants, and in the fresh loam they are apt to be present. Those who grow their collections in beds will look through them to see that neither worms nor frosts have worked them out of their proper position. In wet days stakes may be looked over, painted, and made ready, and labels prepared, so that when the really busy time comes there may be no need of preparation.

TRADE CATALOGUES RECEIVED.

Galloway & Graham (late Robertson & Galloway), 138, Queen Street, Glasgow.—*Descriptive Seed Catalogue and List of Choice Gladioli.*

W. Tait & Co., 45, Capel Street, Dublin.—*Spring Catalogue of Vegetable and Flower Seeds, Potatoes, Implements, &c.*

Stuart, Mein, & Allan, Kelso.—*General Catalogue of Forest and Ornamental Trees and Shrubs, Roses, and Select Gladioli.*

George Cooper & Co., Chiswick Seed Warehouse, Derby.—*Catalogue of Kitchen Garden, Agricultural, and Flower Seeds.*

W. W. Johnson & Son, 5, Bridge Street, Boston, Lincolnshire.—*General Catalogue of Vegetable, Flower, and Farm Seeds.*

W. Hean & Quick, Barnstable.—*Illustrated Catalogue of Garden and Agricultural Seeds.*

W. P. Laird & Sinclair, Dundee.—*Catalogue of Vegetable and Flower Seeds, Potatoes, and Garden Requisites.*

Ormsby & Renwick, Melrose.—*Catalogue of Vegetable, Flower, and Agricultural Seeds, Implements, &c.*

F. Gallop, 80, Western Road, Brighton.—*Catalogue of Vegetable, Flower, and Agricultural Seeds.*

Bruant, Boulevard Saint Cyprien, & Poitiers, France.—*List of New Pelargoniums, Petunias, Penstemons, Verbenas, &c.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

ROSE SHOWING (*A Lover of Rose Shows*).—We are quite sure that neither you nor "WYLD SAVAGE" intended to write caustically, so the subject had better rest. Lord Melbourne's suggestion was a wise one, "Cannot we let it alone?"

CYCLAMEN FLOWER (*Mrs. C. W.*).—It was pressed flat; the petals always are reflexed. The natural colour of the *Myosotis* flower is pink, and sports from it, such as the blue, will return occasionally to the natural colour.

MRS. PINCE VINES FAILING (*J. Mark*).—It is the shade of the Black Hamburgh Vines in front of the Mrs. Pince Vines on the back wall that has caused them to fail. They may be removed at any time, and at their age no satisfactory results would follow planting them in another position. It will do no harm but good to the Hamburghs to remove the Vines from the back wall if you root them out by taking a trench out 3 feet wide all along the back the depth of the border, and fill up the opening afterwards with a mixture of good loam, decayed manure, and ground bones. We have watered Vines with weak manure water after the fruit had commenced colouring without injuring the flavour, but when the fruit is ripe pure water only should be applied to the roots.

ASPLENIUM (*Fern-Grower*).—The two species you name are not identical.

NERTEA (*T. S. C.*).—The emphasis is on the first syllable. It belongs to the natural order Cinchonaceae, and was named in honour of a German. Refer to the dictionary for Catalpa.

SOIL INFESTED BY GRUBS (*G. S.*).—Apply salt and guano at the rate of twenty bushels of salt and 5 cwt. of guano per acre.

SELECT PELARGONIUMS FOR EXHIBITION (*Devonshire Subscriber*).—Beauty of Oxtou, Queen Victoria, Album plenum, Troubadour, Othello, May Day, Highland Lassie, Achievement, Jubilee, Ruth, Maid of Honour, and Robin Hood. Six fancy Pelargoniums—Lord of the Isles, Lady Dorothy Neville, Mrs. Mendel, Acme, Fanny Gair, and Vivandière.

SELECT HERBACEOUS PHLOXES (*Idem*).—Six early-flowering—Waverley, Mrs. Dennis, The Queen, Maive Queen, Purple Emperor, Mdlle. Bertha, and Rendaler. Six late-flowering—Mrs. R. Grieve, La Avenir, A. F. Barron, Queen of the Whites, Mrs. W. Miller, and Lierwall.

CUCUMBER ROOTS DISEASED (*T. H.*).—To attempt applying a remedy to Cucumber roots badly affected with excrescences is to waste time needlessly. Raise fresh plants from seed, not from cuttings of the affected plants, which destroy. Remove the whole of the soil, give every part of the interior walls a thorough dressing with hot lime wash, scour the whole of the woodwork, close house, and fill it with fumes of sulphur; then put in some fresh sweet soil and your fresh plants will probably prove quite healthy. We cannot tell if the soil sent contains any noxious insect, but we advise the exercise of due caution in the subsequent selection of soil.

MEALY BUG ON CUCUMBER PLANTS (*Idem*).—The same treatment must be applied in this case as in that of the plants with diseased roots.

PROPAGATION OF MENTHA PULEGIUM (*John Brown*).—Your plants upon which you have seen no leaves may not be dead. Place them in gentle heat and the matter will soon be decided. If they put forth growth make cuttings, which root readily in a lively temperature and soon afford other cuttings. They may also be increased by division of the roots. Although this plant is hardy it suffers from excessive wet during winter and early spring.

PRUNING YOUNG PEACH TREES (*A Constant Reader*).—If the growth is vigorous it should only be slightly shortened, but if weakly severe pruning must be practised. We gather from your note that your trees are vigorous, and therefore would not reduce the shoots of 3 feet long which you mention more than 3 or 4 inches, thinning it out to allow sufficient space for new growth, pruning the shorter lateral shoots slightly, and thinning them freely. Let the lower leading shoots be left considerably longer than those near the centre of the tree in order to secure an equal distribution of vigour.

ARBUTUS FRUITING (*A Lady*).—*Arbutus Unedo* is a native of Ireland, and under favourable circumstances may be seen in the early winter months laden with pendant clusters of scarlet berries. An unfavourable autumn or premature cold will so much affect the flowers as to destroy all chances of fruit. Yours is the true kind, and the invariable barrenness of all your shrubs is doubtless owing to an unfavourable position. Transplant one or two into sheltered sunny nooks and you will probably be rewarded by obtaining some of the fruit which has so justly excited your admiration.

GLASS RANGE AGAINST A HOUSE (*A Subscriber for Twenty Years*).—As you wish to see the flowers from the windows, the height of these must in

some measure be your guide as to the height of the glass houses, upon which, too, the height of the house itself should exercise some influence. Why should you make the central portion lower for the bedding plants when they can be brought as close to the glass as you like by means of staging? Rather would we see a more important aspect imparted to the centre by means of an octagonal bay projecting from the front of the range in harmony with but somewhat longer than the octagons at the ends, which we much like, and we think that for the portions between the octagons a half-span would be much better than the more formal lean-to form.

HEATING GREENHOUSE AND PIT—TRANSPLANTING VINE (*W. E. B.*).—1. According to your arrangements there will not be sufficient heat in your frame to grow winter Cucumbers. To do this the pipe would require to go along both back and front, and the same quantity of piping would be required along the bottom of the bed to supply bottom heat. 2. There will be enough piping in the greenhouse to keep up a minimum heat of 52°. It will be much better for the plants to have the boiler outside the house, but close to the end of it. The boiler you contemplate putting in will meet your arrangement very well, but you would find the heat act much better if the pipes were taken along the front of the house than the back of it. 3. If lifted and transplanted very carefully your Vine may be moved without injury, providing it has not started into growth before that time. A border both outside and inside would be an advantage.

CULTURE OF VEGETABLES (*J. Lansell*).—There are quite enough of books published to meet the demand.

TEA ROSE CHESHUNT HYBRID (*Chimber*).—Cheshunt Hybrid is suitable for a wall, is very vigorous, bears its large flowers abundantly, and is quite worthy of a south-west aspect.

USE OF SHADED BORDERS (*D. C.*).—Your borders outside the garden wall facing the north and east and much shaded are precisely such as gardeners value for securing a late crop of Strawberries. Black Currants would also answer well in such a position, as would Violets and Lily of the Valley.

ASPHALTING BOTTOM OF A VINE BORDER (*Idem*).—Yes, asphalt will answer well if it is necessary to place a substance impervious to roots beneath the border. It is, we may remind you, only requisite when the border overlies cold heavy clay or marl. Upon a gravelly or rocky substratum a concrete substance is an evil rather than a benefit. Take care that the asphalt slopes from back to front of the border, and that the drainage is thoroughly efficient.

PAYMENT FOR TRENCHING LAND (*Idem*).—Light soil, 16 inches deep, 10d. per square perch; medium soil, 1s.; and heavy soil, 14d. We have lately had an acre of medium soil trenched at the rate we quote, and the men, who were picked skilled labourers, by working hard earned a pound a-week. Weakly or unskilled men could not have done so.

"SCARLET" PRIMULAS (*W. Harris*).—The blooms sent are very good both as to size, form, and colour. The colour is rich red vermillion suffused with rosy purple at the base of the segments, the eye being deep orange. Fertilise the best-formed flowers with pollen from those having the brightest colour and you will produce varieties worthy of being submitted to the Floral Committee of the Royal Horticultural Society. You possess an excellent strain.

WHITE CYCLAMENS (*H. J.*).—The flowers are pure, well formed, and attractive, but rather small. The strain, however, is good, and with careful selection and good cultivation you will certainly obtain "something worth looking at."

NAMES OF PLANTS (*J. O.*).—1, *Lamium purpureum*; 2, *Veronica Bux-banani*; 3, *Euphorbia Peplus*. (*Juvenile*).—*Taxonia eriantha*. (*J. M.*).—*Chelanthus* sp. (*W. M. B.*).—It may be a species of *Westringia*, but the specimen is insufficient. (*J. F. Cromwell*).—The Fern is immature. The flower is *Alonsoa incisaefolia*. (*Mrs. L.*).—A form of *Lastrea spinulosa*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

MANAGEMENT OF PASTURE AND PARK LAND.

PASTURES on sandy land require to be treated very much in the same manner as those on gravel soil; they are, however, oftener found to require a dressing of chalk or lime as well as earth, and the earth should be nearly approaching clay if it can be readily obtained, as it prevents the effect of drought in summer, especially when the subsoil is composed of sand as well as the surface. When, however, the sand surface rests on chalk or sandstone the land is more holding, and we find the herbage much sweeter, and it does not produce weeds and sour grass so profusely as the sand soil, which runs to a great depth.

We will now refer to pastures and meadows more particularly resting on peat, and commonly called peat mosses. These if totally neglected are amongst the poorest we meet with, but they may be made exceedingly productive, first by draining; and the drains should always be placed deep enough to place the tiles below the peat stratum in any soil which may be found under, whether sand, gravel, or clay may underlie. Unfortunately drains placed in the peat soil are nearly sure to be stopped and clogged with red ferruginous deposit oozing out of the peat. We find the drains act well, however, when the tiles are placed in a substratum of gravel, clay, &c., and covered with the same instead of covering-in with peat. When drained, peaty pastures should have a heavy dressing of any earthy substance: clay or gravel will

answer, as it presses the spongy peat and makes it fertile, giving it a substance, and even in the after-management a dressing of fine gravel will do more good than a coat of yard dung. We have now land as good pasture as may be desired which has never been manured, only clayed and gravelled occasionally. This is explained by compressing the peat, which is no more or less than vegetable matter in decay, and this when made dry and compact yields plant food largely and constantly. We often find productive water meadows resting on peat, and the process of irrigation is the cause of their fertility. As there are continually earthy deposits left by flood water, these meadows without irrigation are comparatively worthless and grow the coarsest of grasses. The last soil we shall name as pasture is marl, which is a kind of clay with some lime in it, but on account of the close and heavy nature of the soil it often yields very poor pasture, but when it is assisted by manure such as guano and nitrate of soda it becomes very productive. Pastures resting on marl do not require bone or mineral superphosphate, because the lime they contain varies from 10 to 25 per cent., and when ammoniacal manures are applied the grass strikes its roots deeply into the soil and derives benefit from the lime, and potash too, for heavy soils usually contain more or less of potash. It sometimes happens that these heavy lands, whether of clay or marl, after great neglect show but little herbage, and where the grasses have died out they should be renovated by sowing seeds adapted to the soil. We, however, cannot now name the sorts of grass seeds we recommend, as we hope under the head of "Laying Down Permanent Pasture" to give them in detail at a future time. In alluding to pastures generally we must include all the varieties of soil, and but few of them have been so managed as not to respond readily to the application of manure and compost. The difference in the value of hay and grass where the quantity of produce is the same is only to be accounted for by reason of the nature or latent value of the soil. This difference, however, leads us to think that we may give the land artificially that which it is deficient in naturally, and all our previous observations lead up to this point, which we consider ought to be the study of the farmer or manager of pasture or park land, otherwise it is very easy to throw away money in applying substances called manure injudiciously and indiscriminately selected. Our own experience induces us to recommend that Peruvian guano is the best artificial manure for pastures in general, nitrate of soda and bone superphosphate next best; and this selection is fully borne out by the experiments of all those whose statements can be relied on. We use from 2 to 3 cwt. per acre of guano, and of nitrate and superphosphate 2 cwt. of each, and this as an annual dressing will keep almost any pasture or park land in a productive state. We have always noticed that the oldest pastures are more productive than those which may have been recently laid down. This will be evident to any observer who will examine the earth immediately under the surface, for in all old grass land there will be found a kind of humus or vegetable mould, often an inch or two in thickness, formed by the annual decay of the roots of the grasses; and this in some soils has been going on for generations, giving the pasture a fertility which is totally absent in recently-made pastures, and in the latter case rendering a dressing of manure an actual necessity almost every year to obtain full crops of grass.

The method of stocking pastures is important, as well as the period of feeding, and to maintain all the best grass in the soil the pasture or park land should be fed with cattle and mown for hay alternately. When appearance is the chief point, as in park land, it may be requisite to feed every year, as grass crops and haying are sometimes considered unsightly objects. Cattle and sheep may often be fed together with advantage, and if so it should be in the summer months whilst the grass is full of growth. Cattle may feed the pastures in the winter months when the weather is dry enough; but sheep should be kept entirely out of grass land in the winter and early spring, as they bite so closely as to damage the heart of all the best and finest grasses. Horses also eat the grass down very bare, and we have land under our own care which has been doubled in value of produce during the past three or four years by entirely excluding the sheep both in summer and winter, and being fed only by dairy cows and cattle. Wherever cattle are feeding the droppings ought to be collected every few days and taken to a compost heap for future use, otherwise when the dung is allowed to remain and the grass to grow through it comes very unsightly, and large bunches of grass are left unconsumed. This grass runs to seed heads, which often produce "ergot," and this is very prejudicial to cattle when eaten, and with dairy cows it is often the cause of casting and premature birth of the calves. In order to prevent this calamity and to enable the aftermath or latter growth of grass to come with regularity, the tufts and bunches of grass not fed down should be mown down with the scythe and carried away for bedding or such-like purposes. It is, however, when required given to horses, and they will eat readily what the cows refuse; in fact horses are often turned in to eat the clumps of grass when the pasture is not required for the dairy cows for a time. We omitted to notice

above the practice of boneing grass land as done in Cheshire and other counties, where as much as £10 per acre has been expended in one dressing of coarsely broken bones. These without doubt effect a lasting and permanent value of the pastures; but we prefer the mode of annual dressings, as £10 per acre is a large investment which many persons cannot afford. Besides, it ought first to be a matter of experiment as to the result of so large and costly a dressing, for we have found that this application has not answered the purpose in some instances, whereas in others it has doubled the letting value. Where pastures have been dressed with dung and compost it is always necessary that it should be carefully and regularly spread, and as soon as the weather will permit the ground should be chain-harrowed. The chain harrow is a capital implement and a great improvement upon the old bush harrow of former times. Before laying-up for hay all grass land should be carefully looked over, picking stones, sticks, and all extraneous matters, and at weeding time docks and all weeds, together with all roots of brambles, furze, &c., should be taken up with a small pick, pointed at one end and a sharp edge 2 inches wide at the other end. This is the only implement we ever allow in use for weeding of all crops, whether of grass or grain, as the common weeding spud often used cripples the weeds but never eradicates deep-rooted plants such as docks, brambles, &c.

The fencing and division of pastures and park lands is important in various ways, keeping the cattle within certain bounds in one case; in others the ornamental part of the question crops up, and anything unsightly would be often instantly rejected. Iron fencing is now much in use, and we have had a great deal of wire fencing put up, not only for temporary protection to fresh-planted quicksets, but as permanent fencing; but we do not recommend it except for cheapness, having known very serious accidents occur to valuable cattle. We, however, prefer the flat-barred iron fencing, which is very strong and durable. The cattle can see it better, and are entirely deterred from attempting to pass over or through. It is the truest economy in the long run, for wire fencing, although cheap to erect, is continually requiring repairs, and we do not like to trust valuable stock, either cattle, horses, or sheep, within wire fencing only.

WORK ON THE HOME FARM.

On the light soils it is not too soon for the planting of early potatoes, the horses will consequently be employed by drawing manure to the field. When the weather is favourable it is none too early to put in beans, peas, summer tares, &c., which will engage the horses in ploughing for some little time. At this early period we do not trust to ploughing before planting and sowing, as any little change in weather, whether of frost or rain, delays the seed time on a stale furrow; but the work is best done by finishing daily at one operation by ploughing, planting, and seeding the land. For this work the small drill attached to the plough depositing the seed in the furrow answers a good purpose. Any manure not laid out on grass should be carted out, the sooner the better, and before the horses become entirely engaged in tillage work.

Hand Labour.—The men will now be required to assist in preparing manure for the spring crops; guano to be broken down fine for the potato crop and the pastures. This may, however, by anticipating the requirements, be done when the men are driven to the homestead by wet days or storms, as we hold it to be good policy to pay the men for their whole time, finding them work under cover instead of deducting wages for wet days. To make this answer the farmer's purpose it only requires a little foresight, so as to get all work which can be done under cover completed in readiness for fine weather. Breaking guano and passing it through a half-inch sieve or screen is important, for if large lumps are sown on the land they only destroy vegetation for a small space instead of properly manuring a larger space. Other winter work if not finished should now be completed, such as banking, hedging, trenching, trimming the quicksets, &c.

The shepherd, too, will be fully engaged, whether with an ewe flock or dry flock. If with the former the lambs from Hampshire and Sussex downs will now be falling and require his constant care and attention; and this is not a matter to be left to the shepherd entirely, as few men take sufficient interest in the work as to be trusted without the supervision of the master pretty constantly, even if they have had sufficient experience. The management, however, of a dry flock, either for stock or fattening, is a more simple matter, but still requiring unremitting attention of both men and master. Foldyards will now have to be provided for all the flocks which are lambing and about to lamb. Our mode of making the fold is by a double line of hurdles stuffed with straw between the lines; or if with a single line of hurdles bairns set on end attached to the hurdles may answer; but the fold should always be made in a sheltered spot, and if near the shepherd's cottage or farm homestead so much the better. In order that the fold may be always as dry as possible we place at the bottom 8 or 10 inches of mould or sand, and then litter with straw as required; but when the fold is placed on sloping land less litter and less earth is required, because all moisture drains away readily. Sand spread over the fold as well as straw every

Women may now be employed in picking stones, sticks, &c., on the pastures, as these are impediments in mowing the crop for hay. They may also be employed in preparing carrot seed, which we have done by hand-rubbing with harvest gloves, to divest the seed of the burr, and when winnowed the seed will drill freely. This we prefer to mixing the seed with the manure, ashes, &c.

We are approaching the time of year at which in England we have the worst of our frost and snow. Especial management is then necessary for poultry; for the breeding season being at hand, or in yards where very early chickens are desired having actually begun, any carelessness is sure to throw back the laying hens and to do much harm. If possible a master or mistress should always rally forth in bad weather; example does much and shames others into activity. To begin with. Put down straw in the house; barley and oat straw are best for this purpose, it keeps the birds' feet free from cramp, and an occasional handful of corn thrown amongst it gives them employment in scratching. Water must be given twice a-day in small quantities, and every pan emptied at sunset, or they may be frozen and cracked. Food should now be chiefly soft, the birds are unable to find sufficient grit to help them in digesting hard food. A good feed of meal given twice a-day, warm if possible, and some kitchen scraps are the best diet. Watch the hens that they do not peck the cocks' combs; this vicious habit is generally contracted during cold, when insect food is not obtainable. A cock so treated must be at once removed and kept by himself till the wound has completely healed. Green food is of course desirable if you can spare it soft and good, but better let them go without it than give tough frozen grass or vegetables, which bring on hardness of crop. If the weather be sunny sweep away the snow for a few yards round the house, and if there be a sunny corner or bank near sweep a way to it. We have little idea of the warmth there is close to the ground in sheltered spots, and a few hours' sunshine in such a place is to them as pleasant as a stroll on the Italian Riviera to us. If the winds are piercing and the houses in exposed situations keep them entirely closed. A little common sense in such matters is worth much, and if it be duly exercised the birds will come out at the thaw none the worse, revel in the then-uncovered grass, and begin laying at once. On the other hand, if they are neglected, left exposed to every wind, and denied water, they shiver about in misery, eat snow wholesale, which brings on violent dysentery, and are thrown back for weeks.

The power of enduring cold which fowls reared in a truly hardy manner have is wonderful. We have had Golden Hamburgs sleeping in the trees through long and severe frosts, though through the day they generally congregated in a shed looking south to lay in a store of heat; but then they had never known coddling. Game Bantams, too, we have had which for years always roosted in Portugal laurels, and once during a famous snowstorm when the thermometer went down almost to zero a White Bantam cock lived aloft for many days without food, taking long flights from tree to tree, but never daring to come down. This, it is almost needless to say, can only be allowed with impunity in the case of birds which have long been unhouased and so gradually hardened; such birds seem to have perfect immunity from coughs and colds.

Never turn out a bird after exhibition into a cold house ; its comb will probably be frost-bitten the first night. We had a noble Dorking cock spoilt in that way. He had been penned up a fortnight to hasten the moult in a warm place, and the very first night he went out unfortunately proved the coldest in an otherwise mild winter ; the end of every peak on a faultless comb was frost-bitten and came off. Another similar accident we had not long ago. A bird purchased at Birmingham was sent in an unlined basket, met a cold wind on a cart's top, and in consequence lost the greater part of his comb. In the latter case the mischief might probably have been avoided if the bird had been kept in the dark and not taken into too warm a room. Guinea Fowls appear to suffer much in the feet from cold. If you can coax them into a building keep them there. Ducks, too, which are hardy enough against all inclemency of the skies, are often cramped from standing on ice or icy ground ; a thickly-strawed bed is all they require.—C.

THE sixth annual Exhibition was held on January 23rd and 24th, in the Skating Rink, at the Bell Hotel, Maidstone, when the following prizes were awarded :—

POULTRY—DORKINGS—Coloured—1, H. Stephens. 2, G. W. Greenhill. 3, E. Rice. *Silver-Gray*—1, F. Cheesman. 2, Mrs. Wachser. 3, J. Boulding. *White*—1 and Cup, B. A. Boiesier. 2 and 3, Mrs. W. Stratford. **COCHINS—Buff or Cinnamon**—1 and Cup, G. Dowker. 2, Mrs. A. Christy. 3, C. M. Stickings. *etc.*, F. M. Cobb. *Any other colour*—1, B. A. Boiesier. 2, Miss Mansel. 3, W. A. Tucker. **SPANISH—Black**—1, J. Francis. 2, C. W. Hammond. 3, F. Cheesman. **BRAHMA—Dark**—1 and Cup, Miss E. Shooter. 2, F. Lake. 3, J.

JUDGES.—*Poultry and Pigeons*: Mr. R. Teebay. *Cats and Rabbits*: Mr. G. Billett.

st Exhibition was held in the Corn Exchange, Yeovil, on 23rd and 24th, and we are informed was a very successful one. It numbered 450 pens of poultry and 800 of Pigeons. The place was decorated for the occasion, and visitors were very numerous.

JUDGES.—*Poultry*: Rev. G. F. Hodson. *Pigeons*: Mr. P. H. Jones.

THE annual Exhibition was held on the 26th inst. Wolverhampton has always been regarded as one of the most important shows in the midland counties; and the absence of Bristol from the list this year, a Show that offered good prizes and peculiar advantages for late-hatched birds, has led many to expect unusual things from Wolverhampton. The Show was held in the Agricultural Hall, and the management was, as usual, all that could be desired. We are pleased to add that the attendance of visitors on the first day promised to give the Committee a substantial return for their liberality.

The Judges were for poultry Messrs. Hewitt and Nicholls; Pigeons, Mr. Allsopp.

Game cocks occupied the first place in the catalogue, a strong class of twenty-two. The prizewinners were all birds of great merit. Black Red cockerels were a good lot, but we liked the class for Brown Reds better as exhibiting more style than the

former. *Dark Brahmas*.—Cock and hen an excellent class, the cup going to a beautifully marked hen with a large well-shaped cock a little grizzled in the thighs. Second we think contained the winning hen at the Palace with a fair cock. Cockerels were a large class of nineteen. We noticed here that many former winners were very much out of condition and rough in plumage, evidently the effect of overwork. The winner was a nice-coloured bird with plenty of leg-feather without the objectionable vulture hock. The second was good in shape, style, and colour, but rather loose in the wings. Third a mottled-breasted bird with a very neat head and comb. Pullets were not equal to the cocks. First was clear in markings, but had too much hock to please us; second also good in markings. *Lights*.—The old class was very meritorious, the cup going to a splendid pair. The second we thought almost equal to the first. Cockerels, sixteen entries.—First a fresh-looking bird, well feathered and free from hock; second a well-shaped bird, but heavily hocked; third a good bird, but very creamy. The pullets were again behind the cocks in quality. The winner was good in colour, size, and shape. Second small but pretty. *Dorkings* were not numerous; the cup was awarded to a good pair of Coloured. *Cochins*.—Buffs, with the exception of the cup pen for old birds, did not strike us as showing off more than ordinary merit. Partridges, on the other hand, were splendid classes, Mr. Wood taking a large share of the prizes with some well-known birds. The White were also very superior, the first being very large and pure in colour. Blacks were good in numbers, and we noticed a marked advance in the cultivation of this colour, many of the birds possessing characteristics equal to the Buff. The hen in the first-prize pen was very large, well feathered, and good in shape. The winners among the chickens were superior in almost all points. *French* capital classes, *Houdans* the most numerous, but *Creves* the best. *Spanish* were, as might have been expected, splendid classes. This season of the year offers special advantages to this variety. Old and young should be now, if ever, in splendid condition. The Crystal Palace winner in the old cock class was just looking his best. Hens a splendid lot, but we thought Mr. Jones's highly commended pen should have been first. *Polish*.—First a handsome pair of Silver-spangled with immense crests, second Blacks, also good. *Variety class*.—A pretty pair of Brown Leghorns were first, a large pair of La Fleche second, a pair of Cuckoo Cochins third. The Selling classes were well filled and offered some splendid investments, many of the birds being fit to win in the open classes. The first Spanish cock and the pair of hens here would have been quickly claimed at the Crystal Palace at three times their restricted price. *Ducks*, first an immense pair of Rouen, second Aylesbury. The Variety class contained some very admirable specimens. *Hamburgs* should be mentioned as deserving considerable credit. The cup went to Blacks, which did not appear to give satisfaction to the majority of the exhibitors of this variety. Game *Bantams* were few, and with the exception of the first-prize pen we thought them only moderate. *Sebrights* were a charming lot. First a pair of Silvers, neat in combs and beautiful in lacing. In the Variety Blacks were first.

Pigeons disappointed us very much, not any of the classes calling for special mention. Wolverhampton is so near Birmingham, one of the centres of the Pigeon fancy, that we expected a much more spirited competition.

HARE AND RABBIT HYBRID.

SOME of your readers who take an interest in Rabbits may like to know that I have in my possession a very handsome doe Rabbit, aged ten months, the result of a cross between a jack Hare and a tame doe Rabbit. It is double lop (very long), of a grey colour, and weighs between 8 and 9 lbs. As I saw in your Rabbit Manual that the Curator at the Zoological Gardens could not effect a cross between the Hare and the Rabbit, I presume this is rather a novel fact.—D.

PIGEON LAYING FOUR EGGS.

As the laying and hatching of four eggs by one Pigeon at one time seems really an unusual occurrence, perhaps you may like to have the whole of the facts, so that the case may remain on record for the information of naturalists and future inquirers.

Four young Antwerps were given to me by a friend. When they became old enough two of them paired, only one of the four being a hen. I had no other Pigeons. This hen laid four eggs, two of which she turned out of the nest and sat on the other two, which, however, proved clear. She soon began to lay again, and again laid four eggs, and hatched them all. While she was sitting I obtained two more hens, which immediately paired with the two remaining cocks. These new hens laid and are now sitting.

There was no other hen in the house when the first one laid the four eggs, neither is it possible that any strange hen could have had access to the nest, nor could any person have tampered with the nest, as it was in an entirely wired enclosure with no trap or entrance (I have not yet allowed my birds liberty), and the hen house was constantly locked and the key in my own possession.

Each egg was hatched about eighteen complete days after it was laid. The two last-hatched birds (very small) did not live more than five or six days, but they looked healthy, and no doubt would have lived had they been transferred to another mother. One of the other young birds has since died one cold night, but seemed healthy. The largest of the four is now strong and healthy and half fledged. Of the parent birds the cock is a Blue Chequer with white flights and tail, the hen Blue with bars like a Blue Rock. The Pigeons are from the loft of Col. Hassard, R.E.—AN OLD SUBSCRIBER.

VARIETIES.

THE Rev. S. A. Brennan writes to us as follows on Gapes in Ducks:—"It may interest some of your readers to know that Ducks are liable to gapes, as a brood brought out in the autumn was seized with them. I never heard or read of an instance before."

—SALE OF PIGEONS.—The late Mr. Henning's famous stud of Short-faced Tumblers was sold by Mr. Stevens on Tuesday, the 22nd. There were about one hundred lots, and the sale realised between £300 and £400. The highest price given for an Almond was, we believe, £11. We saw two Black Mottles knocked down at ten guineas and eleven guineas each. The most remarkable feature of the sale was the large number of birds sold at over £4 each. Altogether it was one of the most remarkable sales we can recollect.

—ACCORDING to the *American Cultivator*, an association is formed to supply the city of Syracuse with pure milk. Each shareholder is a milk-producer, who contributes his own milk by delivery to the Company, each can being tested; and since the name of the man who contributes the milk is on every can, the Company is enabled to trace any deficiency in quality. The basis upon which these producers have associated themselves is that each cow will give six quarts of milk per day for 365 days in the year. That is the average taken the year through. The highest average is 3766 quarts per cow, the lowest 1843 quarts. Ten cows gave 3766 quarts each. The owner of these ten cows supports them on less than an acre each. Holstein and Ayrshire cows are generally preferred for crossing with selected cows of common breed. Corn meal is found most valuable to sustain the yield of milk during the winter.

—WRITING on the subject of feeding dairy cows, a correspondent informs us that Mr. Horsfall, the celebrated dairy authority, feeds his herds as follows:—Each cow receives 9 lbs. of hay, 6 lbs. of rape cake, 1 lb. each of malt comings and bran, with 28 lbs. of roots or cabbage. The food (except roots and hay) is given in a mixed cooked state and whilst warm. In addition to this food a cow in full milk receives 2 lbs. of beanmeal daily, and cows not in full milking order smaller quantities of this article.

—AMERICA'S meat trade with England commenced in October, 1875, with 36,000 lbs., and increased until April, 1877, it had attained to 8,578,213 lbs. Taking both salt and fresh meat, the total weight of dead meat imported into the United Kingdom, most of which is of American production, now exceeds the estimated dead weight of all the live animals imported. In the first ten months of 1877 Great Britain received, principally from America, 88,582,480 lbs. of salted meats, and 100,984,128 lbs. of fresh meats; her imports of fresh meat during 1877 have increased no less than 130 per cent. over those of 1876. Sixty per cent. of the population of Great Britain are dependant on foreign food.

—BEES.—All the bees in the neighbourhood of Allan, Tyrone, have died from starvation, no honey having been gathered in the summer. Stocks that were strong and flying about in December have, even with feeding, all perished.

—MR. STRATTAN recently stated at a meeting of the Monmouthshire Chamber of Agriculture that if it had not been for the prodigious grain crop in America there would have been well nigh a famine in this land. Now there is plenty to be had—only pay for it; but the amount of money to be paid this year from this country for food for man and beast is something very alarming, and probably will not amount to much less than £100,000,000 sterling. If this country could produce enough for its own consumption, and if this vast sum of money could find its way into the British farmers' pockets, there could be no doubt that we should not be hearing such lamentable outcries at the stagnation of trade as are now throughout the length and breadth of the country.

—THE *Irish Farmers' Gazette* reports an outbreak of typhoid fever at Glasgow, which assumed the form of an epidemic, the origin of which has been directly traced to poisoned milk. The medical officer to the health committee made a report on the subject, in which, after giving details showing that the milk was charged with the pestilential elements necessary to reproduce the fever, he remarked that "no more conclusive experiment could have been planned than that which has been unintentionally carried out among the inhabitants of Glasgow and Hillhead." The public spend enormous sums to provide pure water and

adequate drainage. The law lays all kinds of restraints upon vendors of alcoholic liquors, and imposes heavy penalties upon those who sell bad meat. All this is done expressly in order to limit the range and destructiveness of zymotic diseases. Not only so, but milk-sellers themselves are for certain purposes brought under the special supervision of the law. They may be punished for adulterating their milk, or even for diluting it. While we do all this, it is hard to see what objection can be raised to the further extension of the principle, so as to cover the culpable carelessness by which scores of people may at any time lose their lives, or be saddled with permanent and incurable injuries to their constitution. It is high time that milkmen were licensed like publicans, and placed under strict supervision and inspection.

— AN American has written as follows on the care of dairy cows:—The want of proper food, with exposure during calving time and thereafter, will easily account for fully three-quarters of the diseases of the ordinary farm cows. During the season of giving milk there is a severe strain on the animal system. The whole economy of the animal is exerted in the production of milk. Instead of getting fat, the cow does well if she holds her own; indeed, there is now and then a cow that, however fed, cannot be made to gain flesh during the milking season. They "run to milk," and the more feed the more milk. Is it strange that a cow at the end of the milking season be weak and more susceptible to changes of weather and to disease than those which have not had this drain on the system? Yet when a cow becomes dry or nearly dry she is too often turned out in the yard or stalk field to shirk for herself, when perhaps the increasing demands of an unborn calf are taxing her energies to the utmost.

— A CROP of 300 bushels of potatoes per acre removes about 180 lbs. of mineral matters, of which about one-half consists of potash and one-ninth part of phosphoric acid. A mangrel crop, weighing 20 tons of roots per acre, removes from the soil (excluding the amount taken-up in foliage), from 300 to 380 lbs. of mineral matter, including from 100 to 140 lbs. of potash, and from 15 to 25 lbs. of phosphoric acid. Cereal crops remove only about 85 lbs. of mineral matter per acre, of which 10 or 12 lbs. consist of potash, and 14 or 15 lbs. of phosphoric acid.

— DESICCATED EGGS.—The perishable nature of eggs has naturally detracted from their value as a standard article of diet. But lately the process of crystallising has been resorted to, and by this process the natural egg is converted into a vitreous substance of a delicate amber tint, which retains its properties for years unimpaired in any climate. In this form eggs may be transported without injury either to the equator or the poles, and at any time can be restored to their original condition simply by adding the water which has been artificially taken away. The chief egg-desiccating companies are in St. Louis and New York. No salts or other extraneous matters are introduced in the process of crystallising, the product being simply a consolidated mixture of the yolk and albumen. Immense quantities of eggs are preserved in the spring of the year by liming. Thus treated they are good for every purpose except boiling. It is a common trick for some dealers to palm off eggs so treated as fresh, so that imposition is easily practised. In the desiccating process, however, the difference becomes apparent, as from four to five more limed eggs are required to make a pound of eggs crystallised than when the fresh eggs are used, and eggs in the least tainted will not crystallise at all.—(*Cincinnati Commercial*).

— MR. CRANE, an American pig breeder of great experience, prefers the Berkshire breed for the following reasons:—"Because it has more muscular power and vitality, is hardier and less liable to disease than any other, and will make more pounds from the same quantity of food. Because the sows have large litters, are excellent nurses, and the pigs are stronger and better able to care for themselves. Because its flesh is finer grained, tender, juicy, and very solid, and ready for market at from six to eighteen months old. Because it is altogether the best to cross upon common stock."

— NOT only does America export large quantities of beef to this country, but a steamer lately arrived at Liverpool having as a part of her cargo 3500 turkeys, 1310 geese, 950 pairs of ducks, and 1321 pairs of fowls. The same vessel brought 1000 barrels of American apples.

— THE following experiment, says the *Prairie Farmer*, will bring fresh to mind what many know as to the value of charcoal, not only when fattening turkeys but other fowls. It will also be found a good corrective when used occasionally in winter when the fowls are confined to their quarters. The experiment was as follows:—Four turkeys were confined in a pen and fed on meal, boiled potatoes, and oats. Four others of the same brood were also at the same time confined in another pen and fed daily on the same articles, but with a pint of very finely pulverised charcoal mixed with their food, mixed meal and boiled potatoes. They had also a plentiful supply of broken charcoal in their pen. The eight were killed on the same day, and there was a difference of

1½ lb. each in favour of the fowls which had been supplied with charcoal, they being much the fattest and the meat greatly superior in point of tenderness and flavour.

FOOD AND FEEDING.

"A CONSTANT READER" asks this question, "What is the best food for bees?" Doubtless he means artificial food. Honey pure and simple is the natural food of bees, and is therefore the most wholesome. The best artificial food is syrup made of sugar and water at the rate of 1 lb of good sugar to one pint of pure water. Some use a larger proportion of sugar to the water with a view to make the syrup better and sweeter for the bees, and some enlightened apirians say that one pint of water to a pound of sugar is too much, as it necessitates the bees to eliminate or throw off more moisture than is good for hives. We have never once seen nor found any injury to bees or combs from using syrup mixed at the rate of one pint of water to 1 lb. of sugar, and this is the mixture we have given to bees for many years. Last year we gave our bees more than half a ton of syrup to keep them alive and strong. Good sugar mixed at the rate now indicated is a very near approach to the natural food of bees both as to sweetness and thickness. The syrup naturally found in flowers is no sweeter or thicker than sugar and water mixed at the rate of 1 lb. to a pint. The readers of this Journal have been frequently told that both the syrup of flowers (natural food) and the syrup of sugar (artificial food) are chemically changed after they are carried into the hives. This chemical action eliminates much water, leaving both the natural and artificial food much thicker and sweeter than they were when first presented to the bees. All artificial syrup used for winter food should be boiled before it is given to the bees.

The facts we have now stated respecting the change that syrup undergoes in the hive help us to determine the best times for giving it to bees. Winter feeding should be avoided in a cold country like England. The artificial process of feeding bees should be completed in October. The bees are thus enabled to prepare their food for winter use and properly store and seal it up. Artificial feeding in winter is very unnatural, and is attended with many dangers. Such feeding may cause the bees to leave their hives in cold weather and be chilled to death outside, and it might stimulate the bees to commence breeding too soon. Brood requires water, prepared food, and heat, and in cold weather bees cannot do much for their young. They have enough to do to keep themselves warm enough to live. Hives that have been neglected in autumn should not of course be allowed to perish in winter for want of food. They should be taken into a warm room or hothouse and there fed with warm syrup, keeping the bees of course inside their hives.

"A CONSTANT READER's" hive which weighed 23 lbs. in September will probably require feeding next month. As his residence is in the south (Salisbury) he may safely begin to stimulate his bees by slow and gentle feeding by the middle of February. What is meant by gentle feeding? Giving a hive a small dose of syrup three times a week, say 1 lb. of sugar in a fortnight. This gentle spring feeding is a great encouragement and stimulus to bees, and costs very little. Let all bee-keepers look to their hives now and see that none be lost from want of food and attention.—A. PETTIGREW.

WINTERING BEES.

ON page 60 Mr. Pettigrew declares our little favourites must be kept warm; in short, are doomed to a life "of suffering during the winter months," "suffering" doubtless, but only at the hands of their ignorant possessors. But this is not the way your correspondent puts it. "Nature, in the case of animals of various kinds, covers them with hair, and wool, and feathers on the approach of cold weather. The All-wise Creator covers them with good warm coats." Overlooked in the great scheme of Nature, coatless, he proposes to supply the want as follows:—"If I were asked what covering I would prefer for a hive in winter I would say a large woolly sheep's skin turned inside out and tied closely round the hive." We had heard of the "warm" theory before, and of bee-keepers ignorant of the natural history of the bee transferring their hives to their greenhouses for the winter with most deplorable results. In your correspondent's case the warmth of the wool would at once greatly raise the internal temperature of the hive, and the dormancy of the bees would be destroyed. He stipulated the skin was to be tied "closely;" the closer the worse, the heated vapour finding no way of escape through the dry hard impervious skin. It mattered little whether the hive were of wood or the orthodox straw, would rapidly condense in all probability on its sides and combs, and the "suffering" consequently entailed on the little people through the damp and moulded combs must sooner or later inevitably as well as hermetically seal their fate.

If cold is so prejudicial to bees, how comes it that power is given them to resist the intense frosts of the fearful winters of

Russia and North America with impunity? and also with us, when they make their escape from their careless owners for the bee tree, the old church tower, or the house-top, bidding for ever adieu to the ill-ventilated, damp-soaked, old-carpeted, old-bagged, straw-dwelling vermin-secreters. According to the "warmth" theory coatless and unprotected at the approach of cold weather the bees must inevitably perish; but no, they inhale with delight the pure fresh air, on the occasional mild winter day feast on their treasured store, rush forth, and disport in the bright sunshine happy as children on a holiday, and on the return of winter's stormiest icy blast they creep all the closer together, the rocking and creaking of the old tree singing the lullaby to their more thorough and snug dormancy. Having served my apprenticeship to bee-keeping amongst the colonies, which were long located in our house roof here, it was long a puzzle why such vagabond swarms preferred settling with us as well as in neighbours' roofs at the very coldest or north aspect, till at last the truth forced itself upon me that it was there they enjoyed the most thorough and undisturbed dormancy with the consequent minimum consumption of store.

The great enemy the bee-master has to contend against is not cold but damp, external as well as internal. I thoroughly agree with your excellent contributor "B. & W.," that it matters comparatively little of what material a hive walls are formed. Straw absorbs, retains, and decomposes from damp much more readily than wood. The secret lies in the top; heated air ascends, and if no provision is made for its escape is bound to condense and trickle down. To illustrate this, eighteen years ago on the memorable morning of 24th of December, 1860, the mercury in the tube of a thermometer inside a hive shrank to 7°, or 25° below the freezing point, and yet that stock survived and came through in fine order, although the four walls were formed of doubled glass secured by wooden corners. I ascribed its preservation to the thorough ventilation afforded by slides of Indian matting running in its bar grooves on the top. That useful material for wintering hive tops I was privileged to recommend first in this Journal before its adoption in America.

My own bees are kept and wintered in high wooden loose outside covers, the body in one piece, top moveable, and covered with zinc, ample facilities for ventilation, and well painted, side entrances to hives closed in winter, central open for free circulation of air. I use no packing stuffs whatever for wintering, being particular that nothing rests on hive tops to prevent the escape of all ascending vapours through the thin slack moveable slides working in the frame bars. In my few straw hives similarly externally protected I find the firm wrought cane flat top being in a piece does not offer the same facility for escape of vapours, and consequently as a rule in the spring examination are not quite so dry internally as are my Stewarton wooden colonies.

In past times in the south the clumsy thick wooden crown boards used on earlier wooden hives did much to impede their proper ventilation during the winter months. Mr. Abbott has done good service to the cause of apiculture by recommending their removal entirely during the dormant season and substituting a "quilt;" of course care must be taken in its construction. A thick wet blanket as well as a central draught are two things to be guarded against in wintering bees.—A. BENFREW'SHIRE BEE-KEEPER.

OUR LETTER BOX.

ACCOUNT BOOK (G. H. W.).—We believe it is not now published.

FEEDING BRAHMAS, COCHINS, AND HOUDANS (B. B.).—We are sorry we are compelled to condemn the dietary of your fowls. We believe it to be the cause that you have no eggs. The breeds are all hardy and good. A large proportion are too young to lay regularly, but some of them should. Cochins and Brahmas should lay at six months old, but you should hatch them earlier. If your birds were April or May pullets they would now be laying if their food were better. Dried potatoes are bad food; they give diseased livers, and they are not good enough. Turnips are worse. Bran and half-ground Indian corn are poor food, especially the former; in fact, all your food is deficient in nutriment and the material for bone. We do not believe you are a savior by these substitutes for proper food. At this time of year, when the grass run yields little in the way of support, your fowls will want more food than in the summer. They have to endure long cold nights. The days are short and chilly. You feed your fowls as if you fed yourself, when the ground is covered with snow and the thermometer is falling daily, on a small portion of cold meat, with cucumbers, radishes, and salads. We believe we can put you on a better plan, and we hope it will not be found more expensive. Let the morning meal be of good ground oats or barley-meal soaked with water; mid-day give whole corn, maize, or barley, the latter preferable; afternoon same as morning. There should be no deviation from this, except when the house scraps and table-cloth sweepings make enough for the mid-day meal. This should be a substitute for it, and not an addition to it. Nothing more is required, and all deviations are drawbacks. The true guide in feeding is to follow Nature as closely as possible. Fowls do not find cayenne pepper in the fields. All these contrivances are injurious. You do not state the width of your grass run, but taking it at 1000 yards in length and 30 in width you may safely keep fifty fowls. We do not say you may not keep more, but you must recollect when you have chickens you will have to devote a space to them, and it is always better to be under than over-taxed.

SELECTING A BREED OF FOWLS (W. W.).—Before deciding on any breed it is necessary to first consult the conveniences for keeping it, next that

which it is proposed to accomplish. We always think crossbreeds are a mistake unless a man thinks they will last his time, and after him "the deluge." If he wishes his fowls to go first they will make nothing because they are cross-bred. Spanish have always been called the aristocratic breed, and they deserve the name. They have the Castilian bearing, and couple it with beauty—black plumage, red combs, and white faces. They are not destitute of homely merits. They lay a large number of very large eggs. They may be hard run by the Crève-Cœur, but in the day when eggs are sold as they should be, by weight, then we believe the Spanish will be the best layers. You cannot do better than keep to them if you will submit to the slight inconvenience of having to procure sitting hens. They do not sit. The Spanish cock should be tall, upstanding, have a perfectly white face, the smoother the better, long legs, and perfectly black plumage; the comb should be quite upright, straight, and as stiff as a cockade. The hen should have the same qualities, but her comb should fall over. In both sexes the legs should be blue. They bear confinement, but do better at liberty.

SIZE OF POULTRY-HOUSE (Yorkshireman).—A wooden house is all that is necessary for any poultry. If you keep fowls by hundreds you should have several houses. There are few places in the country that are not already provided with them. Old cow-stalls, calf-pens, barns, cart-houses, wood-houses, lean-to's—anything will do. To roost a hundred and keep them healthy you want 30 feet by 25.

RING DOVE.—T. Byrne asks what is the usual lifetime of this bird.

ATTACHING PIGEONS TO THEIR HOME (L. B.).—Give them salt-cat. It is composed of about equal quantities of clean unctuous loam, such as brick-makers use, coarse gritty sand or fine gravel, in which the grains are about the size of pins' heads, and old mortar, to this add a small quantity of large-grained salt. Some persons, to make it more attractive, add aromatic seeds. The whole should be mixed-up into the consistency of mortar and placed in a crook, the sides of which are perforated with many holes large enough to admit the Pigeons' heads, and covered with a lid to keep off the weather.

REMARKS.

23rd.—Bright fine morning, windy, shower at 3.30 P.M.; starlight night.
24th.—Fine morning, with sunshine; overcast in afternoon.
25th.—Great gust of wind at 7.45 A.M., snow showers at 7.40 A.M. and 10 A.M., sunny afternoon; very cold high wind.
26th.—Very bright fine day; starlight night.
27th.—Foggy morning, dull all day; wet afternoon and evening.
28th.—Damp rainy morning, very dark at 0.30 P.M., rain till 3.30, then a little sunshine; cold starlight night.
29th.—Bright sunny morning; misty in afternoon.
Prevailing wind northerly, and temperature therefore more seasonable than in previous weeks.—G. J. SYMONS.

COVENT GARDEN MARKET.—JANUARY 30.

SMALL consignments of late Apples still reach us, otherwise our home market is almost bare. Foreign goods consist of Pears from California, and Pears, Apples, Salading, and Asparagus from France.

From observations taken near London during forty-three years, the average day temperature of the week is 45.0°; and its night temperature 30.9°.

TUBEROUS-ROOTED BEGONIAS.

PRIOR to the introduction by the Messrs. Veitch of *Begonias boliviensis*, Pearcei, Veitchii, and *rosæflora*, the material for effecting improvement in this class of plants was extremely limited. *B. discolor* (Evansiana) was a popular window plant to my recollection over thirty years ago; indeed it was the only one cultivated for sale in 1827, and Masters of Canterbury in 1831 only enumerates it and *B. argyrostigma*. *B. octopetala*, though introduced in 1835, never came into general cultivation, and is now taking its place in this beautiful class as a new variety, rather species, whereas it appears to have been the first of the introductions from the Andes.

Before the introduction of the first-named four no effort had been made to improve the tuberous-rooted section, though some attention had been given to the type which embraces *B. Ingrami*, *B. Saundersi* (an improved *B. semperflorens*), and *B. Digswelliana*; there being only one hybrid of the creeping rhizome section—viz., *B. hydrocotylifolia hybrida*; and singular enough only one of the semi-bulbous or caulescent section—namely, *B. Weltoniensis*, raised by Major T. Clarke. *B. Weltoniensis*, a cross, I believe, between the caulescent *B. Dregei* (*parviflora*) from the Cape of Good Hope and some pink-flowered species, has become quite as popular a window plant as *B. Evansiana*, and there is no doubt that when the hybrids of the *B. boliviensis* and Veitchii section become better known they will be equally if not more popular for that purpose. The horticultural world is greatly enriched by the possession of this beautiful and useful class of plants.

B. Pearcei sent out in 1866 is very beautiful in foliage, "dark velvety green, traversed by pale straw-coloured veins and the under side of a dull red colour." The flowers are large, borne on slender stems, bright yellow; with a tinge of pink at the base of the segments. It is a fine decorative plant, and in a stove temperature will form in early summer a fine table plant, blooming for many months. It requires a warm greenhouse. *B. boliviensis* attains 2 feet in height; foliage light green; flowers red, very freely produced, generally in pairs, sometimes in trebles. *B. Veitchii*, the most valuable on account of its hardiness; flowers large, vermilion or cinnabar red. *B. rosæflora*, stemless, flowers borne upon erect scapes, large bright rose. Those are the parents of the following very beautiful kinds sent out by Messrs. Veitch:—

B. Sedeni, "a cross between an unnamed species and *B. boliviensis*," having the habit of the latter, with larger leaves; flowers magenta crimson. *B. Chelsoni*, between *B. boliviensis* and *B. Sedeni*, free in growth; flowers salmon orange, and blooms for several months. *B. intermedia*, a cross between *B. Veitchii* and *B. boliviensis*, of erect free branching habit, about 18 inches in height; leaves like *B. Veitchii*, but toothed like *B. boliviensis*; flowers large, very freely produced, rich vermilion red. *B. Stella*, large rosy crimson. *B. Vesuvius*, one of the finest, orange scarlet. *B. Model*, a real beauty as might be anticipated by "inter-

crossing *B. Pearci*, *B. Veitchii*, and *B. Sedeni*," finely-formed flowers, rosy blush. *B. Excelsior*, "a cross between *B. Chelsoni* and *B. cinnabarina*." This blooms as freely as *B. Chelsoni*, flowers light orange, and large. *B. Acme*, robust habit, large orange pink flowers. *B. Kallista*, more floriferous than *Stella*, and deeper in colour. *B. Emperor*, vigorous habit, free-flowering, large brilliant orange-scarlet flowers in large clusters.

In addition to the above we have the following, which are chiefly of continental origin:—Charles Raes, an improved *Sedeni*; Charles Van Eckhaute, white or delicate pink and late; Dr. Masters, carmine crimson; James Backhouse, scarlet or coral red, spreading habit; Paul Masurel, orange scarlet; Bayard, orange; Reine de Bougival, cream; Sunrise, rosy scarlet; Aurora, salmon yellow; Étna, scarlet; *Rosæflora superba*, rose; and Agate, vermilion; also the doubles, Lemoinei, orange and vermilion; Gloire de Nancy, shining vermilion, of erect branching habit, and very free-flowering; Éclatant, pale rose, dwarf compact habit; President Burella, strong grower, deep vermilion; W. E. Gumblerton, pale salmon; and Van Houtte, deep salmon. *B. Froebelii*, scarlet; and *B. octopetala*, large flowers, white, with the reverse of the petals pink, late-flowering, also deserve mention and cultivation, as very attractive species.

It is being somewhat generally asserted that cool treatment only is required for this class of plants, to which I do not demur if the aim be flowers in the open ground, window, greenhouse, or conservatory very late in the season; but those contenting themselves with a display in late summer lose much of the beauty the plants may be made to afford by starting them in a forcing house. Plants so treated flower in May and June, and by keeping them rather dry, yet not so dry as to induce complete rest, the same plants will afford a second bloom little inferior to the first in late summer and autumn. This forcing the plants bear well, particularly *B. Pearcei*, *Chelsoni*, *Model*, *Vesuvius*, *Excelsior*, and *Perle*, the first and last having beautiful foliage as well as handsome flowers.

For this purpose the tubers should be potted early in February, removing all the soil that comes away freely, without, however, stripping them quite bare of the fibres that immediately surround the corms. Pots twice the diameter of the tubers are sufficiently large. The tubers should only be slightly covered with soil. A suitable compost is three parts of turfy loam with one part of leaf soil or old cow dung, and a part of sandy peat, and a sixth of sand. Good drainage must be given, and the soil made moderately firm. Place them on shelves near the glass in a house with a temperature of 65° to 60° at night, or a few degrees lower in severe weather, and 70° to 75° by day, with an increase from sun heat. Apply water very carefully, giving just sufficient to keep the soil moist until growth is made; indeed avoid overwatering at any time, it requiring to be most liberal when the plants are in free growth and coming into flower, at which time weak liquid manure may be given. When the plants have filled the pots with roots shift them into others about 4 inches larger in diameter, and afford plenty of room and light, sprinkling overhead twice a-day, for they like a moist atmosphere, but not a

confined one. When in flower and placed in a warm greenhouse or conservatory the sprinkling should be discontinued, and rather freer watering given. After flowering they are to be dried-off gradually, the pots being placed on damp soil or a moist bottom in a cool house, where they remain until again required; but if wanted to flower again in late summer cut them back and thin-out the flowered parts, returning them to a warm moist house, and they will give a second bloom little inferior to the first. This may be considered an exhausting process, but B. Pearce at least, which I have so treated for seven years, shows no signs of debility.

For greenhouse culture an early bloom may be had by potting the corms early in March and bringing them on slowly in a temperature of 50° to 55° from fire heat, an intermediate house answering perfectly, removing them to the greenhouse or conservatory when in flower; but for simple greenhouse culture they need not be potted until they begin to grow, then reducing the ball, retaining the fibrous roots and reducing the size of the pot considerably, shifting into larger pots as required, giving the last shift when the plants show for flowering. After that is past, which lasts eight to twelve weeks, keep the soil sufficiently moist to maintain the foliage fresh. When indications of ripening set in gradually cease watering. The pots may be wintered on the soil alongside the pathway in a cool greenhouse, plunged in ashes in any place but a dry one, provided they are safe from frost. The tubers must never be kept dust-dry, or they lose their vitality. This over-dryness is not confined to tubers already in hand; it occurs with those purchased. I know many last season had a supply of dry tubers, a large per-centage of which refused to grow; I had some of B. Froebeli which were in that condition, and shall reject such supplies in future.

Begonias of this class do not like a dry atmosphere; they will live in one, but it only results in enfeebled growth and poor impoverished flowers. They do not like draughts or sudden changes of temperature; therefore those growing them as window plants will do well to open the upper part of the window for ventilation preferably to the lower, and not much of either. I saw such a display of Begonias last summer in a miner's window as surprised me, accustomed as I am to plants.

The great merits of these plants are as bedders. In my estimation they are more beautiful than Zonal Pelargoniums and more enduring. Pelargoniums when at their best have every particle of beauty washed away by a few days of wet weather. Not so Begonias; they revel in moisture like all sub-alpines—percolating moisture secured by thorough drainage. Those, therefore, intending their culture (and it will become general) will do well to provide thorough drainage and a sheltered situation, as the plants being succulent cannot stand twisting currents of air and cold positions. They prefer a vegetable soil, and do well in the wide interstices of rock-work holding a goodly amount of compost, in which they may remain permanently, having a mulch over them in winter of cocoa-nut fibre refuse 3 or 4 inches thick.

For summer bedding pot the corms in March, plunging the pots in ashes in a cold frame, keeping close and protecting from frost until growth takes place, then admit air moderately, sprinkling overhead in the afternoon of bright days, closing early. By the middle of June they will be in good growth, and being hardened off should then be planted out. In cold localities I advise their being planted in borders along the sides of plant houses with a south exposure, in which with a covering of cocoa-nut fibre refuse 3 inches thick they will no doubt prove hardy. In wet and cold soils the roots may be lifted after the first frost, and be laid in a shed for a few days to dry, and having most of the soil removed be stored away like Dahlia tubers in sand in a cool place safe from frost, where they may remain until potting time in spring. But an amateur tells me all this "potting and bother" is quite unnecessary, as the Begonias only require the treatment he gives his Dahlias—viz., planting the roots in April 3 inches deep, inverting a flower pot over them until the growth cracks the soil, then removing the flower pot every fine day and night, covering the plants only when there are signs of frost, and "you know I have the best display of flowers of those plants until frost of anybody hereabouts."

A few hints as to propagation. Take cuttings of the young growths when 3 inches in length or with two joints and the growing point, insert them singly in small pots and place in gentle heat, keeping close and moist, but avoid over-watering. Shift them into larger pots when rooted, and being established and hardened-off remove them to a greenhouse, and they will flower and form good tubers by the autumn.

Seeds also are resorted to. It is an interesting mode of propagation. I drain a pot or pan—the former half, the latter a third its depth, with potsherds, place some rough compost over the drainage, fill to the rim with soil, having the surface very fine and even, and give a good watering. The seed is then cast on the surface, and a little, very little, silver sand is sprinkled over it. The pot or pan is placed in a Cucurbit frame and shaded from sun to prevent the necessity for watering; but if the surface be inclined to dryness water must be given very gently through a fine rose. The seedlings are potted off singly when they can be handled, returned to the frame, shaded, and kept moist. When established they are removed to a shelf in a warm house, and have a shift into a larger-sized pot. They flower in late summer.—A LOVER OF BEGONIAS.

VEGETABLE CULTURE.

CHAPTER VI.—BRUSSELS SPROUTS.

THIS vegetable takes its name from Brussels, where it was, and I believe still is, very extensively cultivated. It is one of the oldest inmates of our kitchen gardens, records being made of it in the early part of the thirteenth century. Although the Brussels Sprout is considered an indispensable vegetable in large gardens, it is frequently not grown at all in small gardens, which should not be the case, as few vegetables are more acceptable or can be grown more remuneratively for autumn and winter supply.

In exceptional instances the seed is sown in autumn to furnish young plants for transplanting from the seed bed early in spring; but I have never found this plan answer better than sowing in spring, and we always adopt this system now with the best results. When the Sprouts are wanted, say in September, a pinch of seed should be sown in a box the first or second week in February. A box 2 feet square will produce many plants. The seed may be started in gentle heat, but as soon as the young plants are 2 inches high the box should be placed in a cold frame and remain there until the plants can be fully exposed, and when quite hardy, they may be dibbled 4 inches apart into some good soil in the open air. With good treatment these plants will be ready for transferring to their bearing quarters in April. With this, as with all other vegetable plants raised artificially, it is of the utmost importance that the young plants are never allowed to be drawn up long and spindly by being grown too closely together or any other cause. It may be remarked that those who do not possess frames or houses in which to start early vegetables will find the different kinds of plant protectors now so much advertised answer the purpose very well.

The first sowing of Brussels Sprouts should be made in the open ground about the middle of March. The situation of the seed bed should be open and the soil free and rich. It is scarcely necessary to give particulars on this head for every crop, because the best way is to select and set apart a small piece of suitable ground on which all the seeds from which plants are required for transplanting should be raised. Our piece of ground for this purpose is about 12 yards across and double that in length. Supposing we sow at the same time such seeds as Cauliflower, Broccoli, Brussels Sprouts, Cabbage, Savoy, &c., a bed 3 or 4 feet wide is marked off across the narrow way of the piece, and this long bed is subdivided into a number of small beds, generally about 2 yards long. A different vegetable or another variety of the same vegetable is sown on each of these, and beds of successional sowings follow one another.

In sowing Brussels Sprouts the surface of the bed should be broken moderately fine, and after the seed is sown cover it with about half an inch of soil, and beat it down with the back of the spade. The means previously advised to prevent the birds from destroying the seed should be attended to in the case of this and all other seeds of this tribe. The plants from this first sowing will be ready for transplanting in May. When the plants come up very close together the largest of them may be drawn out and be planted first, and the smaller being left for two or three weeks longer to form a succession. The seed to supply the latest plants should be sown about the end of April. It must be treated in all respects like the first; but if the soil is very dry when the plants are quite young they will be much benefited by watering, and this should be repeated when necessary. Plants from this sowing may frequently be planted on ground recently cleared of early Potatoes. In such a case the ground need not be dug but

merely levelled; but should the young plants become crowded before the ground is ready for them, the largest of them should be drawn out and planted again 4 or 5 inches apart. In lifting young plants when the soil is very dry the ground should be thoroughly saturated with water the night previous to removing them from the seed bed. When the young plants have been brought to a transferable size their after-cultivation is simple enough. They succeed best in a moderately firm soil not overful of manure, as a firm growth is more desirable than a large quantity of tender leaves. We never plant further apart than 2 feet. The plants grow about 18 inches high, and are always surrounded from top to bottom with dozens of Sprouts as close as they can grow. When the latest plants cannot be lifted with balls they should be watered twice or three times a week after planting them in hot weather until they begin growing. Snails are ready enough to destroy the plants if not looked after. The Dutch hoe must be run through the ground frequently until the plants are ready for earthing-up, when the soil should be drawn firmly to each plant. In autumn the decaying leaves should be gathered frequently, as they fall down on the Sprouts and cause them to decay. The Sprouts should not be used until they have folded quite hard, and they should all be gathered before they begin to open again, which they ultimately do. Medium-sized Sprouts are preferable to very large ones. The best varieties of the Brussels Sprout are Dalmeny, Dalkeith, and Roscherry. The "Giant" Sprouts of the leading seedsmen are all good, and very useful are the Albert Sprouts.—A KITCHEN GARDENER.

DUKE OF BUCCLEUCH GRAPE.

We have not heard quite so much about the character of this Grape as we have of its sister variety Golden Champion. I was pleased to read that your correspondent "COLUMBUS" has succeeded in growing "The Duke" so as to give so much satisfaction to his employer. I do hope that he will also succeed in growing it equally well when he has planted a house of this sort alone. I would advise him to plant a few Black Hamburgs along with the Duke of Buccleuch in case this variety should not succeed so well as he expects. I believe this variety was sent to Covent Garden before it was sent out. But is it sent there or to any other market in quantity now? When Golden Champion was sent out it was thought by its raiser and others that it would be a white companion to Black Hamburg, with a constitution like that sort, and requiring no more care in its culture. I fancy the same expectations were raised in respect of Duke of Buccleuch. Now I venture to say, that if the gardeners of England and Scotland who have grown this Grape were invited to give their opinion as to whether these expectations have been realised, very few would say they were. That it is a noble Grape when well grown no one will deny, but I believe gardeners who have not been able to grow this Grape satisfactorily are not unlikely to incur the displeasure of their employers when they read that the "Grape will succeed when it has the same chance as well-cultivated Black Hamburgs."

Now I have given it the same chance as well-cultivated Black Hamburgs, and have grown it alongside Buckland Sweetwater. I find that Black Hamburg and Buckland Sweetwater succeed well and finish off good crops of excellent Grapes annually. I was anxious to grow Duke of Buccleuch in this house, thinking it would be better than Buckland Sweetwater for exhibition, but in that I have been disappointed. The berries spot, crack, and decay before they are quite ripe, and the atmosphere of the house has been kept drier than I like purposely to suit His Grace. The Vine in question was inarched on a free-growing Black Hamburg. I did not try it in any other house, thinking it best to see how it behaved first, and did not think it wise to try it further. I grew Golden Champion in three houses, ripening it at different times, and it only did fairly well in one house, so I have cut it out from the other two. My own impression about the Grape is, that it can only be grown well if the utmost care is taken. I trust your correspondent is aware that head gardeners cannot be in their vineries night and day; in most cases they have to trust the work almost entirely to young men of limited experience, and they have sometimes to change the person in charge when the fruit is in course of development.

Your correspondent says the Grape will not succeed "under a system of steaming, damping, and syringing, now abandoned by all who produce good Black Hamburgs." Is your correspondent prepared to reiterate this statement, and to say that

he does not produce any moisture in his vineries from evaporation? That is what he does say, and as a Grape-grower of considerable experience I must say the system is quite new to me. Perhaps I should not have noticed your correspondent's letter if he had not stated that the old system of growing Grapes had been abandoned by all good growers for the new one of no atmospheric moisture at all.—J. DOUGLAS.

JUDGING ROSES.

I HAVE read with much interest the various letters in the Journal on judging Roses, and have been a little surprised at the variety of opinion evinced; but no one's ideas strike me with the amazement that my good friend Mr. Curtis's do. I am exceedingly grieved to have to differ with him on any point of Rose culture, but as this is a matter of the greatest moment to Rose exhibitors I cannot resist giving my opinion on the matter. Mr. Curtis's idea is to my mind simply impracticable. It is all very well in theory, but in practice impossible. In the first place, Where are all the judges to come from? The leading exhibitors and say half a dozen outsiders will furnish twelve judges, and that is all that is or can be required.

At our great meeting at St. James's Hall there was no delay in the judging, and there were I believe only twelve judges, or at most fifteen; six for the nurserymen, three for the amateurs, and three for the open classes. I am not sure whether those who judged the open classes also judged the small amateur classes, such as twelve and six varieties, but I think they did. Nothing could have been more successful than the plan then carried out, and I do not see what case has been shown to induce us to alter it. The system of cards alluded to by Mr. Curtis is the most bewildering one I have ever heard of, and the whole plan would take far more time than could possibly be allotted to it.

What system can be better than that usually adopted at exhibitions? There are three judges to each great division of the schedule. Say we are judging a nurseryman's seventy-two. We begin by counting the good blooms. Each judge takes it in turn to count, the other two judges stand behind him and stop him when they do not agree. When there is a difference of opinion, if two of the judges say the bloom is a good one it is counted, if only one it is not. Then we go to the next stand, marking down on a piece of paper the numbers. Next we count the bad blooms, and the work is accomplished. Generally the first prize is a very simple matter; it is when we come to the second, third, and fourth that the tug of war commences. After we have counted both the good and bad, and the stands are so even that we cannot separate them, then we must look to what I may call the accidentals of the stands. One is more even, another has fresher blooms, or another has greater variety; all these are taken into consideration. Oftentimes all the boxes of blooms are placed together, and are viewed at close quarters and from a distance, and the result is that I have never heard any dissatisfaction expressed (except on one occasion) by the great nurserymen after such an exhaustive judgment. But here no doubt someone will say, "My dear sir, you are begging the question, you are arguing on a false issue. It is not the plan of judging that we are so much exercised upon, but the canons or rules. You say we count the good or bad blooms; all very well, but we want to know what are good blooms, and by what rules you determine such a momentous issue." Well, I have no objection to show my hand and to state boldly in print what I consider constitutes a good bloom, fully conscious though I am that I am laying myself open to criticism.

First, then, I and the judges with whom I have most often acted consider form as the great desideratum of a Rose. Not size—far from it, but form, or if you want even a plainer word, shape. Every Rose to be accounted good must have this; next colour, then freshness, next substance, and lastly size.

If I am asked what I mean by form, I would say symmetry. It may be globular, or cupped, or even expanded, but it must be symmetrical. Its eyes must not be in one corner for instance, or it must not have a bunch, or tie, or knot, as if something had disagreed with it in childhood. It does not follow that it must be large. Blooms of Duke of Wellington are never large, and yet there are few judges who would not count them good if they possessed the other qualifications.

The colour must be fresh and bright; it need not, for it rarely is, so dazzlingly vivid as the blooms which Mr. Baker brings up to town, for the secret of obtaining that colour is only known to the inhabitants of that terrestrial paradise Heavitree.

"They do say, sir," said my man to me when discussing the question how he obtained that colour, "that he gives them 'ops," and I believe no better (?) solution than this has yet been found.

The blooms must be even. We must not have a gigantic Paul Neyron that, to use an American expression, appears to "have been under a quartz crusher and then boiled for a month," and next to it a puny bloom of Comtesse de Chabillant; and each bloom must present itself to our eyes under the most favourable circumstances. It must be well set up, have its proper amount of foliage, and be a good specimen of the variety.

I shall be interested to see what rules are laid down by the Executive Committee of the National Rose Society, which I suppose will in due course be laid before the General Committee; but I shall be very much mistaken if some such table of virtues as that I have tried to describe is not adopted.

Where and where only competition is so close that we cannot otherwise decide, the system of giving points is no doubt the best plan that can be adopted; but it is a very tedious one, and should only be resorted to as a *Deus ex machina*. Three judges discuss each Rose, giving three points to a very good one, two to a good one, and one to a moderate one. It is evident that a discussion may be raised on each Rose, so that such a system should only be employed when all others fail.

I have written these notes in the hope that they will provoke discussion, and that they will afford a basis upon which Rose-growers may express their opinions. I am aware that there is a feeling abroad that some rules as to judging are to be desired, but I must say such an idea is not shared in by a—WYLD SAVAGE.

EVERY rosarian will, I think, agree with your able correspondent "D., Deal," that it would be very desirable that some broad general rules for judging should if possible be laid down by the National Rose Society. But how difficult a task it would be to frame a code of rules that would fall in, even approximately, with the views of say a dozen of the leading Rose judges? There would be, I suspect, a good many dissentient voices to his proposal, for instance, that no points should be reckoned in favour of Teas because they are Teas. I venture to differ entirely with "D., Deal," on this point. To my mind the presence of a few charming Teas in a box suggests at once that it belongs to a real lover of the Rose and not to a mere exhibitor (and, believe me, there are pot-hunters even in the Rose world), as they are evidences of a greater amount of skill, care, and attention than is required to produce correspondingly good blooms of most of the Hybrid Perpetuals, and in my opinion they deserve a greater number of points in consequence. It is true that, as your correspondent says, the growers in Devonshire and Cornwall have an advantage in this respect over the rosarian in sterner climates; but surely no rules could be framed whereby the advantages which soil and climate must necessarily give to the growers in the more favoured localities could possibly be neutralised, nor do I think it desirable that they should be.

As regards the freshness of the blooms. It is greatly to the credit of exhibitors who have to bring their flowers on perhaps a hot July night two hundred miles, and to shift them about from rail to cab, &c., if they can stage a box of Roses in the perfect freshness of their beauty; but if several of the blooms, after having borne the heat and burden of the night, are a wee bit *passé* it would be a very difficult thing to have to make an allowance for them on account of the journey they have undergone; and unless this were done, if colour be a point in a Rose, the exhibitor who is on the spot must, from the superior freshness of his blooms—like he who is in the best climate or on the richest soil—inevitably have a decided advantage over him who competes under less favourable circumstances; and I think it would be found hopelessly impossible to draw up any code of rules which would place all the exhibitors on an equal footing. The merit of a first prize is in proportion to the difficulties to be overcome in gaining it. A. G. S., *Irnham*.

CAULIFLOWER CULTURE.

LAST spring, owing to the excessive wet of the winter months, Cauliflower plants were extremely scarce in this locality. In conversation with two or three more gardeners interested in the subject Mr. Brunton, gardener at Gilmerton near Drem, stated that he annually raised thousands of plants in cold frames,

the seed being sown in October, and at the usual planting-out time the plants were superior to plants raised by other means. Last autumn, owing to the extreme rainfall and partly to the seed not being good, our out-of-door sowing was next to a failure, and in thinking over the best means of making good the deficiency the conversation above noted came to mind, and late in October a sowing of Cauliflowers and Brussels Sprouts was made, and the plants have every appearance at the present time of being very valuable. In the course of the same conversation another gardener remarked that he had kept Cauliflowers for a considerable time by cutting the heads off with a short piece of stalk attached, and which were planted in sand in a cool moist shed. I have not tried this plan, and now-a-days when such good late sorts as Autumn Giant Cauliflower and Self-protecting Broccoli are to be had it is not of so much consequence. I may mention that I have not had an Autumn Giant to cut in the past season, and a large grower close by has the same tale to tell of it. May the plants be expected to form heads this summer?

I have tried covering the seed beds with mats, as recommended at page 61, and find it a sure means of raising seedlings during hot weather; the mats are also a thorough protector from birds. In our light soil I prefer planting before the seedlings have attained to half the size recommended by "A KITCHEN GARDENER." A row of Lettuce between each two rows of Cauliflower, Brussels Sprouts, and Broccoli I find of service to preserve the permanent plantings from the ravages of pigeons, and in heavy soils where slugs are often destructive I think the Lettuces do much good in attracting them from the main crop. The Cauliflower is such a highly esteemed vegetable that I am sure the contributor of the practical notes on its culture will excuse me for making these supplementary remarks.—R. P. BROTHERSTON, *Tynningham*.

THE RASPBERRY.

I WISH to say a few words in regard to this fruit, because I scarcely think it has received sufficient attention at the hands of the horticulturist. Its varieties are not many, even when all are diligently put down, as in "The Fruit Manual," and even there, where their numbers are printed every one, they barely fill four pages, whereas the numbers of the more aristocratic Strawberry fill thirteen pages. Of course I do not say that the Raspberry is equal to the Strawberry. Art has done more for the latter, and the grander kinds have departed further from the original type. Then, the Strawberry can easily from its habit be forced, but with the Raspberry this is impossible. Allowing all this—allowing that no dish of Raspberries can equal in appearance one of Strawberries—still I think the Raspberry has not had sufficient pains bestowed upon it. Too often any out-of-the-way corner was and is deemed good enough for its growth, and the wrong system of growing is pursued. Thus the canes, too many in number, were closely twisted together, many fruiting buds being thus rubbed-off or crushed, also no light let into the canes, and worst of all the owner or jobbing gardener diligently once a year dug the ground deeply and brought to the surface and barrowed-off to the refuse heap great quantities of roots; and the old stools were left standing high up like islands, with no roots save those immediately under them. Then there is the blackbird-and-thrush-encouraging plan of growth—viz., bending the canes into arches. This is a plan so kind to the birds, to which it gives a series of pleasant perches whereon to sit and eat and enjoy the fruit. An old-blackbird might probably be heard in bird language (not understood by us poor human beings), might, I say, be heard telling the younger generations that "though man is bad, and the man-gardener the worst, yet something may be said for even that hard-hearted gun-discharging animal, for he does leave us the Raspberries and kindly bends them into perches for us to swing on, and sing on, and eat and be thankful."

So much for the wrong ways of growing this fruit. Now for the only right one, and, by the way, in this world in everything there is only one right way, and that is the best way. Some ways may be better, but why not always adopt the best? I have before now been very angry with doctors, whom as a country parson I often meet in a sick room, who are accustomed to say, "Well, I have tried so-and-so" (doctors are always confidential to me), "and now I am going to try so-and-so with your poor friend upstairs, and if that does not answer why I must try so-and-so, and that I am sure will." I always add, "Why don't you try the infallible cure at once, and why didn't you do so at first." The doctor looks puzzled, searches for an

answer, does not find one, and wishes me a very good morning. So I say, Find out the right way—the one right way, and the best way surely at the same time.

As to Raspberries, I have seen people train them fan-wise to sticks. I have seen others have a stake at each end of a row of canes and tie a long lath from stake to stake horizontally; but this blows about, is very unsteady, and the whole thing soon rots. Very fair kinds of cure are these, like the doctor with his first two remedies.

Now for the infallible one. Choose a fairly good piece of ground; if under the shade of trees never mind, for our humble friend the Raspberry naturally takes shelter under some growth more imposing than itself. Clear the ground, manure it, and be sure no Raspberries have been ever planted there before, because they in time "grow sick of the same soil." Draw a straight line for a row. At the one end put a stout post (3 feet 3 inches above the ground), a similar one at the other end, and one or two, according to the length of the row, of slighter dimensions between. Run along a bit of galvanised wire, such as used for hanging clothes on, about 1 foot from the ground, and another about half a foot from the top of the posts; then plant single canes a foot apart all along one side of the wire, passing each cane in and out of the wires for support. You may have as many rows as you require by simply repeating this system. I don't think there should be less than 4 feet between the rows. This is the best plan for growing this fruit, and all others are very second-rate. Each bud has a fair chance; light, sun, and air are admitted. The birds have not so good a chance of hiding as if the canes were straggling about, and old birds have a habit of hiding instead of flying out when the boy or man shouts to clear the garden. Then perch on them they cannot as readily as when bent into arches. The whole, too, looks neat and tidy, and above all the fruit can be gathered readily and no canes trod upon.

I have seen an enlargement of this plan as follows:—A row of Raspberries planted as I recommend, then some rows of Currant bushes, also Strawberries, then another row of Raspberries. The posts, instead of 3 feet 3, being 6 feet high, and a light framework passed from post to post, the whole covered at the fruit season with fish netting. The owner of the garden told me he more than paid his expenses the first year, for he had a choice lot of Currants hanging very late, and all Raspberries, Strawberries, and Currants free from bird or boy depredations. The height of the whole enabled a grown person to go inside without stooping and gather the fruit comfortably.

I have spoken of the few varieties of the Raspberry; the question naturally may be asked, "Which are the best?" Of Reds, Carters' Prolific and Fastolf, also Northumberland Fillbasket and Red Antwerp, but my judgment inclines to the two first named. As to yellows, I know none so good as Sweet Yellow Antwerp.

The Raspberry delights in rich and damp soil, and no Raspberries I have ever seen equalled those grown in the fens; not, indeed, on peaty soil, but on those gardens in the fen towns and villages, which were naturally built on the islands in the fens to which the waters never or only partially extended, and where the subsoil is often, but not always, gravel; but whatever the subsoil, the soil above is deep, damp, and rich, partaking something of the fenny nature of the district around.

The autumn bearers I tried, but gave up some years ago. The Raspberry, next to the Apple, is especially a poor man's fruit. I know of cottagers who make from 30s. to £2 (a nice help towards the rent, by the way) each year by them, but then the children drive off the birds industriously, opening their mouths to shout and not to eat.

The uses of this fruit are various. Though not quite going so far as an old lady who used to declare "she always grew fatter during Raspberry time" (she was of the bag-of-bone style of beauty, always to my boyish idea), still I think the fruit is nutritious. Then no Currant tart is worth much for flavour unless it has a few Raspberries among the Currants. Each year I enjoy my tea the more when Raspberries crushed by a silver fork, and with milk (cream if you can get it), and sugar are added. They make, too, better jam than Strawberries, for Strawberry jam is sickly stuff. Then there is another use never to be forgotten—the sickroom use. Yes, never forget, my richer readers, to make every year plenty of Raspberry vinegar; put it in a number of small bottles, and when you hear of a case of sickness among your poor neighbours put a bottle in your pocket and send it up to the patient. Oh! the refreshment to the parched mouth and lips that a spoonful, often repeated, of Raspberry vinegar and water affords. What-

ever you forget of this paper of mine don't forget this part. I learnt this, as I have learnt almost all that is kind and good, of a woman. I looked out a lady's jam cupboard, saw rows of little bottles, and asked what they were. "Raspberry vinegar for the poor" was the reply. I made a note of that; you, good reader, make a note too.

In conclusion, I will add a little historic account of this fruit. Says old Gerard, who wrote A.D. 1633, "The Raspis (the Wiltshire peasant still calls them 'they Raspes') or Framboise bush, with leaves and branches not much unlike the common Bramble, but not so rough nor prickly, and sometimes without any prickles at all, having only a rough hairiness about the stalks. The fruit in shape and proportion is like those of the Bramble; red when they be ripe, and covered over with a little downiness; in taste not very pleasant." Old Gerard is speaking here surely only of the wild Raspberry. "The root creepeth far abroad, whereby it is greatly increased. This grows with prickles on the stalks or without them. The fruit is usually red, but sometimes white in colour. The Raspis is planted in gardens; it grows not wild except by a village near Blackburn in Lancashire. I found it also in a field two miles from Nantwich in Cheshire. The Raspis is called in Latin *Rubus idæus*, from the mountains of Ida, on which it groweth. In English Raspis, Framboise, and Hindleberry. The Raspis is thought to be like the Bramble in temperature and virtues. The fruit is good to be given to those that have weak and queasie stomachs." So much from old Gerard. In truth the Raspberry is a native of England, and may be found wild as near London as Weybridge, and grows wild most plentifully in Scotland.—WILTSHIRE RECTOR.

TRANSPLANTING AND RETARDING BROCCOLIS.

ALL varieties of Broccolis bear removal well during the autumn and after the plants have attained their full growth. I have removed thousands of plants about the end of October or early in November; in fact I adopted the plan for nine years as a part of the season's routine, and found the advantage of it in three ways—1, Securing an important crop from frost; 2, Retarding the plants and providing a longer supply of heads; 3, Turning ground to account that otherwise would have been occupied for six months longer by the Broccolis.

In the district where I was then engaged (Lincolnshire) the winters are occasionally very severe, and I have often known all the Broccolis in the neighbourhood killed unless some means had been adopted for protecting them. Indeed so uncertain is the crop, owing to the severity of the weather, that some of the best market gardeners of the district have ceased growing Broccolis, finding that it was not remunerative to have the ground occupied by an exhaustive crop that was so liable to be destroyed. By the system of transplanting similar to that alluded to on page 92 by Mr. Boyd I never failed in producing a full supply of this staple vegetable, and for three consecutive years I was never without Cauliflowers, including Broccoli, although I grew no Cauliflower plants under handlights.

As was mentioned on page 82 by "A KITCHEN GARDENER," Broccolis to insure a hardy growth must be grown thinly in a very exposed position. I do not quite agree that they require deeply dug and heavily manured ground, because, in the first place, such ground promotes succulent growth, and secondly, produces heads too large for a gentleman's family. The heads which I have always found to be the most highly appreciated were close, white, fresh, and moderately small.

In order to secure a hardy growth I planted the Broccolis in a field where the ground had been worked by the plough and had received no special manurial application. The plants were placed fully 3 feet apart. This distance permitted a free and full circulation of air amongst them throughout the growing season, which, with the moderately fertile and firm soil, produced dwarf woody stems very different from plants grown more closely together in the rich trenched ground of a sheltered garden. Broccolis thus grown in a field might safely have been left to pass the winter there, for they were so hardy in their nature as to resist even severe frost; but they were not safe from stock, rabbits, and even rats, which will travel a considerable distance to eat out the hearts of the plants during severe weather. The plants were therefore removed by cart-loads and laid closely in trenches in the garden on ground afterwards to be occupied by Celery or late Peas. Broccolis that had at 3 feet apart occupied half an acre of ground were thus accommodated in a very small quarter of the kitchen

garden, and the larger space of ground previously occupied was thus at liberty for being prepared for the succeeding crop of Carrots. A few days' work, therefore, effected a great saving of land. The economy of the practice of removing the plants in the autumn when they are grown in the garden is at the least equally great, for a considerable extent of ground is cleared in time to be prepared for Potatoes, Peas, and other crops that require planting or sowing earlier than the period at which late Broccoli is cut, while the plants removed can be accommodated in a much lesser extent of space than they previously occupied. This is a matter of great importance where garden ground, as is frequently the case, is limited while the demand for vegetables is great.

When the plants are grown in the firm soil of the field they remove with large balls and sustain only a slight check by removal, but when grown in the deeper, lighter, richer soil of the garden only a comparatively small quantity of roots and soil can be secured. In this case I have often covered the roots with a layer of decayed leaves or light vegetable soil before banking them up, which quickly induces fresh root-action, and the plants have always produced sufficiently large heads in the spring. The check caused by removal is beneficial rather than otherwise, by enabling the plants to resist extreme frost better than when it overtakes them suddenly when they are in a more active growing state.

A portion of the valuable early Broccoli (Snow's Winter White) was planted where it could remain to produce heads as early as possible, while another portion was removed, and the check given retarded the heading and afforded a succession. A portion of a second early variety was similarly treated, otherwise there would have been a failure in the supply towards the end of February; after that an abundance of heads were always certain until the supply ceased. By lifting in autumn plants of the latest varieties and layering them in the coldest situation at command—a shaded north border—I have cut heads until the 18th of June. That proves the advantage of autumn-lifting; the plants could not have been grown in the north border, for without that cool site an unbroken supply of Lettuces, Radishes, and Cauliflowers could not have been maintained during the summer.

I agree with "A KITCHEN GARDENER" that, as a rule, the period of Broccoli heading is not greatly influenced by the time of sowing the seed; yet to that rule I have found an exception and a valuable one. If ten different varieties are sown about the middle of March and another sowing is made of them a month afterwards there will be no appreciable difference in the time of heading; but if the second sowing of the latest varieties is deferred until the first day of June the plants head, if they head at all, decidedly later than those sown at the orthodox time. The plants from the late sowing are small and the heads are small; they may not exceed 3 inches in diameter—just the size that ladies, gentlemen, and cooks particularly appreciate for the dining-room; so indeed does the gardener when he has a plentiful supply of them in June. I have more than once cut Carter's Summer and Cattell's Eclipse Broccoli in the month named, but I could only do so by sowing the seed in the early days of the previous June; and after the plants had attained their season's growth by digging them up in the autumn and layering them in the north border. I ask "A KITCHEN GARDENER" to try the same plan with the excellent late varieties he has named.

So admirably did the firm soil and open field exposure answer for the cultivation of Broccoli and winter greens generally in promoting a woody and consequently hardy frost-resisting growth that eventually a portion of a field was fenced off for the purpose of growing those and other crops, where the Broccoli could remain to produce heads or be removed as was most convenient. By growing Broccoli both in the open field and sheltered garden I found what I did not expect to find—namely, that Snow's Winter White produces heads sooner when grown in the colder poorer field than in the warmer richer garden. The reason, I suspect, is that the plants in the former case with their hard stems and short leathery leaves were better matured than their longer-legged and more succulent congeners.

Owing to the prolonged mildness of the present winter Broccoli will probably be early, and the supply of them will be over much sooner than is convenient; it is therefore worth considering whether, even now, it is not desirable to dig up a portion of the plants and lay them in a north border or other cool place by way of retarding them. The heads would no doubt come smaller than if the plants were not disturbed; but

a supply of small heads is better than no large Broccoli. —J. WRIGHT.

MR. JAMES BOYD wishes to know whether the transplanting of Broccoli in autumn is general. I can recommend it as one of the best practices in the kitchen garden to have a good supply, for by doing so plenty come in a month later than if they were to remain where they were first planted. But I would advise one-half of each variety to be transplanted with plenty of manure in the trenches, which will require to be 2 feet apart each way. To insure them to come fine and white they ought to lean with their heads to the north, to keep the rays of the sun from the crowns, and if tied round with bast matting similar to Cos Lettuce, they will be as white as snow in the month of May.—WILLIAM GAIN, *Lymwood*.

NEW BOOK.

The Amateur's Kitchen Garden, Frame Ground, and Forcing Pit. By SHIRLEY HIBBERD. London: Groombridge and Sons.

This volume forms part of a series of gardening books for amateurs which the author has from time to time produced, and which have met with a considerable amount of public favour. This is certainly not the least useful of the series; it is also attractive, for it is well printed on toned paper and contains plans, diagrams, and illustrations elucidatory of the text, and also a few too highly coloured plates. These were, perhaps, included with the object of lightening the subject matter of the book, which the title might suggest as being somewhat heavy. Kitchen gardening is proverbially hard work. It consists largely of digging, trenching, and manuring; and while such branches of practice are thoroughly described, they are not treated in a manner so as to produce the backache in reading about them. The book is not by any means dull and dry, but is such that an amateur gardener might rest over—that is, read with pleasure even when fatigued after a hard day's labour. In this respect it differs advantageously from the usual style of kitchen-gardening books which are rather profusely issued from the press; yet while the style is free and pleasant the practice detailed is sound.

Besides treating briefly on the principles of kitchen-gardening, such as site, form, character of soil, &c., there are chapters on pits and frames, protecting, soils, manures, and the cultivation suited to crops of vegetables, herbs, and fruits usually found in moderate-sized gardens. These chapters are concise, and the instructions given are explicit. The selections of varieties are judicious and far superior to those given in a bulky volume recently issued, which was once a standard work. The author of the "Amateur's Kitchen Garden" has not fallen into the common error of recommending the Mazagan Bean as the best early variety, but correctly describes it as a "poor thing, but early." We agree that it is little better than a Horse Bean, but have never found it so early as the Early Longpod. The author's practice on Broccoli culture having been gained in the south he has not experienced the difficulty of preserving that important crop through the winter which is so hard to accomplish in northern districts. He has never found it necessary to lay the plants down, but he has found the value of sprinkling the ground between the plants with salt at the rate of ten or twelve bushels to the acre. Others who adopt this practice will find the value of it too, for, as the author observes, "it is certainly not a waste of labour or of salt, for the result is a wholesale destruction of vermin and a consequent protection of the plants from their ravages during those mild winter and early spring days, when slugs and other such come forth in troops and eat out the hearts of the best vegetables in the garden. It is worth remembering, too, that the salt is worth its cost as manure, and its presence in the soil will benefit the next crop." When the author found in his trials that Snow's Winter White Broccoli was in use from April 2nd to April 16th we think he had not the true variety, or the trials were conducted during an exceptional season. We usually cut heads of this variety in January.

The practical nature of the volume will be best exemplified by a few further extracts. Alluding to such necessities as walls and fences, low walls for fruit trees, which have recently been advocated in a sensational pamphlet, are rightly denounced—negatively, it is true, but none the less emphatically by the following sentence:—"The minimum height for a wall to be of any use in fruit-growing is 8 feet." Such a wall the author goes on to say "should be 9 inches thick, and have a coping

projecting forwards. If from 8 to 14 feet the thickness should be 13½ inches, and the coping 6 to 8 inches. If from 14 to 20 feet the thickness must be 18 inches, and the coping should project at least a foot. Hollow walls are formed by placing the bricks on edge alternately with their faces and ends outside, so that every second brick is a tie, and every course alternates in the order of facings, so that every end comes over and under a full face. By this means a 9-inch wall of great strength is obtained, and a considerable saving of bricks is effected.

"When a live fence is preferred to a wall the question will arise, What shall it be? Thorn is the quickest and cheapest, and if well arranged makes an effectual fence, but it is not well adapted for a garden. Common Privet soon makes a dense evergreen boundary, useful alike for shelter and to impose a check on thieves, especially when it obtains a height of 6 or 7 feet. The beautiful large-leaved Privet, *Ligustrum ovalifolium*, is as fast-growing and handsome a plant as can be used for a garden fence, and will cost but little more than the common Privet. Everybody knows that Holly is the finest of all boundary plants, but it should never be planted by a tenant at will unless the landlord is willing to pay for it, and in every case it will require the growth of years to thicken into a barrier and make a fair return for the money and labour invested in it. For general purposes common Privet is the very best of boundary plants for enclosing a garden, for it is not only evergreen and grows as close as a mat if planted thick enough, but it soon gets up to a useful height, so that no one can see through or over it."

The subject of edgings for walks and borders is admittedly a perplexing one to many amateurs, and, as the author sagely remarks, "one way out of the difficulty is to do without edgings;" but he does not leave the matter there. After a favourable word for the good and well-tried Box edging, and an unfavourable one for many edging tiles, which "split into fragments after hard frost," he says, "There cannot be a doubt that in a majority of cases a plank on edge fixed to posts driven down at distances of 8 feet or so, is the best possible edging for a kitchen garden. The paltry lath sort of stuff we sometimes see is not to be considered plank on edge. We want planks 1 inch thick and 4 to 9 inches broad, and they should not be sunk into the ground at all, but the border should be made up to them. The top edge may be rounded, and that is all the fine art possible, unless it is determined to pitch or paint them. Finally, a substantial stone moulding is the proper thing, and happy, in one sense at least, are those who can afford it."

The practice of growing fruit and vegetables on the same plot of ground is described as a mistake because it is unprofitable, and a variety of modes of associating these two branches of gardening are suggested; but fruit trees on lawns and in shrubberies are not considered incompatible. On this subject, which is now receiving the attention of our readers, we cite the following:—"It must be understood at starting, that while some kinds of fruit are decidedly ornamental, others are as decidedly not so. All the most valuable household fruits—Apples, Pears, Cherries, and Plums, are decidedly ornamental, and adapted to embellish the lawn and shrubbery, and give shade to the summer house and the croquet ground. There are several kinds not usually regarded as proper to the fruit garden that would be both useful and ornamental, as, for example, the *Siberian Crab*, which is one of the most beautiful of trees, and its pretty fruit makes a good preserve. All the varieties of Nuts are handsome, and make nice lovers' walks. For particular positions the Purple-leaved Filbert is well adapted, the leafage being of a rich bronzy-green colour and the nuts of excellent quality. Those who wish for ornamental trees that will contribute to the comfort of the household may easily find them, and we are quite sure no one will dispute the proposition that decorative horticulture might derive considerable aid from the trees and shrubs that belong technically to the fruit garden."

The closing chapter is headed "Reminders of Monthly Work." The twelve articles are, as they should be, short, and are interspersed with seasonable hints. We recommend the book as one from which amateurs and even professional gardeners may derive reliable information, which is the more acceptable as it is conveyed in an entertaining manner.

KEEPING GRAPES—DEW.

YOUR correspondent, "A NORTHERN GARDENER," in my opinion has made a very fair case in support of the above theory, but we want something more practical, for in my

opinion the dew theory will not serve any useful purpose if it is acted upon. Certainly I have observed a fine bunch of Muscats sooner blemished than otherwise would have been the case by artificial dew in the house in June for the want of air being given in time and sufficient. Through this, which everyone knows, and the berries of the bunch being too close, they damped a bit so as to disfigure the bunch. If air had been given and the house been dry this, I believe, would not have happened. After syringing Vines in the swelling state too, if the water hangs on too long on the bunches, it will cause the berries to damp in that early stage.

I believe it is from the soil that the difference is produced in the fruit of different places as regards the keeping qualities of the Grapes, and Muscats especially. I have kept Muscats into March at my present place with as much ease as I have had them in my last at Christmas, and I believe it is, as just said, from something in the soil that causes this difference. And the practical deduction I take out of such a case, which is not the first to my knowledge, is this—that in some places Muscats can be depended upon and can be recommended for good white late Grapes, and in other places they will not keep long enough, and the only safe way to prove the matter is by experiment.

My main reason for doubting "A NORTHERN GARDENER's" theory is the keeping qualities of Muscats, the products of different places, good keeping and otherwise when cut and under cover. The same character of fruit was the result when dew was not near them—in a room. If it was, then both samples were under the same influence. This being the case, one was much better keeping than the other, and the worst keeping was the best coloured. This shows that it is a condition of fruit that favours good keeping; but perhaps other correspondents may be able to throw a little more and better light upon this subject than I can.—R. M. R.

I WRITE to explain that this is the most constantly changeable climate I ever practised in. It is constantly oscillating between the very mild and very cold, and everyone who comes here from other districts remarks on this feature of the valley of Drumlanrig. It has excessively hot days followed by singularly cold nights; and if at any time the frequent variation of temperature is conspicuous it is in autumn—at the most critical stage for decay in Grapes. I never saw such heavy dews anywhere, nor so many hoar frosts. Your correspondent must not retain the impression that because we have so much cloud it is not frequently alternating between two extremes. The effects need not be described. Under glass and outdoors the condensation of moisture on every leaf, twig, and bud is most remarkable. I never was so lax and lenient in regard to temperatures in glass houses simply because the weather is so treacherous, hence the frequency with which dew or condensed moisture is noticed in all our houses, simply owing to the variation of temperature. It is a remarkable fact, however, that Grapes do keep better than I ever experienced or observed anywhere else. This may show "NORTHERN GARDENER" that I do not arrogate to myself credit for good management.—D. THOMSON, *Drumlanrig Gardens*.

NOTES AND GLEANINGS.

THE DUNDEE HORTICULTURAL SOCIETY offers upwards of £400 in prizes to be competed for on the 5th, 6th, and 7th of September. The chief prizes are for plants—£10, £6, and £4 being offered in the classes for twelve and for twenty stove and greenhouse plants. The principal prizes for fruit are £5, £3, and £2 for collections of eight varieties; and £4, £3, and £2 for four varieties of Grapes, single bunches. Numerous classes are also provided for cut flowers and vegetables.

—A HIGHLY successful gathering of Chrysanthemum growers and others interested in the movement was held at the Salutation Tavern, Newgate Street, London, on the evening of the 2nd inst. for the purpose of presenting a TESTIMONIAL TO MR. JOSEPH DALE, who has been for thirty-five years gardener to the Honourable Society of the Middle Temple, but who has now, owing to the encroachments of buildings, ceased providing a Chrysanthemum show in the gardens under his charge. Upwards of a hundred subscribers and friends partook of the excellent dinner which was provided. Mr. Shirley Hibberd occupied the chair with singular efficiency, and Mr. Potts the vice chair. After the loyal and patriotic toasts had been duly honoured, and after paying a graceful tribute to the memory of Mr. Samuel Broome, who was in-

tered eight years ago that day, the Chairman in an admirable speech, in which the history of the Chrysanthemum and the works and qualities of its patron were sketched, asked Mr. Dale's acceptance of a timepiece and a purse of fifty guineas. Mr. Dale acknowledged the gift in a modest and manly speech. He had, he remarked, simply endeavoured in the best manner in which he was capable to discharge his duties to his employers, and also had the pleasure of giving the best aid in his power both to societies and individuals in extending the culture of the Chrysanthemum as a city and suburban flower; he had been complimented by H.R.H. the Prince of Wales, but a greater honour even than that he esteemed the tribute paid to him by his friends and co-workers. The timepiece contained the following inscription:—"Presented to Joseph Dale, F.R.H.S., thirty-five years gardener to the Hon. Society of the Middle Temple, with a purse of fifty guineas, by friends who esteem his worth and appreciate his labours in the cultivation of the Chrysanthemum. January 31st, 1878." The toast "Gardeners and Gardening" was well responded to by Mr. Thomson of the Crystal Palace; Mr. Taylor, the winner of the first silver cup offered for twenty-four cut blooms of Chrysanthemums; and Mr. Oubridge, a celebrated cultivator of that flower. The evening was altogether a very enjoyable one.

— A CORRESPONDENT, "T. C.," writing to us from Sharpley, near Bolton, Lancashire, on the RAINFALL OF LAST YEAR, states that he is situated about a mile and a half from the Bolton Corporation reservoirs, and by the official gauge 81.12 inches were registered during 1877. At a gauge kept in the town, about the same distance south of Sharpley, 60.37 inches were indicated. So taking the mean they have 70.74 inches as the fall. And yet of the district writes "T. C.," "we were at times quite gay with flowers, whilst the Grapes were a more satisfactory crop than usual. A good deal may be done in a wet climate when you get used to it. The mean for thirty-five years is a little over 60 inches."

— IN Mr. E. A. Ormerod's "Notes of Observations of Injurious Insects" it is stated that Mr. W. D. Cansdale of Witham, Essex, mentions an application which he has found successful this year in freeing his Asparagus from a bad attack of the CRIOCERIS ASPARAGI (Asparagus Beetle). The mixture consists of half a pound of soft soap, quarter of a pound of flowers of sulphur, and about the same quantity of soot, well mixed together in a pail of warm water. In this the infested shoots were dipped, and on inspection the next day it was found to have cleared the larvæ. The plants were syringed afterwards with warm water (merely to clear off the dirt left by the dipping), and soon resumed a healthy appearance, and were thus saved from an unusually severe attack.

— WE have received the second number of the "MIDLAND NATURALIST," which contains amongst other subjects an interesting article on "The Distribution of the Genus *Rosa* in Warwickshire," by Mr. James E. Bagnell, who enumerates nearly fifty species and varieties of the wild Rose. Mr. Grove records the raising of a hybrid Fern. "His brother, Mr. T. B. Grove of Eastbourne, sowed a mixture of spores of *Blechnum corcovadense* and *Lomaria gibba*. Both of the plants from which the spores were taken were well grown, with stems about 3 feet high. Two fronds made their appearance from this sowing in advance of the rest, and were carefully transplanted. The other seedlings were normal, but these two, after throwing up at first fronds very similar to those of *L. gibba*, gradually changed their character. The pinnæ increased in breadth, the fronds became longer and more erect, and they have now produced fertile fronds intermediate between those of the two supposed parents. A well-known Fern-grower, who has seen the plants, said that he obtained a very similar hybrid about six years ago between *L. gibba* and *B. brasiliense* (a species allied to if not identical with *B. corcovadense*), which he exhibited at a meeting of the Royal Horticultural Society under the name of *L. hybrida*. He has since lost it. The correctness of his explanation was disputed at the time, but this independent production of what is nearly the same species seems to confirm it very strongly."

— "A. C. G." writes as follows in "The Journal of Forestry" on CORSICAN PINE AND GROUND GAME:—"I read that rabbits and hares would not touch the Corsican Pine (*Pinus laricio*), accordingly in 1874 I planted a few trees about 2 feet high in an open place in the centre of woods nearly 1000 acres in extent; this spot I selected as being in the heart of the chief game preserves. These trees are at this date growing well and

strongly, and have never from the time of planting till the present been touched by hare or rabbit. When they had so stood for a year I took courage, and in 1875 I planted about 1½ acre of open space (in the same woods, but about half a mile distant from the twelve planted) with the same Pine, purchased from the same nursery, of equal growth, and similar in every respect to the first. The rabbits and hares attacked them at once, and within a short time there was not an undamaged tree on the ground. Can any of your readers give a reason for the wholesale destruction of the second planting?"

— THE following dimensions of a handsome specimen of *CRYPTOMERIA JAPONICA* growing in the garden of A. Oakes, Esq., Downgate, Sandhurst, have been communicated by Mr. Hodgkin, the gardener:—"The specimen is 47½ feet high, 64 feet in circumference round the branches, 5 feet round the trunk of the tree 1 foot above ground, and 3 feet 8 inches 6 feet above ground. This tree was planted about twenty-three years ago—a small plant about 14 or 15 inches high."

— AS evidence that the culture of Roses is increasing a correspondent ("A. G. S.," *Inham*) informs us that he as an amateur is preparing about six thousand Rose trees. We hope in due time to have to record his success as an exhibitor, for such liberal preparations merit reward.

— MR. P. HENDERSON writes as follows in the American "Gardeners' Monthly" on *FUCHSIA RACEMOSA*.—"It is a most distinct species collected by Mr. Thomas Hogg in St. Domingo, 1872, but now for the first time offered for sale, we believe, either here or in Europe. It was exhibited in full bloom at New York Horticultural Society's show in June of 1876, and attracted general admiration. It grows not more than 18 inches high, forming a round bush, every shoot being terminated with a raceme of orange-scarlet wax-like flowers. It is of the easiest culture, and will undoubtedly become a standard plant both for the greenhouse in spring or for bedding out in partial shade in summer. As a market plant, from its distinct and beautiful appearance, it will have few equals."

— THE dwarf habit and free-flowering character possessed by the newer *ABUTILONS* render them very useful for various decorative purposes. One of the most attractive varieties, combining beauty of foliage with a profusion of flowers, is *A. tessellatum* Darwinii. The foliage is richly marked and is of itself highly ornamental, and flowers are freely produced when the plants are only a few inches high. This *Abutilon* will prove valuable for stove decoration during the winter, and for greenhouse, conservatory, and flower garden ornamentation during the summer. It strikes readily, grows freely, and flowers profusely at all periods of the year.

— IT will be remembered that a gold Banksian medal was last year awarded by the Council of the Royal Horticultural Society to Mr. Wills for his unique collection of seedling *Dracænas* raised by the manager of his Anerley nursery, Mr. Bause. This medal, in accordance with Mr. Wills's request, was handed to him without any inscription. Mr. Wills has since had the following inscription engraved on the medal:—"Presented by Mr. John Wills to Mr. F. Bause for valuable services rendered," and has handed it over to the skilled propagator and successful hybridist.

— PERHAPS some, says a correspondent in the American "Gardeners' Monthly" would like to know how to get two flowers instead of one from every flowering sheath of the *RICHARDIA ETHIOPICA*. As soon as the joint flower is cut or begins to wither, pull the stalk down through the open sheath clear to the bottom. At the bottom will be found standing close to the stalk another bud enclosed in a delicate covering. Cut the old stalk away as close as possible without injuring the bud, and if it has not been kept back too long it will grow up very quick. I have never failed to get both buds to flower. I never tie up the leaves close, but leave them free.

— RESPECTING MUSHROOM SPAWN "A KITCHEN GARDENER" writes:—"The most essential requirement to grow Mushrooms successfully is good spawn, and this I find most difficult to procure. Some time ago Messrs. James Dickson and Sons, Chester, sent me a few of their bricks to try, and I have done so with great satisfaction. The Mushrooms came up in close large clusters all over the beds from five to six weeks after inserting the spawn. Some of the largest which we gathered I had the curiosity to measure, and found them from 18 to 22 inches in circumference, and they were not black with old age, but showed that fine salmon colour underneath which indicated that they were not fully expanded."

— A GROWER of two hundred Vines writes to us that he thinks **INSIDE VINE BORDERS FOR LATE-KEEPING GRAPES** will very probably go out of favour. His Lady Downe's and Gros Colman with their roots outside are now splendid, whilst those planted in the centre of the inside with also their canes trained to the roof he was compelled to cut a month since.

OUR BORDER FLOWERS—FLAXWORTS.

THE Flaxworts are one of the most useful families of plants. We are indebted to our own as well as to other lands for these interesting occupants of our borders. Some of them are of slender habit and require support. I find with such plants as *Linum perenne*, *Lewisii*, *narbonense*, *monogynum*, *maritimum*, and others of their habit, it is good practice to place a few small branches round the plants tied round with a string and let the plants grow through them; they are unsightly when tied together in bundles. The flowers are but of short duration, but they yield a succession for a length of time. They delight in full sunshine and thrive in the ordinary border, but are the better for being supplied at times with fresh loam, leaf soil, or a little well-decomposed manure and coarse grit.

When established they last a long time, but are impatient of much moisture. They are increased by division in the spring. *Linum alpinum* and its white compeer are beautiful on the rockery. *Linum flavum* is one of the finest border flowers we possess in the early spring, and when well established the plants are like sheets of gold either on the rockery, border, or in a cold greenhouse. Grown in pots it is good for plunging in the spring garden. It strikes readily from cuttings in the spring or autumn; where it is pegged down the stem often strikes root and may be increased by division.—*VERITAS*.

THE ROOT-PRODUCING POWERS OF DIFFERENT COMPOSTS.

ON the 16th of October last I selected five young plants of *Iresine Herbstii* of nearly equal vigour (where they were not I picked off a few leaves of the strongest plants to make them equal), potted them, and half plunged them in a spare light in our Cucumberhouse. I also treated three plants of *Ageratum* in the same way, and I selected these two species because they are free rooters. The plants were potted in different descriptions of compost, as described in the following table, and were shaken out on November 21st, by which time all had made good growths and a considerable quantity of roots—in fact, the strongest plants were pot-bound. The experiment was conducted as fairly as possible, under the superintendence of myself, the foreman, and the young man in charge of the house, who had to water them when required with clean water out of the tank. In the table the proportion of roots in each case is indicated by the figures in the right-hand column—No. 1 indicating the fewest roots, No. 2 an increasing quantity, and so on.

IRESINE.		
No.	Description of compost used.	Proportion of Roots.*
1	Pure brown sand	1
2	Do. mixed with Standen's manure	3
3	Pure vegetable mould	4
4	Pure fibry loam	2
5	Loam, mould, and Standen's manure	3
AGERATUM.		
6	Pure silver sand	1
7	Pure fibry loam	2
8	Loam, mould, and Standen's manure	3

I may state that the different composts were put through a $\frac{1}{2}$ -inch sieve, except the silver sand and the loam; the latter being fibry was teased short by the hand—the object in both cases being to make a compost that would shake readily away from the roots when they came to be examined. The "pure vegetable mould" mentioned was taken from the heap that had covered the Vine border last winter, and consisted of nothing but thoroughly well-rotted leaves and stable litter in equal quantities. The roots in this mould were numerous, small, and fibry, and in quantity much exceeded the others. When the foreman and myself examined them we thought the proportion of roots in this case might be fairly represented by "5," but, to be within safe limits, I afterwards substituted a "4" for the "5"—and this, I am sure, understates the proportion if anything. The roots clung to the mould as if they had got hold of every particle of it. In the case of the

pure loam the roots, although not so numerous, were much the strongest, or rather thickest; this was very noticeable.

The results of the above experiment, though confirming my opinions on the subject on the whole, were different from what I anticipated. I confidently expected that the compost, consisting of loam and mould in equal quantities with a sprinkling of Standen's manure, would produce the most roots; but, as the table shows, it did not. Neither did I expect the sand and Standen's manure to produce more roots than the loam, though a good dose of the manure was given. I have, however, stated things as I found them, and your readers can form their own opinion on the subject. I am prepared to believe that other experiments with other plants might give different results, but cannot believe that in any case a poor soil fairly tested would ever exhibit the root-producing power attributed to it by some. As I said before, I recognise several factors in the production of roots than either rich or poor composts; but I am of opinion that rich soil and good growth will on the whole always be reckoned among the foremost agents in that respect.—J. S. W. (in *The Gardener*).

NOTES FROM CORNISH GARDENS.

TEHIDY PARK, THE SEAT OF G. L. BASSETT, ESQ.

TEHIDY PARK is one of the most extraordinary places that I visited on the north coast of Cornwall. Precipitous rocks full 300 feet high form its western boundary, against the foot of which the huge rollers of the Atlantic dash, often with terrific force, for there is nothing beyond but a wide waste of waters stretching right away to the shores of America. It is a wildly magnificent scene—a lonely coast not often visited by boats, so lonely that seals may occasionally be seen basking in the sun precisely like Scott's Phoca in the "Antiquary," which involuntarily comes to mind from the resemblance of the surrounding features to those portrayed by the great wizard of the north. From the edge of the precipice the park falls gently, rising again from a central valley to its inland boundary of mining lands, upon which I have no desire to dwell, for they are unsightly, and cannot possibly be regarded with pleasure except from a money-making point of view.

This contiguity of the sea on what may fairly be termed the windward side causes Tehidy to be swept very often by south-western gales, the scathing effects of which are visible in many places, especially along the margins of the more exposed belts and clumps of trees. Fine trees or shrubs might therefore not be expected to flourish here, and yet there are many such, forming an extraordinary sight, and affording lessons of exceeding value, not only as showing what to plant by the sea in southern counties, but also what will answer in exposed situations. Often have I told the merits of *Escallonia macrantha* as a climbing plant for clothing walls with perennial greenery and as a trailer for rockeries, but never have I seen except here such specimens of it standing out in the most exposed situations erect, compact, dense, with rich green glossy foliage, and regular models of symmetry, which even without a flower were exceedingly ornamental, but when covered with flowers must be strikingly beautiful. My readers will obtain a clearer idea of what degree of excellence these shrubs have been brought to when I tell them that one of them measured 51 feet in circumference close to the ground; and although the height of them was taken they were so well proportioned as to be all that one could wish, and infinitely superior to ordinary examples of this fine shrub. Mr. Davis, the forester at Tehidy, finds *Euonymus angustifolius* bears exposure to wind equally well, but it is much eaten by rabbits, which never attack the *Escallonia*; this is therefore the more useful as it is decidedly the more ornamental of the two.

The African *Laurustinus*, *Viburnum Tinus lucidum*, with large glossy foliage, is here in considerable numbers and in exuberant health and of extraordinary dimensions. One clump of it measured 14 feet high and was 42 yards in circumference, forming a regular mound of glossy foliage, and which I was told is at this season of the year literally covered with its white blossom. *Berberis Darwinii* with *B. stenophylla* and many others are all in a flourishing condition. But finest of all the shrubs is the wonderful specimen *Camellia* 17 feet high and 60 feet in circumference, having a dense clothing of deep green foliage from the ground upwards, and producing flowers freely. Although it was not my good fortune to see it in flower I was quite able to appreciate the remark that it was a striking object when in flower. Mr. Boscawen told me he has known it from twenty-five to thirty years and considers it the

* The tops also were generally in proportion to the roots.

finest example of its genus in Cornwall. Shelter is afforded it by common Holly mingled with *Ilex balearica*, both well qualified for such a purpose by their hardiness and sturdy growth.

Rhododendrons are extensively planted both as standards and bushes and are in excellent condition. Then there are Hydrangeas of large size and with blue flowers, which derive their colour from the ferruginous nature of the soil—an undoubted fact, which has led to the mixing of iron filings with soil by many who are desirous of obtaining a similar result by what they must suppose to be a similar agency. The failures which attend such experiments are no doubt an annoyance, and I would suggest saturating the soil with water containing a plentiful admixture of ochre, which is really the hydrated sesquioxide of iron, and which so applied is absorbed by the plants, inducing the flowers of the Hydrangea to come blue

instead of pink. *Arbutus Unedo* answers well, growing into large specimens, as do also *Phillyrea ilicifolia* and *P. buxifolia* and the Bay.

Of trees it will probably cause some surprise if I take first of all what is generally regarded as a tender shrub—*Benthamia fragifera*, but which here takes rank among trees, one specimen being 25 feet high. It is an evergreen, and is laden with scarlet fruit in winter, when it is really a magnificent sight. At Heligan, the seat of J. Tremayne, Esq., there are hundreds of them, and they are quite common in other Cornish gardens. It is a native of Nepal, and seed of it was sent to this country some fifty years ago by Sir Anthony Buller to Mr. Tremayne, who sent it to the Royal Horticultural Society when Mr. Benthall was Secretary, and by some means or other it came to be called after the latter gentleman. It should have a conspicuous position in every southern garden. *Ilex* flourish

Fig. 17.—TEHIDY.

here just as well as they do at Mount Edgcumbe. One which was measured is 70 feet high, with branches to the ground, where they measure 60 yards in circumference, and there are many more almost equally fine. It is much employed for the exposed sides of shrub belts, for which purpose it is admirably adapted, braving the high winds and growing in full vigour in situations where many so-called hardy trees would hardly exist. The Turkey Oak (*Quercus Cerris*) is also full of promise, but it has not had such a thorough trial as the *Ilex*. It is a tree that I much wish to see more frequently than I do, for it forms a handsome, symmetrical, spreading head, and its stem is quite as column-like as that of the Lucombe Oak. The Sycamore grows well, and so does the Beech. Of Conifers *Picea pectinata* is 100 feet high, and has a bole nearly a yard in diameter at 10 feet from the ground. It is really wonderful how well this lofty Fir answers in situations quite devoid of shelter. I have in Sussex watched specimens of it quite as large as that at Tehidy when swayed to and fro by a storm, to which their elastic stems yield like a piece of whalebone, springing back and retaining their erect posture as if high winds had never touched them. *Thuja Lobbian*, *Cupressus macrocarpa*, and *Abies Morinda* were all well represented, but *Wellingtonias* and *Deodars* do not thrive here.

I have thus dwelt upon certain trees and shrubs because I know the information so given will be turned to account in

many a wind-swept garden. Let me add a word of caution: Do not be tempted to plant large costly specimens; there is much risk of failure, and even if they do eventually answer four or five years are wasted before they are in full growth, and by that time small plants will have caught them and will soon rise above them. I have proved this repeatedly in my own practice, and have seen it still more often, especially in public gardens, where an immediate effect is often insisted upon. Plant small healthy plants, spend more money upon making good stations for them, and depend upon it you will have fewer failures.

The shrubberies at Tehidy are extensive and abound with fine shrubs, so fine as almost to induce forgetfulness of the fact that the stormy Atlantic is close by; but I do not forget it, and am going to indulge in a little faultfinding. One cannot but admire the fine specimens, and at the same time cannot help seeing that their development is being carried to an extreme. One would like to see more clumps, more grouping, more individuality in the features of the grounds themselves, and instead of a series of long interminable stretches of wide walks with parallel bands of turf on which are the specimens, an occasional cosy nook formed by a semicircular belt of trees and shrubs, with shrub clumps out on the turf; winding walks leading to circular enclosures formed in a similar way, but not having a heterogeneous collection of shrubs upon the lawn, but

with one or more specimens of a distinct species or several species of the same genus to impart a distinct character to that particular lawn. Thus for example there might be a *Benthamia* lawn, a *Magnolia* lawn, an *Embothrium* lawn, a *Cedar* lawn; not that either one of them should necessarily contain nothing but *Magnolias* or *Benthamias*, but that such should predominate sufficiently to impart distinction.

Another feature which might be introduced here with the happiest effect is an avenue. From the principal entrance a drive runs in a straight line through the park for a considerable distance without overlooking any agreeable prospect or feature of interest, and which moreover in stormy weather must be still more bleak and dreary here. An avenue further has a beauty of its own, for its features vary not only with the seasons but with every gleam of sunshine, every passing cloud, and instead of a tame monotonous drive there might be introduced here a feature that in course of time would become extremely beautiful. Hillard's observations on the avenue at the Poggio Imperiale at Florence will serve to enforce my meaning. He says, "The man is fortunate who can call such an avenue his own. It matters little what is at the end of it, whether a palace, a villa, or a cottage. It includes in itself all the elements of a landscape. The restless play of light and shade, the majestic canopy of foliage, the wind music that storms or whispers through it, the trunks regular but not monotonous, and ever revealing the fine accidents of perspective, are full of fresh suggestions and unworn exhilaration to a mind at all sensitive to natural beauty."

Here I must leave Tehidy, not that the subject is exhausted, for I have given no elaborate description of its gardens through which I made a hasty round, seeing as I went an excellent vegetable garden, fruit trees well managed and bearing abundant crops, *Roses* in a sheltered garden finer than any others I had seen in Cornwall, which cannot be termed a *Rose-growing* county; and shrubs and trees such as I have described them, affording useful lessons, which shall be turned to account in these pages as time and opportunity shall serve.—EDWARD LUCKHURST.

BROAD BEANS.

BROAD BEANS, although not generally considered so great a luxury as many other vegetables, are nevertheless much appreciated by many, and in all gardens of any extent a portion of the ground should be set apart for their cultivation. To grow *Broad Beans* well they must be planted in a strong rich soil. Ground which produces fine *Onions* will always grow good *Beans*. Ground intended for the first crop should be deeply dug or trenched about the end of January, and a liberal quantity of manure should be added when the soil is the least poor. The first spring sowing may be made about the first week in February. Drills about 3 inches deep and 2 feet apart should be drawn with a draw hoe. The seed should be rubbed in red lead and then placed in the drills singly from 1 inch to 2 inches apart. When ground is scarce two drills may be drawn quite close together, and both planted to form a double row. A small patch sown once a month until July will give a succession until the end of the season. When the plants are 6 or 8 inches high a good quantity of soil should be drawn to the stems, and as soon as they are 3 feet high the point should be taken out of every plant. This causes them to pod and fill-up quickly. Where very early *Beans* are required the seed is often sown the previous November. When this is done the soil may be a little lighter than for spring crops, and the position should also be drier. In unfavourable localities where success cannot always be depended on the autumn-sown crop, a few to supply an early dish or two may be sown and raised under glass in spring, and be planted out when they are about 6 inches high. The best varieties for all purposes are Johnson's Wonderful, Green Windsor, Monarch Longpod, and Beck's Green Gem, the last-named only growing about 1 foot high.—G. A. K.

PRUNING FRUIT TREES.

I WISH to say a word on the pruning of fruit trees. My experience suggests that young bush and pyramid trees are often cut too severely, which results in strong growth and few fruit spurs. I planted trees of Apples, Pears, Plums, and Cherries in moderately strong soil eight years ago. A portion of the trees were pruned in the orthodox manner annually, the other portion having received scarcely any "assistance"

from the knife, and pruning of them has been limited to thinning-out the branches. The slightly-pruned trees have yielded more than twice the quantity of fruit over those closely pruned, and the former are twice the size of the latter, and many of them have grown into natural pyramids and well-shaped bushes. In soil where the trees grow freely excessive pruning results in exuberant growth, unless root-action is also proportionally restricted.—A PLAIN GARDENER.

VRIESIA SPECIOSA.

AN old stove plant in my collection I observe always attracts the attention of visitors on account of the rich zebra-like marblings of its leaves, which show to great advantage when the plant is elevated. It is, indeed, one of the best shelf

Fig. 18.—*Vriesia speciosa*.

plants I possess. It is of easy cultivation, and is propagated from the suckers the same as the *Pine Apple*, and I have never any difficulty in disposing of the pretty young plants. The plant grows freely in a light open compost of fibrous peat, sphagnum, and charcoal. A gardener visiting me the other day told me the plant was a *Tillandsia*: he may be right, but I prefer adhering to the old name. I can recommend this as a shelf plant, for when well grown it is very beautiful.—M. D.

[We concur that *Vriesia speciosa*, syn. *Tillandsia splendens*, is an attractive "shelf plant," and still more beautiful and more valuable are *Tillandsias musaica* and *tesellata*.—EDS.]

SOW GOOD SEED, says the *Prairie Farmer*, for the following good reasons:—A seed in the process of germination under the action of moisture and heat, has its starch converted into a saccharine fluid, which with the gluten furnishes the first nutriment for the young plant. As the plant grows the roots begin to absorb nourishment from the earth, but while this is taking place absorption is also going on from the constituent parts of the grain until it entirely disappears, leaving only the hull or skin. From this we may see the importance of using only the best and heaviest seed, since during the first growth of the plant the seed is the life; and until a very

considerable growth is attained the plant still continues to draw nutriment from the seed : hence the better the seed the stronger the plant, and the weaker the seed the weaker the plant. If we want an even and vigorous growth we must sow none but the best and heaviest seed. It is true the effect is not seen in a single crop, except to the critical observer. Followed up it soon becomes apparent to the most careless observer. It is also true that degeneration proceeds much faster than regeneration : hence, again, the reason why careful cultivators are always enabled to realise the best prices for their products.

THE ECONOMIC USES OF FLOWERS.—No. 2.

INCIDENTAL mention may now be made of some of the other uses of flowers at home and abroad.

The medicinal substance called *semen-contra* is obtained from plants belonging to the family of Composites ; according to Batka it is yielded chiefly by *Artemisia Sieberi*, *Besser*. The flower-head is the part of the plant employed. Santonine, the active principle of the drug, is valued as a vermifuge.

In France the flowers of *Malva sylvestris* and *rotundifolia*, and of *Althæa officinalis*, *Nymphæa alba*, *Verbascum Thapsus*, *V. lanatum*, and *V. nigrum* are officinal, emollient, and demulcent, furnishing a pure mucilage.

The Marsh-Mallow is cultivated in certain districts of England and held in repute as a medicinal plant, being used chiefly in fomentations and gargles.

The flowers of the well-known Marigold (*Calendula officinalis*) were formerly used in soups and broth and as a carminative, but they are now chiefly employed to adulterate saffron.

The flowers of *Lyperia erocera*, of South Africa, resemble true saffron in smell and taste, and have similar properties ; yielding a fine orange colour, they have been imported into this country for dyeing purposes. The flowers are in daily request with the Mohammedans at the Cape, who use them for the purpose of dyeing their handkerchiefs. They possess similar properties to saffron, and as an antispasmodic, anodyne and stimulant, according to Dr. Pappe ("*Flora Capensis*") ought to rank with the *Crocus sativus*.

The flowers of the yellow Lady's Bedstraw (*Galium verum*) have been used in England in the place of rennet to coagulate milk.

Saffron flowers and those of the Embuch are employed for dyeing in Turkey. Those of *Althæa filicifolia*, *Cav.*, are used in Turkestan to form cataplasms for inflammatory swellings.

The extremely fragrant flower-heads of *Santolina fragrantissima*, *Brick.*, are sold in the shops of Cairo as a substitute for Camomile, under the name of Babouny or Zeysoum.

An infusion of the dried blossoms of the common Cowslip is drunk in some counties in England under the name of Cowslip tea. The blossoms communicate an aromatic fragrance to home-made wines, resembling that of the Muscatel wines of the south of France.

An infusion of the flowers of the Lime (*Tilia europæa*) separated from the bracts, is considered to be a sovereign remedy for headache in Switzerland and Germany. The flowers of the *T. argentea*, *Desf.*, have been met with in Europe as a substitute for the flowers of *T. parviflora* and *T. grandifolia*, *Brick.* The flowers of the former species have larger bracts, which are of a greener colour than the officinal, finely reticulated above, and underneath densely covered with stellate hairs, which readily separate when dry, forming a woolly irritating powder ; the flowers have, particularly in the fresh state, an odour reminding of Hyacinth and Lily of the Valley.

An infusion of the flowers of the Linden is much used on the Continent, being considered good in vertigo and spasms, and against coughs, for its expectorant properties.

In North America *Calycanthus lævigatus* and *C. floridus* are much prized for their highly-scented inconspicuous flowers, which are often gathered and put into clothes-drawers to impart their perfume.

Evodia hortensis is a favourite plant in the gardens of the natives of the Pacific Islands, being used for scenting Cocoa-nut oil.

The small flowers of *Pandanus odoratissimus* are very fragrant, and from them an oil, known as keora oil, is obtained. The perfume is extracted chiefly from the male flowers. The floral leaves themselves are eaten either raw or boiled.

The flowers of a Jasmine, the *Nycanthes arbor-tristis*, shed a delicious fragrance in gardens, where they bloom only during

the night. It is at sunset they open, and before the morning the ground is covered with the fallen corollas. The native women collect them in India, and stringing them on threads, wear them as necklaces, or twine them in their hair. The orange-coloured tubes dye a beautiful buff or orange colour, with the various shades between them, according to the proportion and mode of conducting the operation, but no way has yet been discovered of rendering the colour durable.

In the East the petals of the flowers of *Hibiscus rosa-sinensis* are used for blacking shoes, and the women employ them to colour their hair and eyebrows black. They are also eaten by the natives as pickles. The flowers are used to tinge spirituous liquors, and the petals when rubbed on paper communicate a bluish-purple tint, which forms an excellent substitute for litmus paper as a chemical test. In China they make these large handsome crimson, yellow, and white flowers into garlands and festoons on all occasions of festivity, and even for their sepulchral rites.

The flowers of *Acacia Farnesiana*, known as cassie, distilled yield a delicious perfume. In Borneo the fragrant flowers of *Areca Catechu* are mixed with medicine for the cure of many diseases.

In China many odoriferous flowers are much used in scenting teas. Ball, in his work on "Tea," p. 142-164, gives a description of some. Among these the following may be enumerated :—The best kinds of Caper or Sonchey teas are said to be scented more or less with the curious green flowers of the Chu-Lan (*Chloranthus inconspicuus*, *Swartz*), although Fortune states that those of the *Aglaia odorata*, *Lour.*, are used. These writers agree, however, in the following :—

Pac-shoen, the sweet-scented pale yellow flowers of *Gardenia florida*.

Quy-fa, or Kuey-Noa, the yellow flowers of *Olea fragrans*.

Moo-ly-Hoa, the white flowers of *Jasminum Sambac* and *J. paniculatum*.

The *Mesua ferrea* is much cultivated in Java and Malabar for the beauty and fragrance of its large white flowers. When dry they are mixed with other aromatics, such as Sandalwood, and used for perfuming pomades. The blossoms are found in a dried state in the Indian bazaars, and are called Nagkushur ; they are used medicinally, and much esteemed for their fragrance, on which latter account the Burmese grandees stuff their pillows with the dried anthers.

The large flowers of *Michelia Champaca* are celebrated for their exquisite perfume, and the tree is highly venerated by the Hindoos. The natives adorn their heads with them, the rich orange colour of the flowers contrasting with their dark black hair. Sir W. Jones states that their fragrance is so strong that bees will seldom, if ever, alight upon them.

Large numbers of the fleshy variegated calyces of the *Hibiscus Sabdariffa* are dried and stored in parts of Africa ; in this condition they retain their fragrance, and serve for the purpose of giving the soups of the natives an acid flavour almost as sharp as vinegar. The calyx and capsule freed from the seeds make excellent tarts and jellies ; a decoction of these sweetened and fermented is commonly called in the West Indies sorrel drink.

The natives of India are very fond of the flowers and leaves of *Clerodendron serratum*, which they eat as vegetables.

From the flowers or blossoms of the Red Gum Tree (*Eucalyptus rostrata*), the natives of West Australia make a favourite beverage by soaking the flowers in water. The *Banksia* flowers are also so steeped to extract the honey. The natives are extremely fond of the infusion, and in the season their places of resort may be recognised by the small holes dug in the ground, lined with the bark of the Tea tree, and surrounded with the drenched remains of the flowers, called by them man-ryt. They sit round this hole, each furnished with a small bunch of Pine shavings, which they dip and suck until the beverage is finished.

From the flower of the Budjan shrub (*Dryandria Fraseri*) a nectar or honey is also obtained, much sought after by the natives.—P. L. SIMMONDS (in the *Chemist and Druggist*).

RAINFALL IN 1877.

I HAVE now the pleasure of sending tables of the fall of rain at some of the principal country seats in Scotland and Ireland, and also a little list which shows that the fall last year was in excess of the average in all parts of the country. The table on page 92 in your last issue gave for England and Wales the following extremes :—

<i>Driest</i> —Dalby Hall, Melton Mowbray	25.58 inches
<i>Wettest</i> —Brathay Hall, Ambleside	96.56 "
The Scotch List gives— <i>Driest</i> —Springwood Park, Kelso	34.01 "
<i>Wettest</i> —Inverinate, Loch Alish	92.60 "
And the Irish— <i>Driest</i> —Belle Vue Park, Dublin	33.49 "
<i>Wettest</i> —Florence Court, Enniskillen	68.56 "

It must, however, be remembered that it is usual for wet localities to be avoided in selecting sites for important residences, and therefore the extremes above given are far within the true extremes. Upwards of 100 inches fell at many stations both in England and Scotland.

I now come to the question of the relation of the fall in 1877 to the average, but here I should like to be discursive. In the first place I wish to ask gardeners when they change from one service to another always to be careful to leave their rain accounts in good order, and to call their successor's attention to the gauge. I think that I am within the mark in saying that dozens of otherwise good registers have been spoiled by a break in the register during a "change of gardeners." Secondly, I wish that people would never do as I have done at the beginning of this paragraph—viz., write of "the average" without completing the phrase by saying "the average of the last—years:" this is essential, because unless comparisons are made with the same group of years, or with very long periods, they are apt to be misleading. In the following table the 1877 records are shown to be generally and greatly above the average 1860–69, which average I have elsewhere shown ("British Rainfall," 1871, p. 65) to be nearly identical with that of the previous half century. The stations in this table are arranged from south to north, and the western stations are printed in italics. I regret the paucity of the Irish records, but until lately the rainfall was rarely observed in Ireland, and an Irish engineer told me that they did not require to know the rainfall for drainage purposes. Whether they were as successful without the information as they would have been with I did not think it necessary to inquire.—G. J. SYMONS, 62, Camden Square, N.W.

NOTES ON VILLA AND SUBURBAN GARDENING.

ROSES FOR COVERING WALLS, &c.—Many of the Hybrid Perpetuals, Hybrid Chinas, Bourbons, Tea-scented, Noisettes, Ayrshires, Banksians, and Sempervirens or Evergreen Roses are suitable for training against walls or for covering trellises or arbours, and few plants look more beautiful when the objects to which they are trained are well covered. The Hybrid Perpetuals do not make such strong and rapid growth as the Hybrid Chinas, Teas, Noisettes, Sempervirens, and other rampant growers; nevertheless, the following varieties are robust and possess brilliant and striking colours, and will grow under good treatment from 10 to 10 feet high. They therefore have much to commend them for low walls or for covering the lower parts of high walls by planting them alternately with the more luxuriant growers—Anna Alexieff, Camille Bernardin, Charles Lefebvre, Duke of Edinburgh, Edouard Morren, Général Jacqueminot, John Hopper, Jules Margottin, Madame Clemence Joigneaux, Maréchal Vaillant, Paul Neyron, and Sir Garnet Wolseley. If the above selection were planted alternately with summer-blooming Clematises, such as Miss Bateman, lanuginosa, Jackmanii, Rubella, and Rubro-violacea, a grand display of bloom would be produced throughout the summer. Sir Joseph Paxton and Souvenir de la Malmaison are two very free-blooming Bourbon Roses suitable for low walls. The last named is one of the best autumnal-blooming Roses our gardens possess, and its foliage is always clean and good.

Of Noisettes, Aimée Vibert, Bouquet d'Or, Céline Forestier, Cloth of Gold, Lamarque, and Réve d'Or are sorts worth adding to every collection, but in most districts they require a south or west wall. Aimée Vibert and Céline Forestier are undoubtedly the hardiest and are profuse bloomers, while Cloth of Gold is usually very shy in blooming, but where it does succeed its blooms are very beautiful.

The never-failing Gloire de Dijon of the Tea-scented Roses stands pre-eminent, and should be planted wherever there is room if only for one plant. If its blooms are not always up to the orthodox exhibition standard it supplies us with both the first and last Rose of summer, blooming not by mere "dribbles," but in great quantities. Our gardens are now enriched by several seedlings of this good old Rose, and amongst them are Belle Lyonnaise and Madame Trife, which possess the same habit and hardness of their parent, but not such constant-blooming properties; they are, nevertheless, valuable additions to the autumnal-blooming Roses. Other good climbing Roses among the Tea-scented are Cheshunt Hybrid, Madame Maurin, and Maréchal Neil. The last named is undoubtedly the finest yellow Rose in cultivation, and will succeed in almost any aspect in the south of England. We prefer this Rose worked on the Briar, which stock also suits Gloire de Dijon and nearly all other Teas.

Blairii No. 2, Charles Lawson, Paul Verdier, and Vivid of the Hybrid Chinas, make grand pillar Roses and for covering high walls; they require but little pruning—merely the old and weak wood being taken out, and the extreme points of the shoots removed.

Félicité Perpetuelle is of a quick rampant growth and admirably suited for covering arbours or arches. Its clusters of creamy white flowers are in summer very attractive, and its dark green leaves continue fresh throughout the winter.

Banksian Roses are not met with so frequently as they merit, perhaps from the fact that they require sheltered situations: and are neither suited for pillars nor standards; but both the white and yellow Banksian grow luxuriantly on a south wall, rapidly covering a large area. The flowers of these elegant Roses are small, and are produced in clusters on the previous year's wood, and the system of training and pruning required differs materially from that laid down for all other Roses; merely nailing-in the strong branches to the wall at their full length, and thinning-out any crowded shoots or weakly growths, is all that is required.

Banksian Roses also bloom earlier than the other sections, and flowers are generally to be had from April until June.

The process of planting all Roses against buildings requires both care and forethought, for in the preparation of the soil success in a great measure depends. After the completion of buildings the ground which surrounds the walls is almost invariably of the poorest, in which case it ought to be entirely removed and replaced with a richer compost. A good, substantial, and lasting soil to plant in is absolutely necessary, or else the growths will be scanty and fall a prey to both green fly and red spider. Among the other causes of failure is the want of sufficient moisture at the roots throughout the summer months, for when Roses are planted against high walls they do not receive an equal share of the rains as do plants that are placed in more exposed situations, therefore the frequent use of a garden engine is necessary for insuring clean and luxuriant foliage.

Any young shoots springing from the base of all climbers must be encouraged, and the older shoots should be cut away to make room for them. By adopting this system the base of the wall is prevented from becoming bare, which is too frequently the case. Encourage the strong shoots of Hybrid Perpetuals, and nail them in their full length. This practice and keeping the growths clean will aid in the production of fine blooms throughout the season.

We omitted mention last week of that fine climber *Wistaria sinensis*, which although deciduous is very valuable for covering large walls, and its long racemes of lilac Pea-shaped blooms are always welcomed. The plant is of such a rambling habit that we have known it cover the south side of several houses. It is also a very profuse bloomer, bearing on the short spurs of the long shoots. We have known *Wistarias* make no progress in growth after being planted for a season or two, and all at once they have made a start, growing away most extraordinarily.

WORK FOR THE WEEK.

KITCHEN GARDEN.

SHOULD mild weather prevail a sowing of early and second early Peas may be made in the open ground, also Broad Beans, sowing between the rows of Peas a single row of Round Spinach, which will not in any way interfere with the growth of the Peas, and coming in soon will render available for other purposes the ground occupied by the winter crop. Early crops of Peas when appearing above ground are often attacked by birds, particularly sparrows. We find nothing so effectual in preventing their attacks as occasionally dusting the Peas whilst damp with soot or dry wood ashes; these dustings we also find equally effective against slugs. Winter Spinach should only have the large outer green leaves picked off for use; but the plants should be gone over frequently, removing any decayed leaves and stirring the soil between the rows frequently, removing all weeds. Late plantings of Celery may now be taken up with a ball of soil to each plant, laying them in at the back of a north wall, covering the blanched part with cocoa refuse or spent tan, and protecting with mats in severe weather. The Celery will thus be prevented running for some time longer, and the ground it occupied will be set at liberty for trenching preparatory for other crops.

Forcing Department.—Admit air freely to Carrots and Radishes in frames, applying water if it is necessary at a temperature of 65°, and thinning out the early-sown crops to 2 inches apart if in rows, allowing an inch more if broadcast. Another sowing of those crops should be made now. The bed of hot dung and leaves for this sowing need not exceed about 18 inches high, provided the frame is filled with the same material to within a foot of the glass; a depth of 4 inches of rich light soil brings the plants still closer to the glass, yet allows ample space for growth. If sown in alternate rows 8 inches apart the Radishes will be off before the Carrots require the whole of the space. Early Nantes Carrot is good for this sowing. Plant more Potatoes in pits or frames; these usually give better results than those planted earlier. Attend to those growing vigorously, earthing-up such that require it, and see they are not drawn by lack of air; when the sun is very powerful the lights may be removed. Introduce fresh roots of Asparagus, Sea-kale, and Rhubarb, also Mint and Tarragon, keeping up the supply of small saladings by frequent sowings. Celery may now be sown for an early crop. Incomparable Dwarf White and Leicester Red are the best for this sowing. Admit air freely to Lettuces in frames, stirring the soil about the plants; similar remarks apply to Cauliflowers. Those not having hot dung at command may sow Celery seed in cold frames or ground vineries, placing in about 6 inches thickness of light rich soil, and if the glass be not more distant from the soil than a foot all the better. Seed of Early Paris Market Lettuce may be sown in rows 6 inches apart, with a row of French Breakfast, Wood's Frame, or Sutton's White Forcing Turnip Radish between, and French Forcing or Early Nantes Carrot in rows 6 inches apart with Radishes between the rows; Early London, Walcheren, and Veitch's Autumn Giant Cauliflower, if sown now and the plants pricked out on a warm border when the second rough leaf appears, and afforded protection for a time, will afford a succession to those wintered under handglasses or in frames.

HARDY FRUIT GARDEN.

The recent frost, with snow in some districts, has been very acceptable. The buds of fruit trees are in a forward state, but not so advanced as to create alarm yet. Timely attention should be given to providing the requisite protecting material. Apricots are swelling the buds rapidly, but where there are wide coping-boards or glass copings they will afford ample protection until the blossom shows colour, when the protective material must be applied. Experience has taught us that stout canvas or frigidomo are the best materials, but their cost has induced the adoption of scrim canvas, which can be had in widths of 8 or 4 yards, and of any required length. We secure the canvas to the coping, and place battens 2 inches square at 8 to 4 feet apart, one end being fixed in the ground, the foot about 2 feet from the wall, the top to the coping flush with its outer edge. We have a loop formed of twine fastened to the canvas, and a nail in each batten or pole at 18 inches to 2 feet from the ground, so that the loops being secured to them the canvas cannot be displaced by winds nor beat against the blossoms. The material is used only in case of frost, being removed whenever the weather is mild. This mode of protection is much superior to that of herring nets, which, however, are useful, and in a double fold are often sufficient to prevent injury from frost until sufficient foliage is produced to afford natural shelter. Spruce branches are also useful when more efficient protection cannot be obtained. A crop so important as wall fruit should, however, not be trusted to makeshift appliances.

FRUIT HOUSES.

Vines.—Those in flower, which will be the case when fire heat was applied early in December, should have a temperature of 65° to 60° at night, and 70° to 75° by day. We now keep the atmosphere somewhat drier by freer ventilation, leaving a little air on at night, yet keeping the floors sprinkled three times a-day during bright weather. Any shy-setting Grapes may have the pollen distributed by rubbing the bunches gently with the hand; stop the laterals at the first leaf, keeping those stopped at one joint throughout the season, but those beyond the bunch may be allowed to make two or more leaves before stopping them, provided there is space for the exposure of the foliage to the light. Avoid overcrowding the foliage, it being better to reduce the laterals than do that. The Vines in the house started early in January will now be in leaf and showing fruit. Disbud when it is seen which shoots are likely to afford the best bunches. One bunch on a spur is as much as is calculated to finish satisfactorily; but if there be space, the spurs being widely distant along the rod, two shoots may be left, it being clearly understood that only one is to be allowed to carry fruit, the duplicate only remaining until choice can be made of the best, and in case of two shoots being retained one of them ought to be near the main rod, so as to keep the spurs as short as possible. See to the fermenting material on outside borders. Where the heat is declining renew with fresh litter; that in the house, if any, being turned frequently will give off ammonia, which we find conducive to the size, colour, and substance of the foliage and the immunity from insects, particularly red spider. All inside borders should be frequently examined, and when water is requisite it should be applied at not less than the mean temperature of the house, or 5° to 10° higher than that of the border at a foot depth. The house for affording fruit in July and August may now be started. Damp the rods three times a-day and every available surface. 50° being a sufficiently high night temperature to commence with, and 65° by day with sun.

Peaches and Nectarines.—Proceed with disbudding in the earliest house—that to which fire heat was applied early in December, removing all shoots not having fruit at their base and not required for extension. The extensions should be laid in at 1 foot apart, and growths emanating from those of last year may be retained at 12 to 15 inches asunder. Branchlets having fruit should have a shoot preserved at their base to take the place of the one now carrying the fruit, and those above it having fruit at their base to be stopped to two leaves, or if the fruit have no shoot at its side a shoot above it must be retained, pinching out its point at the second or third leaf. Reduce the number of the fruit, leaving one, or at most two, to a vigorous shoot. In watering the inside border, weak liquid manure slightly higher in temperature than that of the border will be advantageous to the swelling of the fruit. Admit air freely in order to have the growth for next year's fruiting short-jointed and the foliage thick and leathery, avoiding cold draughts, which chill the foliage and check the growth of the young fruit. In frosty weather it is safer to allow the temperature to rise somewhat higher from sun heat than to open the ventilators too much to reduce it. To afford fruit in July and early August another house may now be started, if it can be called starting, as we simply close the house, damp the trees twice a-day until the blossom is on the point of expansion, maintain a temperature of 50° by day, and increase it to 65° from sun heat. Make sure that the borders are in a thoroughly moist condition, not forgetting those in the latest houses, which are not infrequently neglected; ventilate the latest house very freely.

Melons.—Those sown as advised will now be in rough leaf. Pot the plants singly into 8-inch pots; or if sown singly, as is advisable, shift into pots a size or two larger, and again plunge them in the

bed near the glass. A stick should be placed to those intended for trellises, and the shoot be secured to it as it advances; but if intended to run over the surface of the bed stop the leading shoot at the second rough leaf. Sow for succession and for planting in frames.

Cucumbers.—As the days lengthen more moisture will be required, but the syringing must not be brought to act upon the foliage, it being sufficient if the walls, paths, &c., are damped during bright afternoons. Avoid sudden fluctuations of temperature; 70° to 65° at night, advancing with sun to 85° or 90° by day is suitable, giving a little air on all favourable occasions, closing early in the afternoon, when the house should be syringed. Look over the plants at least once, better twice a-week, removing superfluous fruit, thinning-out the foliage also to prevent it being too crowded, stopping at one or two joints beyond the fruit, and removing any decayed wood or leaves. The bottom heat must not be allowed to decline below 75°, but must be kept steady between that and 80°. Shift young plants into larger pots, placing a stick to those required for trellis-training, those for planting in pots or frames to run on the soil to be stopped at the second or third leaf, keeping the plants near the glass. Prepare fermenting materials and soil, which should be got in to dry, so as to be in readiness for pit and frame work when required.

ORCHARD HOUSE.

The trees, whether in pots or planted out, should all have been pruned and surface-dressed before this time. If not, see to it at once. In surface-dressing remove as the season is so far advanced about an inch of soil only near the stems, taking care of the large roots, removing 2 inches at the sides of the pot, replacing with rather strong turfy loam and well-decayed hotbed manure in equal parts, with a sprinkling of half-inch bones, ramming the compost well down, finishing within an inch of the rim of the pots. The buds are, however, swelling fast, and the roots will be active; when they are in that state disturbing the roots often results in the fruit setting badly. Pruning should be confined to the thinning-out of superfluous wood. The soil must be kept moist, especially in the case of trees surface-dressed in autumn, giving sufficient water to reach the lowest roots. Fumigate with tobacco if there are any aphids, and again just before the blossom expands. Ventilate freely, keeping the house as cool as possible without allowing frost to injure the trees. The heating apparatus, if any, should only be employed to exclude frost after the blossom show colour.

PLANT HOUSES.

Stove.—Cut down *Dracaenas* which have become leggy, potting the tops singly in small pots; if these are plunged in bottom heat and brisk moist top heat is maintained they will soon root. The stems may be laid horizontally and covered about an inch deep with spent tan or cocoa refuse. The young plants proceeding from them should be potted singly in small pots and be plunged in bottom heat until roots are formed, when they should be placed near the glass to induce a sturdy growth and good colour. *Allamandas* that have been kept dry should now be soaked, the ball afterwards being reduced half, repotting the plants in turfy loam light rather than heavy, with a fourth of old cow dung or leaf soil, and a sprinkling of sand, potting very firmly; cut the shoots back and arrange them on the trellis. *Bougainvillea glabra* should have the ball reduced about a third and be potted in turfy loam with a third of well-decayed manure, pruning close, as it is only the strong growths that afford good bracts. *Glerodendron Balfourianum* that has been kept dry for some time should have a little of the surface soil removed, but not injuring the roots at all, adding a little fresh loam. No pruning is necessary; the shoots should be merely trained to the trellises. Young plants required to be grown-on should be shifted with the ball entire, merely loosening the sides and removing the old drainage, affording the plants a good shift. *Scutellaria Mocciniana* cut back to two joints, keeping rather dry, and when the young shoots are grown an inch or two repot, removing the greater portion of the old soil, employing turfy loam with a fourth of old manure. It is a fine plant for late summer flowering. The points of the shoots strike freely in brisk moist heat. Do not stop the shoots, but keep established plants near the glass, so as to induce sturdy growth and large heads of bloom. It succeeds well in small pots, or several plants may be grown in a large pot. *Crotons* which have become too large may be cut back and kept rather dry; they break freely from the old wood. Any good long shoots may be potted and placed in brisk heat bottom and top, tying up the leaves loosely to enable them being placed closer. Wage incessant war against insects, especially mealy bug, which will now be active, and scale, than which there is no more certain mode of riddance than removal with brush and sponge, and fumigate frequently to prevent rather than destroy thrips and aphids. Get the soil for potting, which will now soon be required, prepared and under cover, where it will become sufficiently dry for use. On no account must it be used too wet, as the roots will not take to it freely. Turfy loam, peat, well-decayed manure, and leaf soil should be provided, also clean pots and crocks.

TRADE CATALOGUES RECEIVED.

E. G. Henderson & Sons, Pine Apple Nursery, Maida Vale, London.—*Illustrated Catalogue of Flower, Vegetable, and Agricultural Seeds.*

R. B. Matthews, 65 and 67, Victoria Street, and Richmond Nurseries, Belfast.—*Cultural Guide and Catalogue of Flower, Vegetable, and Farm Seeds.*

L. B. Case, Richmond, Ind.—*Botanical Index and List of New Plants.*

Walter Ford, Pamber, Basingstoke.—*Catalogue of English and American Potatoes, and Select List of Seeds.*

H. Elliott, Braywick, Maidenhead.—*Amateur's Garden Guide and List of Seeds.*

Louis Lhérait, 29, Rue des Ouches, Argenteuil, France.—*Catalogue of Asparagus, Strawberries, Vines, &c.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (Frenchay).—The "Vine Manual." Free by post if thirty-two postage stamps are enclosed with full address.

CHEMISTRY PLANTING (An Old Subscriber).—If you refer to No. 681 of this Journal you will there find a view and full directions for planting a cemetery.

LOMARIA GIBBA (Crawfordian).—Too much water applied to the roots, and the air of the house being too dry, cause the points of the fronds to die.

CYCLAMENS UNHEALTHY (H. T.).—The compost is right. Is the drainage efficient? and are the roots active and healthy? If this is the case and the plants do not improve as the season advances you will have sufficient evidence that the disease is chronic. Under any circumstances we should advise you to raise a fresh stock of plants from seed, as old plants often become stunted and diseased.

GUANO WATER FOR VINEYRIES (W. Sheldon).—A handful of genuine guano is sufficient for four gallons of water for placing in the evaporating troughs. Proceed with caution, using first a small handful and watch its effects, which if not satisfactory will indicate the necessity for more. Guano vapour keeps down insects and promotes the health and vigour of the Vines.

GROWING CUCUMBERS IN GREENHOUSE (Albert).—Fuchsias and Geraniums may be grown with Cucumbers in summer and early autumn, but not in winter, when the temperature necessary for Cucumbers would be too high for the flowers. You do not require a pitful of manure in summer, and will succeed best by throwing up a heap of rich rough soil on the floor, planting strong plants therein early in June, and watering with tepid water freely. Twelve good Fuchsias are Mrs. H. Connell, Lord Palmouth, Model Hercules, Rev. T. Whitshire, Wave of Life, Annie, Lucy Mills, Daisy Queen, Minnie Banks, Little Henry, and Miss Marshall. Geraniums—Jealousy, Kleon Riant, Imogen, Hetty, Mr. Chandler, Rev. M. A. Edgell, President Thiers, Acme, Ellen, Bibal, Annie Orton, and Mrs. Turner. These all belong to the same section, which we presume you want.

DAFFODIL UNHEALTHY (Mrs. J. H. M.).—Make a bed of pure peat in the open garden, turn your sickly Daffodil out of the pot, plant it in the peat, fasten the branches to the soil with pegs, and cover portions of them with peat midway between the tips and the main stem, and in due time your old plant will be restored to health and vigour, and many of the branches will have put forth roots. Sever them then from the parent plant and pot or transplant them to other beds. It is quite hardy, and we should cherish the old plant as a valuable addition to the flower border, giving preference to young plants for pot culture. It thrives well in peat, but only exists in loam.

RAISING EUCREMOCARPUS SCABER FROM SEED (Fiddle).—Sow the seed in March in pots just as you would any ordinary flower seed—that is to say, drain the pot well with broken crocks, fill it to within an inch of the rim with fine rich soil, which make smooth and even, water it, and then sow the seed, covering it with fine soil, which press down gently; place the pot in a warm structure, taking a hotbed for choice, and the young plants will soon appear and should be pricked singly into small pots, grown on quickly in heat, gradually hardened, and then planted out. Take especial care not to bury the seed too deeply under the soil; much seed is so spilt.

ORANGE TREE UNHEALTHY (Adam).—Your Orange tree is probably infested with mealy bug. Wash every part of it, leaf and branch, and repeat the washing without loss of time upon the slightest sign of filth or insects upon it. Repot now if it is much pot-bound, or apply a top-dressing of rich loam, and water occasionally with guano water or other liquid manure. Any of the nurserymen advertising hardy plants in our columns can supply double blue *Hepaticas*. Your so-called Leek is the Tree Onion.

PLANTS FOR CARPET BEDDING (T. T.).—*Grasses* of various shades—*Mantha Pulegium gibraltarium*, *Cerastium arvense*, *Tagetes signata* pumila, *Sempervivum montanum*, *S. calcareum*, *S. tabuleforme*, *S. hirtum*, *Sedum glaucum*, *S. lydium*, *S. anglicum*, *S. pulchellum*, *Echeveria secunda* glaucum, *E. metallica*, *E. pumila*, *E. roosa*, *E. atro-purpurea*, and *Kleinia repens*, most useful for the greyish blue hue of its thick pointed leaves. *Yellow*.—*Festuca Golden Feather*, *Mesembryanthemum cordifolium variegatum*, *Arabis lucida* variegata, *Coprosma Baueriana* variegata, *Vinca major* elegantissima, *Lonicera aureo-reticulata*, *Sedum acre* variegatum, *S. Fabaria* variegatum, *Stellaria graminea* aurea, *Knapweed flavescens*, *Golden Balm*. *White and Grey*.—*Leucophyton Browni*, *Santolina incana*, *Cerastium tomentosum*,

C. Biebersteini, Antennaria tomentosa, Veronica incana, Cineraria ceratophylla, Cotyledon pulverulenta, Gnaphalium lanatum, Salvia argentea, Lobelia Duchesne of Edinburgh. *Crimson and Carmine*.—Iresine Lindeni, Coleus Verschaffelti, C. Verschaffelti splendens, Amaranthus melancholicus ruber, Alternanthera amena, A. magnifica, A. paronychioides major, and A. spectabilis. *Blue*.—Lobelia pumila grandiflora, L. speciosa.

SEEDLING ECHEVERIAS (*Idem*).—Echeverias raised from seed this spring can hardly be turned to account this season, but a fine stock may be so raised now for next year.

ALTERNANTHERAS GREEN (*A New Reader*).—You need have no misgivings as to the foliage losing colour, as cuttings in that state invariably make the most healthy plants, and assume their rich hues as they advance in growth.

SOWING NEMOPHILAS (*Amateur*).—If seed of the charming blue Nemophila insignis is sown now in shallow drills in the open air, the seed being covered half an inch deep with light soil, you will have a fine display in June if you prevent the snails eating the young plants. The plants should be thinned-out as soon as they are large enough to be handled.

WOOD ASHES FOR POTATOES (*Lex*).—You cannot have a better application for this crop. Sprinkle the ashes on the sets before covering them with soil. If used liberally the ashes will not only increase the weight of the crop, but the tubers will turn out cleaner than if they had no such dressing. A mixture of wood ashes and dry leaf soil is an excellent compost for placing in the drills with Potatoes.

DAISY (*E. G. H.*).—It is a form called by botanists "proliferous," and by gardeners "hen-and-chickens."

PRUNING ROSES (*J. P. T.*).—As you desire to defer the pruning of your Roses as long as possible, you may safely wait until the young growth on the extremities of the branches is an inch in length or even a little longer, and then cut the shoots back to the dormant buds at their base. The Golden Bicolor Geranium is very good, the leaves being round, of good substance, and the colours well defined.

GOLDEN FEATHER FOR CARPET BEDDING (*H. A. M.*).—It is too early to sow the seed in heat, as before the season is over the plants would grow much too large for your panels. We should not sow the seed before the 1st of April, and prick the plants out in the beds when large enough to be handled, of course having them hardened off so as to endure the exposure. In the London parks very small plants are planted an inch or two apart in the beds in May.

WHITE VERVUUS GERANIUM (*L. L. D.*).—This is undoubtedly a variety of great promise, and the best evidence of its merit is that a first-class certificate was awarded to it by the Royal Horticultural Society in December last. It was exhibited by Mr. Cannell, who possesses, we believe, the entire stock.

PLANTING RASPBERRIES (*T. Wilson*).—Raspberry canes may safely be removed and planted at the present time, taking care that the roots do not become dry during removal. We should cut the canes down to within 18 inches from the ground. By so doing you would only sacrifice a small quantity of fruit, while you would secure much better canes for bearing next year. You have been rightly informed that Carters' Prolific is an excellent variety.

ROSES FOR A SCREEN (*Clericus*).—We presume that you have a fence of some kind for forming the foundation of the proposed screen. In that case you will find a selection of Roses suitable for covering it in our "Notes on Villa and Suburban Gardening" in the present number.

DWARF BEAN FOR SMALL GARDEN (*Villa Gardener*).—The best dwarf variety for either a small or large garden is Beck's Gem. It is prolific, green when cooked, and of excellent flavour, but is not, perhaps, quite so productive and hardy as the Dwarf Fan.

LABELS FOR ROSES (*G. M.*).—The most permanent are thus described by Dr. Schomburgk:—"The labels are of sheet iron, and before painting them I employ first a mordant of the following composition:—One part of chloride of copper, one of nitrate of copper, and one of sal ammoniac are to be dissolved in sixty-four parts of water, to which solution is to be added one part of commercial hydrochloric acid. The iron or zinc labels are to be brushed over with this liquid, which gives them a darkish colour. In the course of twelve to twenty-four hours they become dry, and to their now dirty grey surface a coat or two of any oil colour will firmly adhere. Our labels are painted black, and when dry the names of the plants are written with white oil colour, and immediately sanded with fine white sand. The sand will dry with the white colour and become compact. The first labels prepared with this composition were written in 1871, and show not the slightest effects of the weather."

NAMES OF PLANTS (*T. W.*).—Physalis edulis, or Winter Cherry. The Fern had no spores. (*G. M.*).—3, Sedum coraleum; 4, Sedum alsoides variegatum. The Aloe is Aloe soccotrina, and the flower with coloured bracts is Dalechampia Roeliana. The numbers on the specimens having been displaced we are unable to reply in the usual manner.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE MANAGEMENT OF DOWN EWES AND LAMBS.

UNDER this heading we propose to consider the best system of management for producing early lambs from down ewes, the object being to feed both fat at the earliest period, and for that purpose we have the choice of several varieties of the down sheep. First, those bred in Somerset and Dorset, having their origin in a cross between the Sussex or South Down and the horned stock of the first-named counties. Some forty years ago an experiment was tried as to whether this cross breed could be reared so as to bring their lambs as early as the horned ewes. This, however,

failed; but large numbers of cross-bred stock remained, and upon which has been engrafted the Sussex down and latterly the Hampshire down, and in all those flocks which can trace their origin back to the horned stock the propensity to bring their lambs early with a large number of twins still exists. It is these ewes which we now buy out of Dorset, Somerset, and part of Wilts that we find drop their lambs in December and January. We can also purchase ewes of the Hampshire down breed at the July fairs which, when brought into the enclosed arable farms of the southern and eastern counties and well kept, will bring their lambs in January. The Sussex downs also purchased early will, under good treatment and high feeding, produce lambs in January; but they are not so well calculated for the purpose of early maturity as the two first-named varieties of down stock.

The method of feeding the ewes after purchase should be carried out with great care and attention, for a generous diet, plenty of good forcing grass, and cracked beans as trough food, are the best means of inducing the ewes to offer early to the ram. Yet after they are proved to be pregnant luxuriant feeding often proves injurious, causing loss both of ewes and lambs. We therefore advise that during any stage of pregnancy the ewes should be kept upon close bare keep with a change once a-day of better grass, but divided off by hurdle folding, similar to feeding off turnips; and in order to furnish keeping of this sort Italian ryegrass should be sown, one bushel per acre upon the young wheat in March, and harrowed in. This, if the best foreign seed is sown, will afford good pasturage immediately after harvest, or it may be hurdled off twice before Christmas and will give good lying for ewes and their young lambs. Down ewes, however, generally consume all the grass upon the farm, and often some roots and hay, before they lamb. We do not consider it a good plan to allow them to feed on the young clover seeds. These should be kept in reserve as a turn-out for the ewes and their young lambs for about ten or twelve days before they go together into the turnips. It is very desirable that this stock should have a dry sheltered foldyard for the lambing season. A shed 8 or 10 feet wide, enclosing two or three sides of a square, is best, and in a rather sloping position, so that the water may drain away quickly, and the bottom should be covered with earth or peat soil about 8 or 9 inches in depth. This will not only absorb the urine but will assist in keeping the fold dry. The fold should be littered over with straw, and a fresh supply continually added as cleanliness requires; sand also should be strewed over every other day. This serves to consolidate the bedding and prevent its heating, which is injurious to the sheep in various ways, and is often the cause of foot rot or epidemic lameness, which sheep have now been subject to for many years. A store of roots or cabbages should be made near the foldyard; the latter is preferable, particularly for ewes before lambing. We cannot advise the giving common turnips in this case, having known great losses of ewes from premature lambing after having been fed upon turnips; it must, however, be allowed that Swedish turnips are the safest food. The ewes should also have a run upon dry pasture or stubble land during the daytime, and when feeding upon roots they ought to receive a liberal allowance of good hay.

We will now refer to the treatment of the ewes when they have yeaned, and also of the lambs as they fall. The weather is generally very changeable, and is frequently accompanied by frost and snow, at the time of lambing. To be prepared for all contingencies it is well to have a store of the large Drumhead cabbages at hand, which are not so susceptible of frost as roots; they can be more easily eaten by the ewes, and will furnish a better supply of milk for the lambs than can be obtained when the ewes are fed upon roots. It will also prove very advantageous when convenient that a few acres of dry pasture or wheat stubble should be held in reserve, containing all the grass which might have grown upon it since Michaelmas, and upon this land, by keeping a shifting fold, they may at the same time receive roots in addition. This pasture will afford good lying for the young lambs as fast as they fall, so that they should with the ewes be

removed to it, and there remain until their removal to the turnips. This removal, however, should not take place until the lambs are strong enough to encounter the difficulties which usually attend open-field feeding, which they will generally be able to do at the age of two or three weeks.

The foregoing remarks must be considered to apply only to those lambs which come healthy and strong; but when the reverse is the case they should, together with twin lambs, which are usually more weakly, receive especial care and protection, being placed in separate apartments of hurdles, square under cover, until they are able to follow to the field. It should be carefully noticed which it is that requires treatment, it being sometimes the ewe, at other times the lamb, and often both. When the ewes are short of milk, linseed cake commonly used for feeding purposes should be broken fine, and with oatmeal mixed made into gruel. This may be given to them twice a-day in addition to the usual supply of food with great advantage, for although linseed meal may be preferable for the purpose, yet when required for a considerable number it would prove somewhat expensive.

Lambs in some seasons suffer much in health, and heavy losses often occur. There are two complaints to which young lambs are more particularly liable, and which at the same time often prove fatal—namely, the "white scour" and "rheumatic" affections. The first of these is often beyond control. We have sometimes cured, when discovered in good time, with a dose of ten drops of tincture of opium and half a teaspoonful of prepared chalk in half a wineglass of warm water. This is sufficient for a lamb at any age under one month, and should be repeated every three hours until the desired effect is produced. The rheumatic complaint is first discovered by the animal becoming crippled and losing the use of one or more legs, which swell at the joints, after which the lamb soon becomes emaciated, and in case actual death does not ensue they are profitless for keeping, and should be destroyed. This disease unlike the first-named, has no remedy, but in all disorders a preventive being better than a cure, we will show the causes and likeliest method of prevention. In our own flocks for many years we have suffered great loss from this complaint, and we consider the cause to be—firstly, the ewe having too much milk and more than the lamb can take; and secondly, the insufficiency of milk, whereby the lamb becomes unable to bear the effect of changeable and bad weather; and thirdly, undue exposure in low and wet situations. The first cause may be obviated by the milk being drawn from the udder every day in those cases where the lamb cannot take it all, for we believe this is the chief cause of the disease and often the occasion of the white scour, for by accumulation in the udder the milk becomes unwholesome. Insufficiency of milk may be in some measure rectified by the use of the before-named linseed gruel. The last cause named may be removed by keeping the stock on the driest and most sheltered parts of the farm or by artificial protection. The lambs having arrived at a fortnight old they should with the ewes be placed on root-feeding, and it ought at this juncture to be decided whether the ewes are to be fattened with the lambs or are to be held on for grass feeding and fattening in the summer.

(To be continued.)

WORK ON THE HOME FARM.

Horse labour will now consist of ploughing after turnips fed off by sheep and harrowing-in the wheat after the drill or seedman, as it is still in time to sow any variety of spring wheat. April wheat, however, being the best, it is wonderfully productive both of straw and grain. This also is a good time to plough and press land where the clovers may have failed, which land may be sown with either April wheat, beans, or peas, according to the nature of the soil. But instead of sowing the beans alone we prefer to add winter vetches or a few small maple peas, and we find it seldom happens that both crops fail; one or the other is sure to succeed, and oftentimes both. Another advantage in double-cropping is that it saves much hand-hoeing, for after being properly horse and hand-hoed the vetches or peas shake hands across the lines and effectually master the weeds. After being harvested the crops of pulse are very easily separated, beans being so much the larger. Some horses will still be engaged in carting newly threshed corn to market or mill, carting dung or soil, conveying gravel or stones to keep in repair the farm roads leading to and between fields and the gateways. Before, however, gravel or stones are laid on the roads men should be employed taking out the water tables at the sides and raising the centre in order that no water may lie thereon. We have often secured a good lot of useful earth in this way to store in heaps for use at the farm in various ways.

It is now getting rather late for drawing yard manure on to the clovers. At this time of year we prefer to dress with nitrate of soda, about 1½ to 2 cwt. per acre. This increases the clover crop, and at the same time the prospect for the succeeding wheat crop. Any increase in the weight of the clover roots we consider an increase of manure for wheat or any other crop which may succeed the clover.

Hand Labour.—Men will now be employed in preparing and sowing artificial manures, also corn or pulse, whichever may be

in season. Hedging and ditching will still be going on, also planting for fences. In the meadow land, where it is too moist for quickset fences, we can recommend the planting of osiers and withy stakes set in across each other like latticework. When these become strong they make a good fence against cattle, and the prunings pay well for cutting, being useful and sometimes very valuable to the basketmakers. The women may now be sometimes employed in pulling, preparing, and heaping turnips in the field beforehand in readiness for the sheep. Children, too, used to assist the women in this work, but they are now engaged at school; the women, however, at this work can earn good wages when paid by the acre, as they can do as much as men at such light work as pulling and trimming the roots ready for the cutter. If the weather is wet work should still be found for the women, such as mending sacks and other light work under cover, in order that they do not lose pay when the weather is adverse.

SEASONABLE FARM WORK.

THE first January number of "our Journal" this year was not read by me until the third week of that month. I have not read a new year's number that has given me so much pleasure since the one that contained the first article on "Our Vines" by "MAUD," when the Editors gave her and hers such a warm welcome to their columns. This time it is not the gardening or bee part that is so attractive to me, but the addition of our Home Farm. I hail with gladness its insertion, and wish it much success. Farming has been carried on during the past three years under very serious and great difficulties, so much so that many have had to succumb to the ill effects of bad times and worse seasons. Be that as it may, the home farm is a different affair. It generally belongs to the lord of the parish or squire of the neighbourhood, and let times come as they may, must be carried on. As the garden supplies its vegetables, fruits, and flowers to the establishment, so the farm affords its pork, beef, and mutton, each alike essential to the well-being of a large and well-ordered hall or manor-house.

First and foremost in all farming operations to be considered is the weather, and as January is the beginning of a year, so it is also said to be the key. The January of 1877 was mild and fine, but remarkable for its storms and gales of unusual violence. This year the weather began of the same spring-like character, but more mild and more genial, and the month closed with a week of frost, without the gales and storms that occurred last year. We have had no frozen-out gardeners soliciting our charity, and skaters have been the only malcontents to keep-up the grumble at the weather, which is an Englishman's privilege. Though the favourable January of last year did not produce anything very extraordinary in either garden fruits or on the farm, there is no rule why this favourable January should not be productive of a very favourable year.

We commence the year as we commence a "new farm," by preparing for the at-present-best-paying of all crops, that of barley. The land now is in fine condition for ploughing. As fast as the land is cleared it should be turned over to get pulverised by the frost that is sure to come ere March winds make it dry enough to prepare for sowing. All the land on which turnips have been and are growing about here is sown with barley, in the usual four-field course of husbandry. The production of a good crop of barley is paramount, and the preparation of the land for such now is of the utmost importance when it is well known that our best barleys are now making here 60s. to 52s. per qr. of 56 lbs. to the bushel, whilst barleys from strong, ill-drained, and badly farmed lands are selling at 82s.

Cattle and sheep now enjoy the mild temperature, and the ewes that are with lamb have all gone on the turnips, so that land will now be cleared and prepared apace. It is to be regretted that there is still in this and other counties good, strong, undrained lands that have not been sown with wheat, but I think that the proportion is smaller than usual this year. Now if there is any crop that pays on such land it is a crop of wheat, but time having now gone by for wheat-sowing, the preparation of such for barley must be next thought of. At present such land would not carry the horses without treading it too much, but what may be done with such land by a farmer with energy and foresight even in a bad season is wonderful. By biding the time and catching the proper dryness of the soil, even this kind of land has and will grow enormous crops of barley. How this is best done, and where another field or two of barley may be got, shall be the subject of a future half-hour's scribble.—RUSTICUS, Lincoln.

THE PRESENT ASPECT OF POULTRY SHOWING.

THERE are not wanting signs that the exhibition of poultry and Pigeons is at present not altogether on a satisfactory basis. The writer of our "New Year's Greeting" hinted at this, and at the probability of the lesser shows falling through and the monster exhibitions being alone continued. As we promised, in our article on "Poultry in the Past Year," we now proceed to go more fully into the subject.

We do not allude to the management of shows and care of the

birds while at them; for this, we think, has greatly improved of late from the immense rivalry between them; neither do we wish at present to enter into that very unpleasant subject, the growth of dishonourable practices in connection with them; but we propose to say something on the subject in its broadest and most general aspect. We have lately heard several of our greatest and most genuine fanciers talk of discontinuing exhibiting unless a regular reformation should take place in the system of shows, as believing that at present the general cultivation of poultry is not advanced by them. There is, indeed, no failing in their number, as anyone may see by referring to the often long list of those forthcoming in our own columns or those of our contemporaries. We have at times observed as many as six, and those not obscure shows, held simultaneously.

It is not uninteresting to recall the rise of a fancy which has grown to such gigantic dimensions. It is, we believe, not quite thirty-three years since the first English poultry show was held in the Regent's Park Gardens; four years later, in 1849, followed the first Birmingham show, at which the birds were exhibited in their own baskets; and three or four years later we had the great metropolitan shows in Baker Street, when the "mania" was at its height. Crowds flocked to them, and a general interest in poultry seemed for the first time to be aroused in the public, as anyone sufficiently curious may find by looking back to the leading articles at the time in the *Times* and other journals on the subject. It was natural that those who began to turn attention to the beauty of their poultry yards should delight in these opportunities of showing their favourites for comparison and of adding fresh specimens to their stocks. Great annual exhibitions were instituted in the great centres of life and industry, and lesser shows in many country towns. Everywhere in those early days these exhibitions were crowded, and the receipts at the doors were sometimes enormous. A large portion of the public had never seen some of the rarer and more curious fancy breeds, and were glad to give their half-crown or shilling to have a sight of them; in fact, the expenses of a show were generally defrayed by the money taken at the doors: hence committees could afford to give good prizes with low entry fees. The financial success of some shows became well known, others followed, and so arose this great multiplication of these meetings. So far much good was done; an occupation which might become a considerable branch of national industry was encouraged, and an innocent domestic amusement was shown to be not unremunerative. Now all this has somewhat changed. So common have poultry and Pigeon shows become that in many districts few people, save those actually interested in the exhibits, care to visit them, unless the exciting and, as we think, somewhat incongruous adjunct of cats be added; and even the novelty of this is wearing off. We have specially in our thoughts the admirably managed Bristol shows, where superb collections in an almost perfect building ceased to attract even a fair company. The result of this is, that finances from this source having failed, and committees have been obliged to look to other means of paying expenses, entry fees have become high and prizes small; and efforts have been made in various ways, not always quite creditable, to obtain the largest possible number of entries, such as soliciting earnestly for late entries in contravention of printed rules, consulting individuals about the prize list on condition of their sending large entries, &c. These clever schemes do not always succeed, and perhaps after having paid an entry fee of 7s. 6d. and won a 5s. prize an *ad misericordiam* appeal is received from the secretary stating that the committee are heavy losers, and trust that we shall for this time forego the 5s. prize and be content with the honour thereof; or more frequently some kind friends of the secretaries or committee write that they "are sure we would not wish Mr. — to be a loser by his spirited undertaking," no doubt in the hopes that should they ever stand in the same uncomfortable predicament the favour would be mutual.

The whole of these evils are, we consider, a sign of decadence in poultry shows arising from their absurd and uncalled-for multiplication. Unfortunately they are not all that we have to animadvert upon. Another glaring one has arisen from the same causes. Almost every local district or country show is being thrown open to the world in the hopes, often vain, of attracting more entries or more visitors. Beginners are discouraged at the discovery that it is perfectly useless to contend against some famous Crystal Palace or Birmingham winner sent to win the three-guinea champion cup (!) at their obscure village, and cease showing in disgust. The worst result, however, of this general throwing-open of shows is overshadowing. An excess of enthusiasm for the pastime and of desire for fame, combined with these too frequent opportunities of showing, have encouraged the sacrifice of many a beautiful bird, by being trashed about from show to show; and worse than this a whole class of exhibitors, unworthy of the name of fanciers, has arisen who seldom breed a bird, but buy them and knock them about from show to show as a regular commercial speculation, till they have paid their price several times over in prizes and remain decrepid and useless, and, if ever parents at all, are those of a sickly and degenerate produce. We should remember that showing is only a means to

an end, the means being the comparison of birds, and the end the improvement of their breeds. If the end is sacrificed to the means they become worse than useless.

The aforesaid difficulties in the question of finance have brought about harm in another way—viz., the exclusion of all save "paying classes"—i.e., from the difficulty of making both ends meet. When a schedule is to be drawn up the catalogue of last year is referred to, and those classes which have not been well filled are forthwith cut out, and the breed is relegated to the "any variety class." Many interesting kinds have hence become almost extinct.

To sum up our observations, the indiscriminate increase of shows has worked evil in two directions, firstly in causing many doubtful expedients to be resorted to, to prop up undertakings with financially unsound footings; and secondly, in inducing an excessive and mischievous showing of birds to their detriment. We shall endeavour in another article to point out broadly what to us seem the best means of remedying these evils.—C.

PONTARDULAIS SHOW OF POULTRY, &c.

THIS was held January 30th and 31st, when the following prizes were awarded:—

POULTRY.—DORKINGS.—1, R. Leyshon. 2, The South Wales Live Stock Co. 3, J. Milward. SPANISH, MINORCAS, LEGHORNS, &c.—1, J. Kitchen. 2, M. E. Williams. 3, The South Wales Live Stock Co. GAME.—Black or Brown Red.—1, R. Thomas. 2, J. Phillip. 3, J. P. James. Any other variety.—1, J. Andrey. 2, The South Wales Live Stock Co. 3, R. E. COCHINS.—1 and Cup, C. Bloodworth. 2, A. W. E. Darby. 3, E. Clatworthy. *etc.* T. A. Dean. E. Clatworthy. HAMBURGS.—Silver or Golden-spangled.—1, 2, and *etc.* The South Wales Live Stock Co. 3, C. Pearce. Any other variety.—1 and 3, The South Wales Live Stock Co. 2, H. Hopkins. POLANDS.—1, The South Wales Live Stock Co. 2, Dr. E. Lloyd. 3, A. W. E. Darby. BRAHMA.—Dark.—1, E. Pritchard. 2, S. W. Thomas. Light.—1, T. A. Dean. 2, A. W. E. Darby. 3, The South Wales Live Stock Co. 4, P. SEAGUS.—1, Dr. E. Lloyd. 2 and 3, The South Wales Live Stock Co. BANTAMS.—Game.—1, C. Martin. 2, E. H. Gould. 3, A. J. Morris. Any other variety.—1, E. Pritchard. 2, T. C. Temple. 3, T. F. Phelps. MALAYS.—1, The South Wales Live Stock Co. 2, J. C. Huxtable. DUCKS.—Aylesbury.—1, S. R. Harris. 2, R. K. Penson. 3, C. E. Waring. R. K. Penson. *Romans.*—1 and 3, R. K. Penson. 2, T. F. Phelps. ANY OTHER VARIETY.—1, S. W. Thomas. 2, R. K. Penson. SELLING CLASSES.—1, C. Bloodworth. 2, The South Wales Live Stock Co. 3, Miss T. T. Nightingale. Cock.—1, E. Clatworthy. 2, J. H. Nichols. 3, C. Bloodworth. *Hens.*—1, T. Jarman. 2 and 3, The South Wales Live Stock Co.

PIGEONS.—CARRIERS.—1, T. Weeks. 2, J. E. Butler. 3, H. Yardley. POUTERS.—1, G. Holloway. 2, R. Pike. 3, M. R. Borland. TUMBLERS.—1 and 2, H. Yardley. 3, Mrs. Primavesi. ANTWERPS.—1 and 3, H. Yardley. 2, W. S. Handford. *etc.* J. Weaver. JACOBIANS.—1, H. Yardley. 2, T. S. Phelps. 3, Mrs. Primavesi. FANTAILS.—1, J. F. Loveridge. 2, P. R. Spencer. 3, Miss T. T. Nightingale. BARBES.—1, J. H. Jones. 2, P. H. Jones. 3, M. R. Borland. TURBITS.—1, H. Yardley. 2, C. Parsons. 3, J. F. Harvey. OWLS.—1, J. F. Harvey. 2 and *etc.* P. H. Jones. 3, H. Yardley. NUNS.—1 and 2, J. F. Harvey. 3, M. R. Borland. MAGPIES.—1, F. P. Bulley. 2 and 3, J. F. Harvey. ANY OTHER VARIETY.—1, P. R. Spencer. 2, A. C. Phillips. TUMBLERS.—Not less than Six High-Flying.—1, H. W. Evans. 2, W. Lewis. 3, Mrs. Primavesi. SELLING CLASS.—1, J. E. Butler. 2, J. F. Harvey. 3, R. Pike.

JUDGE.—Mr. M. Leno.

READING PIGEON AND CAGE BIRD SHOW.

THE Reading Show has become a regular institution, to which we look forward with much pleasure. So admirably adapted to the purpose is the Corn Exchange, and so excellent has the management of the Show always been, that this the fourth Exhibition secured nearly 1200 entries, many of the classes being unusually good. Mr. Lang's pens were empty owing to a mistake of the date.

In Pigeons Carriers headed the list with four classes and forty-eight entries. The first Black cock is a splendid bird, with singularly good beak-wattle and fine form; we do not recognise having seen the bird before. Second a Black, which we have often seen in the prize list; rather bow-legged. Third a Dun. We much admired the first Black hen for her fine wattle. In the Any other variety of cocks Blues were first and second, and a White third, while the winning hens were all Blues. Dragoons had five classes and numbered seventy-eight. We thought the first Blue cock singularly good all round, especially in eye. The first Silver and second Blue hen, too, were far ahead of the rest of their class. In Reds and Yellows a capital Red cock was first, and a most beautiful Yellow hen took the cup. Mr. Woodman's first Blue Chequer was a good bird of his kind. Antwerps were legion. We cannot attempt to criticise the Homing birds. In the Short-faced class all the prizes went to fair Red Chequers. Pouters had five classes fairly filled. The cup went to Mr. Baker's Black hen. This struck us as a good award, for she is a splendid bird of immense length and limb. The same exhibitor's Blue cock was first in its class. Tumblers.—Almonds were a capital class; in an entry of only nine an extra third prize was awarded. Light Agates were first and second, and a Kite third, in the Any other variety of Short-faced. A Yellow Rosewing and a Black Ball were first and second in the Flying class. Owls.—Foreign were fair; first and third Whites, second a Black. In the English class for Blue or Silver a magnificent Blue very good in beak was first. We liked Mr. Bulton's very highly commended Blue, which is very rich in colour. In the Any other variety class Powdered Silvers were first and second. We certainly cannot see sufficient difference in this sub-variety to warrant its being entered in a separate class to the former. Third a Yellow. Turbites.—Blue or Silver cocks.—First a small Silver, second a well-known old Silver, third another

Silver, small; we did not quite like its peak. Any other variety, cock.—First-and-cup Mr. Burnell's little Owl-like Yellow; second a very attractive little Red, third a good Red. Hens.—First the Birmingham cup Yellow, second a pretty Silver, third a Blue, rather long in beak. There were other good birds in the class. Magpies.—Blacks were a fine class of fifteen; of course the prizes went to Oxford. In the other class a Yellow was first, Reds being second and third. Archangels were not good; the first-prize-bird was lame, and with almost a shell crest; a Black bird, which we thought should have been in the variety class, was third. Jacobins.—The first Red is a wonderful bird with very fine chain; second a Yellow of the old-fashioned type without mane. The cup went to a beautiful little White, second and third being Blacks. Barbe.—First-and-cup a singularly good Red; second a Black, which we admired for its smallness, for the prevailing fault in the birds now shown is coarseness; third a Black in fine condition. Fantails.—A good flat-tailed bird, with tail coming well down at the sides, in fact when looked at from behind almost a perfect circle; second the pretty little cup hen at both the Palaces; third a large bird with fine motion. Any other variety.—First a Yellow-Swallow, second a Frillback, third a Blue Priest. Mr. Tegetmeyer showed a pretty Pigmy Pouter, which was labelled "wrong class," why we could not understand. Five local classes followed, containing many creditable specimens. We thoroughly approve of this encouragement to local beginners in the fancy.

The *Cage Birds* were a marvellous collection. Canaries had twenty-four open classes and ten amateur classes. In the former, though the classification was so extended, the entries averaged only five to a class, and nine classes were empty. In the latter the entries averaged over seventeen a class. Every variety was well represented, and all looked well and happy in the pleasant temperature of the building. British birds had four well-filled classes, and the three classes for foreign birds were about the best we ever saw. Among the most beautiful exhibits were Mr. Goddard's pair of Pennant's Parakeets, Mrs. Monck's collection of small birds, and the same lady's Merle; resplendent Pekin Robins, Turaco and Harlequin Doves, also Mr. Williams' "Green Leeks," and Mrs. Skurray's pair of Rosellas.

The Committee are to be heartily congratulated on the success of their Show, which attracted a large number of visitors.

The Judges were for Carriers, Pouters, Jacobins, and Owls, Captain Norman Hill; for the rest of the Pigeon classes, Mr. F. Esquilant. For *Cage Birds* Mr. W. A. Blakston.

LOP RABBIT BREEDING FOR COLOUR.

We shall now speak of Lop breeding as it should be carried on, so as to improve the Rabbits' strength and beauty.

Age is important in breeders, as we have already pointed out. When extra excellence is sought after a little more time should be allowed, and the extra expense will be easily recouped. Another important precaution is the prevention of connection between blood relations; cousins even when once removed should not be connected. Size is important in the Lops, and if this suggestion is not seen to young ones of a diminutive type are likely to be the result. Another undesirable effect of in-breeding is causing any hereditary disease to be doubly or trebly represented. A third objection is in the colour, which is the more immediate subject now under notice.

The effect on the colour is always very apparent. It lightens the shade and causes streaks and spots which are not proper; in fact, if the practice be continued a motley colour results, as may be seen in many small country collections where no fresh blood is ever introduced. Some fanciers are so proud of their stock that they do not like to introduce any inferior blood. They would, however, find that a change would be most useful.

Another source of deterioration is a false economy in the number of bucks kept. In poultry a cock is kept for a certain number of hens, but in Rabbits one buck is made to serve almost any number of does, the result being that abortions are frequent, and the young are weak and sickly, and especially bad in colour.

To produce the different colours to perfection is a difficult but withal pleasing task. Experience is the best guide as to how to obtain certain colours, and how to ascertain what colour the litter will be. Lovers of variety, whose name is legion, often put a doe of one colour to two bucks of distinct colours, in the hope of getting a great variety of colour in the resulting litter. Sometimes the young take after the two sires, but more often after only one. A litter is seldom all of one colour, unless the sire and dam were alike, or unless they were bred in-and-in to a great extent. Sometimes the colour of the mother predominates, and very frequently that of the father. In breeding for colour in Lops it is important, therefore, to select healthy and well-developed Rabbits for parents, and to constantly introduce strange blood. At the same time the sire should not be allowed to serve too many does—not more than six or eight, and should not visit a doe more than twice a week.

Grey almost invariably produces grey. If two grey Lops are paired the issue will be likely to be all of that very undesirable colour, with a little white perhaps, and a few white blotches if

the parents were blood relations. If it so happens that they are not from a grey stock a variable litter may be had, but it is not usual. A grey buck and grey-and-white doe will produce a similar result, though the grey will be of a bad shade. A grey-and-black will produce dark greys and poor blacks unless the stock is a light one, when good black-and-whites may sometimes be expected. It is not advisable to keep a grey buck, as very few of the combinations that can be managed with it are particularly good, and the colour is a very hard one to get rid of. Grey-and-fawn gives dark fawns and poor greys. Black-and-fawn gives very dark fawns, some good browns, and occasionally a tortoiseshell. The latter are not very common for the combination, and the colours are generally very intense, producing a handsome and valuable Rabbit. Blue and black are bad combinations, and mostly throw very dark blues. Blue and fawn may produce a poor tortoiseshell, or the colours may be mottled—a very ungainly look. Sooty fawns interbred throw good sooties and dark fawns. Black and black-and-white will produce a litter mostly the colour of the latter, and dark or light according to the shade of the parents. Fawn-and-white and black-and-white crossed will sometimes result in good tortoiseshells, but generally light. Fawns crossed together cause both colours to deteriorate. Blacks crossed together breed very true.

The larger-made and most healthy parent often has the most influence upon the offspring, and this fact should be borne in mind in crossing. Some does cannot be relied on for breeding, since they seldom, if ever, have any young the same colour as themselves. These should be avoided if possible.—G.F.A.

VARIETIES.

WE have before us the schedule of the great *Cage Bird Show* to be held at the Alexandra Palace from the 9th to the 15th inst. It is a most complete one, with thirty-three classes for canaries, twelve for mules, ten for British birds, one for migratory birds, and no less than fifteen for foreign birds. The Judges are for British and foreign birds Messrs. Harrison Weir and Jenner Weir; and for canaries Messrs. J. Calvert and R. L. Wallace. Mr. F. W. Wilson is Secretary of the Show.

WE understand that the provisional Committee of the Poultry Club is soon going to meet to elect the original members. Mr. Cresswell has forms of request for election, and will be happy to forward them to all applicants. It will be a convenience to the Committee if all who wish to join will at once send in their names, so that they may be elected at the first meeting.

THE East of Scotland Bee-keepers' Society will hold its third annual Exhibition of bees, honey, hives, &c., in connection with the Horticultural Society's Exhibition on the 5th, 6th, and 7th of September. The prizes, which are open to all, amount to upwards of £40.

THE total number of agricultural newspapers published in the United States in 1860 was 4051, in 1870, 5871. The number of copies annually issued increased more than 50 per cent. from 1860 to 1870, and the growth of wheat increased in much the same proportion, having been a little more than 173,000,000 bushels in 1860, and more than 287,000,000 bushels in 1870. The value of real property increased 40 per cent. in the same period; and so extremely sensitive is the newspaper barometer that whenever the number in circulation of agricultural journals increases in any particular State you may be sure that the area of cultivated land, the amount of produce sent to market, the value of each farm, and the wealth of each farmer, has increased in the same proportion.—(*Agricultural Gazette*.)

THE *Times* says that many hop planters in Kent have grubbed a portion of their hop gardens. The increased cost of cultivating the crop and the comparative low rate realised for last year's produce consequent on the large importation of foreign hops are the reasons alleged for this step being taken.

WE have received a copy of Piper's "*Poultry-yard Account Book*," published by Messrs. Groombridge & Sons. It is so arranged that the following statistics will be able to be determined:—The number of eggs laid daily, the total amount received for produce of eggs, fowls, and chickens sold, the value of feathers and manure, the number of eggs and fowls used in the household, the amount of expenditure, the number of hens set, the dates of setting, the number of eggs, the dates when due, the number of chickens hatched, and the number of chickens reared, a balance sheet at the end determining whether the transactions of the yard have been carried out at a profit or loss. It will prove a very useful aid to poultry-keepers.

AN experienced agriculturist has written as follows on stock and pasturage:—"If the pasturage is not good it is vain to think of keeping stock of enormous size, unless most of the work is to be done at the manger or crib. The pure Alderney is much esteemed as a butter cow, as everybody knows, by small holders, but they are bad indeed to sell if barren. They look poor outside when they are quite fat within; and a butcher who is trying to purchase will expatiate freely on the lean appearance of the beast,

knowing full well all the time that, to use a butcher's phrase, "she will die well." A cross, of which nearly half is Alderney, will in general, as I think, be found the best; but when we get towards the Welsh borders the Welsh blood may fairly take the place of the Alderneys; and towards the borders of Scotland there are the Ayrshires and other very good breeds; as for the south, who has not heard of the fame of the Dorset butter cows?"

— REGARDING the breed as a whole the superiority in value of the short-horn above all other good beef breeds (and in these islands we have several deserving this character) depends upon maintaining unimpaired its old reputation for combining a tendency to milk in the females and rapid growth in the young of both sexes with sound constitution and a readiness to adapt itself to local peculiarities of soil and climate. No other breed has ever shown the adaptability which the short-horn has. It is not merely that it has forced its way into every breeding district in the three kingdoms, but the colonial and foreign agricultural records tell the same story.—(Field.)

BAR-FRAMED HIVES AND THEIR MANAGEMENT.

NO. 3.

PERHAPS the best mode of carrying on my treatment of this method of managing bees, which is now so popular among all the leading intelligent bee-keepers of the old and new worlds, will be by describing the order of proceeding which may be imagined as taking place in a well-worked apiary on this principle.

Let us begin with the early operations of the year and follow a master in the management of his bar-framed hives. First of all, however careful he may have been to see that all his hives were in good condition before winter—well fed, well provisioned, well protected against wind and damp and snow—he well knows that no two winters are alike. A long frost will keep his bees in close quarters, during which shelter and absolute repose are all that he can provide, and these will bestead him well; but he must be on the alert as soon as more genial weather comes, taking care that the bees have every facility for removing their dead, of which many will be found, sometimes in heaps, lying on the floor-board. He will materially assist his bees and promote their health if he can sweep the boards of all dead carcasses and scraps of wax, which fall from the cells in quantities as the bees open them to get at the honey. In the case of bar-framed hives it is well to set them in the late autumn over a temporary shallow box open at top with a drawer to it, which may be cleansed at pleasure. In this case the floor-board of summer use will have to be removed, so that all offal of every kind may drop directly into the drawer. This drawer, too, will be found very useful for feeding both in the late autumn and in early spring, whenever it is necessary to give supplies of food in larger or in smaller quantities. For here is another peril which may present itself as in unusually warm winters like the present. In such seasons the bees will generally remove their dead from week to week if not from day to day; but in so doing, and in all the increased activity of such a genial time, the consumption of food will be enormously increased. Already, even before Christmas, have we heard voices of tribulation because of hives that have perished of starvation. What may we not expect in the next few months when the bees have been stimulated into early breeding, with which comes always an enormous pressure upon their stores? The eke-like drawer which I describe will be found especially useful now. The best way of using it as a feeder is to place a piece of sound comb flat at the bottom, and to fill this from time to time with syrup or honey as required. In the case of straw hives it may of course be used, only there will be need of careful watching lest the bees should in autumn or in spring commence lengthening their combs downwards, which they will often do. The wooden base of the bar-frame will of course check this tendency. In early autumn I prefer feeding from the top of the hive, but at a later period or in early spring bees take food more readily in the way now indicated, as they must perforce descend to go out of doors. A little fresh food will be very tempting to them here. Indeed I have never examined combs so placed for feeding without seeing bees quietly feeding; whereas in other cases, when feeding by bottle at top, no food has been perceptibly taken down. Cared for and stimulated gently in this way, even where there may be a sufficiency of food in a hive, its population with a good queen will survive well all the perils of winter and should be found in a highly prosperous condition in April or May.

But before this time another care occupies the bar-framer. I allude to his anxiety that the combs in his hives shall be all in good condition, with no excess of drone comb, and with all his combs well arranged as well for breeding as for honey storage; and here his advantage over the straw-skepiot of olden days is enormous. The latter, poor fellow, has no opportunity for proper examination of his hive. There may be a large excess of drone comb, and this may be situated in the worst possible part of the hive. I have known instances of several such combs containing many thousand cells alternating with and surrounding the worker brood cells in such excess that the queen was confined for weeks

to a very narrowed space, until the slow growth of the population enabled her to lay and rear brood in remoter combs, while tempting her to lay an excess of drone eggs out of all proportion to the wants of the hive. This is no uncommon occurrence. The bar-framist, on the other hand, has no such danger to cope with. Choosing a still, warm day when the bees are most active he proceeds to examine his hives. Comb after comb is taken out of each hive. It is carefully examined. The replacement is judiciously made. Cutting out all mildewed, old, or defective pieces, he arranges the combs according to circumstances. If need be, as I myself often do, he will carefully drop into the emptied honey cells here and there (not where breeding is going on) a few ounces of food, taking care to avoid messing the combs or dropping the syrup about. Should it be necessary he will sacrifice a hive which appears too weak (should such be in his apiary) to be likely to do well, and utilise its combs by substituting one here and another there, in this hive and in that, to replace drone with worker combs or *vice versa*, or old and defective combs with such as are whole and fresh. In this way two strong hives can be made out of three or more weak hives, the populations being united and the brood comb added also. Nothing of this sort is possible to the straw-skepiot. Having gone thus carefully through the apiary and put all straight again he looks forward patiently and hopefully to the future, knowing exactly the condition of his apiary, and having made the best provision for all eventualities.—B. & W.

OUR LETTER BOX.

EGGS ILL-FLAVOURED (E. H.).—Wherever eggs have an unpleasant and unnatural taste it arises from one of two causes—either the food on which the fowls are fed, or the substance on which the eggs are laid. This may be easily tested by shutting up a laying hen and giving her garlic or matted barley to eat. In a few days the eggs will taste of the food. We have tried this ourselves, and know it to be correct. Another theory is, but we cannot speak of it with the same certainty, that an egg laid on any strong-smelling substance will contract it. This is explained by the fact that the shell when the egg is first laid is comparatively soft and impressionable, and only hard after contact with the atmosphere. Let your birds be wholesomely fed on plain food and your nests be made with clean straw. Hay nests have a tendency to make eggs taste. Follow nature, and you will have nothing to complain of.

PARROT SELF-PLUCKED (J. C.).—Let it have a tepid bath daily. If the bird will not bathe pour the tepid water over it through the rose of a watering pot.

BOOK (A. Gregory).—Write to Mr. Pettigrew, Priory Vineyard, Sale, Cheshire.

REMARKS.

30th.—Thick white frost; a little snow about 7.40 A.M., fine with sunshine at 9.30 A.M., misty after 4 P.M., but starlight night.

31st.—White frost in morning, bright sunny day with snow-like clouds at intervals; cloudy night.

1st.—Clear cold morning, sunny day, very fine night; stars bright.

2nd.—Damp morning and warmer, a little rain between 9 and 11 A.M., sun-
shine between 1 and 3 P.M.; slight rain again in evening.

3rd.—Dull day, damp evening, and cloudy night.

4th.—Almost constantly overcast, damp, and dull.

5th.—Dull day; very dark from 10 A.M. to 1 P.M., and no sun all day.

Barometer very high, with northerly but very slight wind, and moderate frost in the early part of the week.—G. J. SYMONS.

COVENT GARDEN MARKET.—FEBRUARY 6.

We have no alteration to make from last week.

From observations taken near London during forty-three years, the average day temperature of the week is 45.9°; and its night temperature 31.0°.

PRUNING FRUIT TREES.

ON page 111 "A PLAIN GARDENER," has made a plain statement, and an important one. Unquestionably many fruit trees have been greatly benefited by the pruning to which they have been subjected during winter; but, on the other hand, others have about as certainly been rendered less fruitful by the free and ill-considered application of the knife to their branches.

Pruning must be conducted in accordance not only with the habits of the trees, but also in accordance with the nature of the soil in which they are growing. It has been said that if summer-pruning is intelligently performed that little remains to be done in winter, which is true; and it is equally true that the pruning of trees in summer is more effectual in the production of fruit than cutting them severely in winter. Yet although this has been demonstrated over and over again and the fact became public property many years ago, there remains still a considerable amount of pruning to be done during the winter months.

Not infrequently we find that trees have been neglected for one or more years, and usually the longer they have been neglected the more severe is the pruning to which they are subjected, as if to compensate for past neglect. That is a common practice, and it may be added a common mistake. The extreme mutilation of trees during the winter is not promotive of fruitfulness. If the trees have been long neglected, be they Apple trees or Gooseberry bushes, the sudden and violent "opening out of their centres" is seldom satisfactory. The time for benefiting the trees by exposing the branches in their interior has passed if the pruning has been deferred until long after those branches have become leafless and spurless. Such wood cannot be made fruitful, and the only result of such pruning is a mass of young sappy shoots growing where the sun cannot shine on their leaves nor the air circulate freely to render the wood fruitful.

As a rule, standard and bush fruit trees which have been permitted to grow in a natural and semi-wild state had better remain so, and continue bearing on the extremities of their branches until better fruit can be obtained from young and better managed trees. If any pruning is done to such trees it should be limited to a moderate thinning-out of the branches, severing them as close as possible to the main stems; for if the branches are simply shortened the growth in two years will be more crowded than ever, and the result will be more leaves but less fruit than before.

Your correspondent has, however, alluded to the excessive pruning to which young trees are often subjected, and has adduced evidence that a more natural system of growth possesses advantages where large crops of fruit are the main object in view. By rigid summer-pinching and root-pruning a tree can be brought into a bearing state and be made to form a mass of fruit spurs before it has attained a height of 3 feet. But of what real use is that tree? In certain positions such trees are ornamental, but the most that can be said about them is that they are cultivated toys—gardeners'

No. 861.—VOL. XXXIV, NEW SERIES.

and amateurs' playthings. For practical usefulness and for yielding a substantial supply of fruit they are of small value in comparison with trees that have not been crippled by the "skill" of man. Trees managed on the violent restrictive principle alluded to are at ten years of age of no greater value than they were when at five or six years old, and at twenty years old what are they? Answer, Dead or dying. If owners of gardens desire to have the Japanese style carried out because of a certain amount of pleasure it gives they have of course a perfect right to that form of gratification; but do not let the system be misnamed a "profitable mode of fruit culture," because hundreds of "plain gardeners" know that it is not profitable.

Another plan of managing dwarf trees that is perhaps more common than that above noticed is only a few degrees less profitable. This is the system that appears to be alluded to by your correspondent. It is somewhat as follows: Dwarf trees are purchased that are intended to be grown on the summer-pinching principle, but not on the root-pruning system. They are intended to be moderately dwarf and healthy, not extremely dwarf and unhealthy. The idea is good, but is not always carried out properly. So far as the roots are concerned the prescribed rule of culture is adhered to, for they are left unchecked, but the summer-pinching is not thorough nor persistently conducted. For the first year or two when the trees are new and small they are "gone over" with tolerable regularity; but as they grow larger the novelty of the system wears off, and other work presses so hardly that the necessary pinching is not, indeed cannot, be done, and nearly all the pruning is left until winter. The trees are then pruned severely, and properly so far as their shape is concerned. The branches are disposed regularly and thinly, and after the work has been done the trees have a professional business-like look. A "lot of stuff" has been taken out and preserved for flower stakes, and the work is viewed with a complacent half hopeful yet half doubtful feeling that finds expression in a subdued observation that "they ought to do something." And they will do something—they will grow another fine crop of flower stakes.

If the soil is good and the roots are unchecked young fruit trees that receive little or no summer-pinching form long and strong growths, each shoot being from 2 to 4 feet long. With the object of imparting to the trees an agreeable shape, which in itself is commendable, and also with the object of forming fruit spurs, which is again commendable, the breast-wood is cut closely in and the extremities are very much shortened. The object is good, but the mode of attaining it is erroneous. A tree thus operated upon cannot form fruit spurs. The "art" of the pruner and cultivator renders that impossible. The system is in its nature fatal to the formation of fruit buds. They cannot form, for neither time is afforded nor material provided for the accomplishment of this desirable object. In cutting out the flower stakes the fruit-bud-forming material is removed, and time is lost in the trees attempting to provide another supply for that purpose by another season's growth. It is man warring against Nature, and both are losers.

Having, as a plain man, "laid down the law" in a plain

No. 533.—VOL. LIX, OLD SERIES.

way, I can fancy some such question as the following being asked, with an air of doubt if not of something more :—"Do you mean to say that the long shoots ought not to be removed, and that if they remain they will form fruit spurs?" I have not framed that question so that it is easy to answer, nor in a form that I would prefer; but have put it as a natural question, even if difficult to reply to categorically.

I will answer the latter part of the question first by saying that if the long shoots are permitted to remain they will form fruit spurs, provided—and this is an all-important condition—that they are so thinly dispersed that the sun and air can act on every leaf. Natural spurs will then form the whole length of the shoots. It will take two years, or it may be three, for the fruit buds to thus form; but form on Apples, Pears, Plums, and Cherries they will, and after that there will be little trouble given by breastwood. The flower-stake-growing period will have passed, and the blossoming and (weather permitting) fruit-bearing era will have arrived. If man will just aid Nature by thinning-out superfluous shoots and prevent others forming in their places the branches left will become clothed with fruit spurs, but if he fights her by cutting off in winter nine-tenths of the growth formed in summer (which is often the case) he will have to wait a long time for fruit. To the former part of the question, as to whether the shoots ought to remain, the answer is "No. It is by man's error that the thicket is produced, and the error must be repaired to give Nature a chance to do her work." The lost balance between root and branch must be restored. Such growths that impede the ingress of air to the tree and obstruct the action of light on the foliage must be removed, and further obstruction must also be arrested at its source—the roots. The roots must be partially checked, or the tree must be wholly dug up and replanted according to its size and vigour, and fruitfulness will ensue.

Trees which have received little or no pruning since they left the nursery grow naturally thinly, but not always symmetrically, and in time become studded with natural spurs and laden with fruit. Where quantity of fruit is of greater moment than the shape of a tree it will be well to only prune the tree very slightly after it is five years old, but merely thin out branches that are likely to cross each other or cause overcrowding. If a symmetrical tree is of importance then it must be pruned accordingly, but the roots must have attention as well as the branches, or fruit will be sparse. As many examples prove, trees both handsome in shape and fruitful in nature may be produced by an intelligent system of manipulation, but this can only be accomplished by preventing the power of the roots overbalancing that of the branches, while at the same time root-action is sufficient to sustain the tree in a healthy state.

The extremes of severe restriction on the one hand and natural wildness on the other have been pointed out, and it is for the cultivator to adopt the mean that will best meet his requirements, but if fruit is the main object let him put much trust in Nature.—A MIDLAND COUNTIES FRUIT-GROWER.

VEGETABLE CULTURE.

CHAP. VII.—CABBAGE AND KALE.

THE Cabbage is found growing wild in many parts of the Continent and in several counties in England. It is one of the most common vegetables, and so easily and generally cultivated that we will only briefly refer to it here. With a little attention and forethought Cabbages may be had fit for use every week in the year. To secure this a small patch of seed should be sown the first or second week in August. The plants from this will be ready for planting by the latter end of September or beginning of October. The ground on which they are to be planted should be deeply dug and well manured. The plants should be planted 18 inches apart. It is an advantage when they become established before winter sets in, and when they do this a little soil should be drawn to their stems. During the winter they require no attention unless the ground becomes sufficiently dry for the Dutch hoe to be run through it. At all events this should be done as early and as often as possible.

In cutting the heads nothing but the centre should be taken, leaving as much of the stem as possible, and in the course of a few weeks these stems emit shoots, which form capital little heads equal in quality and more in quantity than the first produce. This is a most profitable way of dealing with Cabbages. From one piece of ground we always cut from May to December.

The first spring sowing should be made along with the Brussels Sprouts. The plants from this sowing will furnish heads in July and August, and if cut then will supply sprouts well into spring. Another sowing in April or May will furnish plants to complete the circle of the year with Cabbages.

Caterpillars are often most destructive of Cabbages. We have tried many ways of destroying them, and have found that picking them off before they have time to do any harm to be the only satisfactory remedy. This may appear a tedious way of dealing with them, but it is not, and if taken in time it is both economical and efficient.

A vegetable called the Portugal Cabbage is not much cultivated, yet nevertheless it is of considerable merit. It is not so hardy as the common Cabbage, and to grow it properly the seed should be sown and the plants raised in a frame. The midribs of the largest leaves may be cooked and used as a substitute for Seakale.

Enfield Market is the most useful variety in cultivation. Early York is nearly as good, but not so large; Little Pixie, Nonpareil, and Beck's Premier are also good. Red Dutch is cultivated like the others, but only used for pickling.

SAVOYS.

The Savoy resembles the Cabbage in many respects, especially in form of growth. It is cultivated chiefly for autumn and winter use. For a long succession the seed should be sown three times in spring—towards the end of February, the end of March, and the end of April. The earliest plants will be ready for planting in May, and the last in July or early in August. In localities where the winters are severe a good quantity of Savoys should be grown, as they are very hardy and not only endure frost well but frost improves their flavour. Little Wonder and Early Elm are two dwarf-growing good sorts, which may be planted 15 inches apart. Green Curled, Green Globe, and Drumhead are also excellent kinds, but they grow larger.

BORECOLE OR KALE.

Like the preceding this is a first-rate winter vegetable which is not injured by the most severe weather. It is a favourite vegetable in Scotland generally, but especially in the north, where we can remember seeing it in many amateurs' gardens as the only "winter green." The first sowing may be made about the last week in March, and the last sowing a month or six weeks later. Sow thinly, and treat the young plants in the same way as the other Brassicas. In planting Kale, however, the strongest and richest piece of soil in the garden should be selected.

The dwarf-growing sorts are more satisfactory than the tall ones. Cottagers' Kale is an extra hardy sort. Asparagus Kale is worth growing on account of the resemblance it has in taste to that vegetable. As a generally useful Kale none excels the Dwarf Green Curled.—A KITCHEN GARDENER.

DIPLADENIAS.

A FEW remarks on the culture of Dipladenias may not be inopportune at this season of the year. Dipladenias should be in every collection of stove plants; their beautiful flowers are so valuable for cutting purposes, and the plants are indispensable for exhibition, and are equally valuable for home decoration. They are propagated from seed and cuttings, the latter plan being most generally adopted. For cuttings use a mixture of peat, loam, and sand, with a little broken pot dust, and place the pots containing the cuttings in a bottom heat of about 80°. After the cuttings are rooted pot them off into small thumb pots, and subsequently into 48-sized pots, when they will require to have three or four small stakes, to which the young growths can be trained. Afterwards shift the plants into 24-sized pots, and again into larger pots as required. A balloon trellis is necessary, to which the shoots can be trained for blooming.

This is a good time to pot, clean, and tie plants that have been at rest during the past four months. Employ light fibrous loam and peat, with a good mixture of sharp silver sand and dust of broken pots, the whole being well mixed together; pot pretty firmly, and place the plants in a stove with a minimum temperature of 60°; syringe the plants lightly every morning, and in a few days they will commence breaking, and in the course of a week or ten days they will have growths from 6 inches to a foot long. They will now require strings from 6 to 8 feet long according to the size of the plants, to which the growths can be trained. Secure a cord

crossways of the rafters and lights at the top and bottom, and from these stretch other strings in an upright direction, and at a distance of from 4 to 6 inches apart according to room. By the end of May the plants will have grown to the top and will have commenced ripening their young wood, and shortly afterwards will commence showing their flower trusses, which will have from four to six flowers on each. The growths must then be carefully removed from the strings and be arranged on the balloon trellis, bringing the growths round so as to place the trusses of flowers where they can be best seen. They will continue in flower for two or three months, and produce a grand display. Give the plants a little weak liquid manure three times a week during the flowering period. About September withhold the liquid manure, and gradually cease watering preparatory to resting the plants for the winter.

The most useful are *Dipladenia amabilis*, *D. amœna*, *D. Brearleyana*, *D. hybrida*, *D. insignis*, and *D. splendens*. There are other new and old varieties which anyone can select from a nurseryman's catalogue.—D. L.

JUDGING ROSES.

I ENTIRELY agree with "A. G. S., *Irnham*," in his remarks about points being given to a Tea Rose, and, as some of your readers may remember, I have several times urged this point in the Journal; but "D., *Deal*," has always opposed me, and as my devotion to the Teas is so well known I did not like to mention the matter in my article.

I am delighted to hear of the advent of another great grower, for the more the merrier and the better for trade.

A Tea should always have extra points, but how few judges give them! If I may mention names without offence I may say that two great trade-growers will always give them, and they are Mr. Benjamin R. Cant and Mr. John Keynes. Among amateurs I believe Mr. Peach and Mr. Jowitt would always give points, and I need say nothing of myself; but even Mr. Baker, and I believe Canon Hole and Mr. Pochin, will not do so. Here a rule would be of service—"Points are or are not to be given to Tea or Noisette Roses" as the National Society may determine. But I trust for the credit of that Society and of each individual member that the point will be settled in the affirmative.

Here is my case, and I will put it in a logical form:—The most lovely varieties have the most points given them; Tea and Noisette Roses are the most lovely, ∴ Tea Roses should have the most points.

My opponents will say, We deny your minor premiss, or you have to show that the Teas are the most lovely Roses. Is there any doubt on the matter? Is there any rosarian worthy of the name so blind and with such a chronic bad cold in the head that he cannot see that a Tea is infinitely the best of all Roses? Is it form you want? Tell me what form will equal or in any way approach *Souvenir d'un Ami*? Is it colour? Show me a H.P. Rose that can come within a mile of *Maréchal Niel* or *Cloth of Gold*. Is it fragrance? Why, there are none of the Hybrid Perpetuals which have the refined fragrance of *Catherine Mermet*! Compare the bouquet of *Steinberger* or *Marobrinzer* with *Rudesheim* or any of the coarser Rhine wines, and you will form some idea of the difference in fragrance between a bloom of *Catherine Mermet* and a *Charles Lefebvre* or my namesake. If I may make another simile from wine I would say that the latter is like the sweet, sugary, doctored stuff called champagne which is made from the generous Gooseberry, while the former is the Brutt wine of Gonlet or Giesler.

In size I own the Tea is generally deficient, but what of that? Size is the very last qualification, let the midland Rose-growers say what they will, and in all other points the Tea is infinitely the best. So that I maintain that my minor premiss is correct, and that the Teas and Noisettes ought to have the most points. But whether they will obtain them or not in the future is a matter that no fellow can say, least of all a—WYLD SAVAGE.

I DO not think there is in the end much difference of opinion between me and my friend "WYLD SAVAGE" with regard to judging Roses. When I said Give three points to the best Roses in a stand, then choose those only considered worthy of one point, the balance, unless some are bad enough to be cut out altogether, would come under the category of two points, and this is practically what is done when, as he says, three judges go together to judge the seventy-two singles, forty-eight

trebles, or whatever the class may be. Each judge in turn should choose those Roses he thinks worthy of the highest points, and if the other two judges agree there is no difficulty. In cases of doubt two judges' opinions will give the vote. If, when a Rose bloom is named by the judge as worthy of three points the other judges are doubtful, then a closer inspection into the merits of the individual Rose should be made by taking more closely the canons or rules for judging the merits of a bloom, and here I think the National Rose Society would do well to lay down some code of laws. "WYLD SAVAGE" and I are very near in accord with regard to those rules, but at present I want to show that if three judges are judging together, and first all the best Roses are selected out of each stand (likely to be, say, in the first four stands), and afterwards the inferior blooms, those that are left take the medium position; and it simplifies matters to count so many blooms at three points, so many at one, and the balance at two, and make as I said a mere sum in arithmetic.

In cases of doubt and difficulty where, as in some cases, stands Nos. 3 and 4 run close together, it will be necessary to compare the merits of individual Roses of the same kind in the respective stands. For instance, a *La France* in one stand with a *La France* in another, or an *Alfred Colomb*, *C. Lefebvre*, &c., in both stands; then, as I said in my notes in your issue of January 10th, a certain number of Roses will be worth an extra point. I do not think it a good plan to go from one stand to another merely counting the first-class Roses only in each stand; it is better to finish each stand as you go on, taking the number of the stand, then in the stand the number of first-class, second-class, and inferior blooms; and again I say, if three points are given to the first, two to the second, and one to the third, there will in the end the same decision be arrived at, and what "WYLD SAVAGE" calls the accidentals of the stands—that is, the evenness, or freshness, or variety of the different stands are virtually settled in the first onset, instead of having to go back. One thing, however, must always be borne in mind—judges are apt to become more critical as their eye becomes accustomed to very good blooms; in other words Roses are apt to obtain three points at first commencing the judging which might only have two points given afterwards, and it is as well to go back again to the first few stands to see if the judges have become more hypercritical or not. I have also known occasions when, owing to bad weather, heavy rains and wind, and the like, many really good blooms were damaged and discoloured which were evidently better than others which had come from more sheltered quarters, and where judges were obliged in the end to be lenient and not allow an inferior stand of Roses to win merely because the better Roses had suffered from rude Boreas. I do not, of course, mean cases where Roses were overblown, or too far gone, or too much damaged.

And now as to points of merit in individual Roses. Whether the judges actually count them or not, there is a certain standard of excellence which those who are accustomed to the work of judging lay down for themselves. It may be imperceptibly, but still all judges are to a certain extent guided by those points; and I think it will in the end be a great advantage if a code of laws, not such, perhaps, as those of the Medes and Persians, but such as would guide beginners, were laid down by the National Rose Society. "WYLD SAVAGE" and I both agree that form and symmetry, or what he calls shape, comes first. I have taken smoothness of petal, substance of petal, shape of petal next, because virtually the form and symmetry of the individual Rose depends on the petals. "WYLD SAVAGE" places colour, freshness, and substance before size. While quite agreeing with him that too much stress must not be laid upon size, yet the quality, quantity, and vigour, with freshness of the Rose, much depends as a rule on the size, though there are cases of overgrown monstrosities, coarseness of growth and so on, yet these would be at once cut out by the first canon—they would have neither form, shape, nor symmetry. So I am inclined to think on the whole that size is a more important element than either colour or freshness, which may be found in blooms otherwise small and inferior. "WYLD SAVAGE" himself, too, seems to lay a good deal of stress on size, if he allows only two or three blooms to each plant, and talks of a *Marquise de Mortemart* brought to perfection by cutting away all the plant but the single stem which had the flower. If size is to rank last, why disbud, thin-out, &c.? I do not mean, again, that dulness or want of freshness ought to be tolerated, but due allowance should be made for the distance that Roses have to travel and the difficulties that ex-

hibitors have to contend with, and really good Roses ought not to suffer merely because other growers are near at hand.

I am glad "D." agrees with me about Tea Roses, as so much depends where the Roses come from; and then so many Tea Roses are wired to pieces of stick to show their heads to the public, and this I, together with "A LOVER OF ROSE SHOWS," strongly object to. I do not want too much stress upon good blooms of Roses difficult to grow, but when men are judging who are acquainted with the habits of the different Roses these points naturally crop up. I quite agree with "D." as to symmetry in the stand. Large blooms of Paul Neyron and the like injudiciously placed often spoil the harmony of the whole. No doubt moss green and damp both sets off the stand and assists the Roses when coming a long journey, but I question if the moss and setting-up ought to go for much, if anything, in judging between two stands, unless the setting-up in one case was very inferior. I agree with the "SAVAGE," that Mr. Curtis's plan is perhaps ingenious, but it would not work, which is the main point we have to consider. My friend "D." of Deal is right no doubt to break a lance with me about Mr. Radclyffe; still I cannot accept his dictum about Roses against the results of the tabulated elections, not that these election lists will please all parties. "WYLD SAVAGE" did not like that of 1876. I much doubt if he prefers that of 1877. But whatever may be the individual opinions of rosarians the lists have been and are of great use, and would be more so if our nurserymen took more pains in testing the merits of novelties, and did not too often place their own novelties in the first rank; but then every mother thinks her own baby the finest, and due allowance must be made for hobbies.—C. P. PEACH.

THE able article in the last number of the Journal on judging Roses concludes with the following words—"I have written these notes in the hope that they will provoke discussion, and that they will afford a basis upon which Rose-growers may express their opinions. I am aware that there is a feeling abroad that some rules as to judging are to be desired, but I must say such an idea is not shared in by a Wyld Savage."

This paragraph has induced me to give my opinion on the subject. I agree with "D., Deal," that now we have a National Rose Society it certainly is desirable that a code of rules should be drawn up by a Committee of that Society, as a guide, I think, to exhibitors, such as small amateurs and novices in the art. There can be no doubt, if there had been rules prepared by the National last year and affixed to each schedule, there would not have been so many stands of such very indifferent Roses sent, neither would there have been one tithe of the inconvenience and consequently not so many disappointed exhibitors. By adding the rules to each schedule annually every recipient thereof would know, if he exhibited, what would be required of him in his stand to make him a successful competitor; and should he not succeed, his knowing the points on which he was beaten would stimulate him to obtain better things in the future.

I do not imply that rules are necessary for judges, for I contend that no man is qualified to adjudicate on a number of stands of Roses with any degree of fairness to the competitors unless—mark the word—unless he has been more than once a successful exhibitor himself. I mention this because I saw in a former number of the Journal a correspondent saying he was a frequent judge in close contests. Now I have no recollection of his ever having taken a prize for Roses, and for that reason I should look upon his judgment in the matter with suspicion.

Well may "WYLD SAVAGE" say that "H. C.'s" ideas of judging Roses "strike him with amazement," is "simply impracticable," and the "most bewildering one he ever heard of." I consider it to be a Quixotic idea. Picture to oneself judges who are "only required to know a bad from a good bloom." In all probability "H. C." himself would demur sometimes if left to the tender mercies of such experts.

With respect to Tea Roses having extra points reckoned in their favour is to my mind beyond the question. Should there be two or three very good blooms of Tea Roses in a stand by all means let them have every point they merit, but not more than would be given to equally good blooms of Hybrid Perpetuals, otherwise it would be quite as needful to award extra points to some of the more delicate-growing Hybrid Perpetuals over those in the same section of more vigorous and robust growth. Again, who would think of awarding the same number of points to a poor bloom of the Tea Rose section as to a good one of Hybrid Perpetuals? because it would stand thus: If

good Teas are to have extra points bad blooms would be on equal terms with good Hybrid Perpetuals.—J. RIDOUT.

POTATOES FROM SINGLE EYES.

So long as new varieties of Potatoes are sold at the same price per pound as market tubers are sold per peck, so long will those who purchase the novelties adopt the plan of cutting the sets into single eyes as a quick mode of increasing the stock. It is to America that we are indebted for many new and highly prized Potatoes, and America through Messrs. B. K. Bliss & Sons of New York has reduced the mode of cutting them to a system. For the following illustration of

Fig. 19.—How to Cut a Single Eye.

that system, and accompanying notes, we are indebted to Messrs. Hooper & Co.'s newly-published "Gardening Guide," a copiously illustrated book (not a trade catalogue) containing such clearly descriptive notes and sound cultural hints on flowers and vegetables as must be very welcome to amateurs.

"HOW TO CUT A POTATO TO A SINGLE EYE.—Take any Potato and hold it before you, with the stem end (the place where it was joined to the vine) down; it will then be noticed that the eyes are arranged around the tuber in regular ascending rotation from the bottom to the top, similar to the thread of a corkscrew, each eye being a little above and further around the side than the one next below it. Now take the Potato in the left hand with the stem end down, keeping it in a perpendicular position throughout the entire cutting. Take a sharp thin-bladed knife and remove the first eye by placing the knife about equally distant between it and the eye next in rotation above it, sloping it to the indenture left by the stem

(see dotted lines in centre cut), removing the flesh with it. When the first eye is removed turn the Potato around in the hand until the next eye above appears. Remove this one in the same manner, and keep on turning the Potato, removing each eye as it appears in exact rotation, always sloping the knife to the stem. After three or four eyes are thus removed the bottom part of the tuber will have a somewhat pyramidal form (see centre cut). It will be noticed that each eye removed has a similar form to that represented by the cut on the left, and has its proportionate share of the flesh attached.

"After the first two eyes are removed no further trouble will be found until the seed end is reached, and only a little extra care will be required to remove these closely clustered eyes. The cut on the right represents what remains of the Potato after all but the small eyes are removed, while the dotted lines show how to separate each of these. It will be noticed that the base retains the same form throughout, and by sloping the knife each time, and cutting down to the apex of this inverted pyramid (which is the centre of the tuber), each eye will be supported by an equal amount of the flesh, which is to start it into a strong healthy growth. With common varieties, where seed is cheap, many will think this manner of cutting too troublesome; but to those who wish to obtain a large increase from a small quantity of seed, as is necessary to those who buy the new varieties, this manner of cutting so that every eye is saved will prove invaluable."

ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 12TH.

THE annual general meeting of the Royal Horticultural Society was held in the Council-room, South Kensington, last Tuesday, the President, Lord Aberdare, in the chair. The members of the Council present were Lord Alfred S. Churchill, Major R. Trevor Clarke, Major Mason, Dr. Denny, Mr. W. B. Kellock, Mr. William Haughton, Mr. Henry Webb (Treasurer), and Dr. Hogg, (Secretary). Amongst the Fellows present were Mr. A. Grote, Mr. G. F. Wilson, Mr. Wills, Mr. Guedalla, Mr. Bateman, F.R.S., Sir Trevor Lawrence, &c.

Mr. S. JENNINGS, the Assistant Secretary, read the minutes of the last annual general meeting, which, upon the proposition of the President, were confirmed.

THE PRESIDENT said the next business before the meeting was the nomination of the Expenses Committee and of the Auditors. The names were in the list which was in the hands of the Fellows. The Expenses Committee proposed were Mr. F. Campion, Mr. Henry Webb, and Mr. William Haughton; but, unfortunately, Mr. Campion had sent in his resignation, and was therefore disqualified from filling the office, and the Council asked that the name of Lord Alfred S. Churchill should be substituted. One of the Auditors, Mr. Charles Edmonds, had removed into the country, and was consequently unable to perform the duties of an auditor, and hence the Council proposed the name of Mr. R. A. Aspinall, who had kindly consented to undertake the duties of an auditor. "This was agreed to.

THE PRESIDENT said the next business was to appoint scrutineers for the ballot, and he had to submit the names of Messrs. Lee and Bull. This was also agreed to.

THE PRESIDENT.—The next duty I have to discharge is to propose that the report of the Council should be read; but probably it will be on this occasion, as it usually is, the desire of the meeting that the report be taken as read, inasmuch as it has been for some days in the hands of Fellows [hear, hear]. That being so, I hope the Fellows will agree with me and my colleagues that the report is an encouraging and cheering one [hear, hear]; that it exhibits signs, not of disappointed hopes almost brought to the verge of despair, which was the case in some of the preceding reports of the Council of this Society, but that it is one full of animation and of the promise of a healthy life [hear, hear]. We met last year under many advantages, but still many discouragements. These were the falling-off of a considerable number of the Fellows, caused to a very large extent by the great disunion which existed up to that time in the Society. The number of Fellows up to the last two years had been steadily decreasing, and that decrease went on at an accelerating ratio; and the result is, that although during the last year we may be considered to have very much recovered ourselves, the whole number of Fellows is less at this moment than it was at the commencement of 1876. Still, the accession of numbers last year has been very considerable [hear, hear]; and great a sign as this is, we have also other signs that there is a returning confidence of the public towards this Society. The report shows you that while during the past year seventy-nine Fellows resigned and sixty Fellows died, we have had an accession of no less than 256 new Fellows and 281 guinea members, so that you see, in point of fact, the increase of numbers was very great [hear, hear]. That is really a fact which ought to be steadily borne in mind when the prospects of the

Society are taken into consideration. But this is only one symptom of reviving confidence in the Society. Another cause of encouragement is, that the disputes which unfortunately hitherto existed in our meetings, and which undoubtedly produced a very bad effect in the minds of the public, have entirely disappeared. That, too, I consider is a gratifying announcement to be able to make [hear, hear]. The Society determined to avail themselves of this new feeling of confidence by great exertions on their part; and these exertions, I am happy to say, have been successful. It will be agreed, I am sure, on all hands that the fortnightly shows which the Society has held were not only equal but much superior to those of former years, whether as regarded their value in a scientific point of view, in one of horticultural interest, or their external beauty [cheers]. In no year have we had any more magnificent shows [hear, hear]. Then, again, beyond that we have the very best practical proof, in the shape of our very large receipts, of the increased prosperity of our shows and of their increased popularity, when we were able for the first time to invite Her Majesty to these gardens, and also the Prince and the Princess of Wales. I say for the "first time," because I, as President of the Society, steadily refused to invite Her Majesty here until the unhappy dissensions in the Society had disappeared—until there was some sort of general concord amongst its members and a reasonable hope that harmony was established [hear]. We have had the advantage of the presence of the Queen accompanied by some of the Princesses, and afterwards of the presence of the Prince and Princess of Wales, as well of the Duke of Teck, the President of, not the rival, but the sister Society—the Botanical Society, accompanied by the Duchess. The result of all this is, that while in 1875 we received from our exhibitions only £222, and in 1876 only £223, we actually received in 1877 from our exhibitions £812 [cheers]. The daily admissions rose last year to £484, while in the preceding year they only amounted to £245. Then as regards our garden produce, while we sold it to the amount of £340 in 1876, last year it realised £577. All these things show a very great advance on the part of the Society, an improved condition of things in most important points [hear, hear]. There is one other little matter which I think I should bring under your notice before I sit down, and that is the disappearance from the accounts of the £1700 which was placed to the credit of our provincial shows. The provincial shows of the Society had been highly successful, and the existing Council of the day—as they had a perfect right to do—placed the balance of receipts or surplus arising from those shows to a separate account, which was to form a guarantee fund for provincial shows in the future, as they were found to be of great advantage to the Society. But, in other times, another Council which was appointed found themselves in embarrassments and difficulties, and they appropriated this sum of £1700, so specially set aside for a special purpose, to supply the general necessities of the Society. I have no doubt they had a legal right to do so. It may have been unfortunate that they did so, but I think they had as much right to get the money for the general wants of the Society as the previous Council had to say the £1700 was to be specially devoted to provincial shows. The Council thought and felt they had an equal right to say, "It was all very well to set it aside, but now we will apply it to the general wants of the Society." At any rate, whether my view is right or not, and I am bound to say it was confirmed by the opinion of an eminent counsel, the omission of that item from our balance sheet was actually forced upon us by the auditors, who refused to sign our accounts so long as that item of £1700 appeared in them as a fictitious one. We have, as to our future provincial shows, entered into a contract with those who will assist us that, with respect to any surplus to be set aside, neither the Council nor any other body shall have power to lay their hands upon it for any other purpose than that intended by the trustees [hear, hear]. I assure you, therefore, that during the last year we have shown very considerable symptoms of reviving prosperity. We have had a large increase in the number of Fellows, and I have every ground for hoping that the returning flood of prosperity will continue during the present year [cheers]. The only way we can increase our revenue, having tried every other means, is by showing the public we are exerting ourselves to do our best, by showing horticulturists we are doing our utmost to advance the interests of horticultural science, and by showing those who live in this neighbourhood that the Council are making the attractions of these gardens as great as possible [hear, hear]. I mention this because a gentleman—and I am not aware whether he is present in the room or not—has written to me to say he should move for the appointment of a committee of Fellows, who should institute an inquiry to see what can be done to promote the interests of the Society. Well, I think we had quite enough of these committees of inquiry [hear, hear]. I know very well that in many cases of contingency and emergency there is a very great advantage in the appointment of such a committee of inquiry, but at the present time the appointment of such a committee would only show the existence of differences which do not exist [hear, hear and cheers]. I may say without presumption the Council does possess the confidence of the Fellows, and we

are all convinced that anything like a suggestion of disunion must, at the present stage of our history, be of a very injurious character [cheers]. A friend of mine who always says wise things and often witty ones, speaking a short time since of the visit of the Queen to the show, and then talking of the services of my friend on my right (Dr. Hogg) in the science of pomology, remarked that besides promoting the cultivation of Apples the Council had been successful in expelling the apple of discord [cheers and laughter]. I hope it has been thoroughly extirpated, and therefore I am very anxious that nothing should be done to show the appearance of want of harmony in the Council [hear, hear]. We are giving the strongest outward visible signs to the public of our existence and of our capacity for usefulness. Last year, from all the information I have received, our shows were not—could not be—surpassed in usefulness and brilliancy; but I believe even they will be surpassed by the shows of this year. We have made arrangements for an exhibition in May extending over four days; and we have made preparations for holding a show at Preston which will also last four days, and I hope it will be an accession not only of revenue but of credit [hear, hear]. The only cloud hanging over our fortunes is the existence of the arrangement entered into with Her Majesty's Commissioners as to the termination of our agreement with them in case that at the end of December this year we should not have an income of £10,000. Well, our income last year amounted to about £5780, which is a long way from £10,000; but considering the great depression which had existed in the country as well as the general desire of people to diminish their expenditure and not to increase it, that was not a year in which we should expect to do what we pledged ourselves to do our best to accomplish. At the same time I know Her Majesty's Commissioners are watching our proceedings with an attentive eye. I know they are aware we are doing our best to attain the object for which we were incorporated, and that all of them will have the justice to see the difficulty under these adverse circumstances of bringing together within the limit of time stipulated such an income as that of £10,000. Under these circumstances I am strongly inclined to hope—I speak my own opinion—that Her Majesty's Commissioners will extend the period so as to give us the advantages of the improvements we may not unreasonably look for in those better times when people will be more inclined to become Fellows of the Society than they were during 1877 [hear, hear]. Taking all the circumstances together we may consider that the report which I ask you to adopt presents a hopeful view of our situation, and therefore it is with confidence that I beg to move it be adopted.

Lord ALFRED S. CHURCHILL seconded the motion.

Mr. GURDALLA took the same view of the situation as their noble President did. Under his able presidency they were slowly mending for the better, and he felt sure that if some arrangement with the Commissioners could be made the Society would be able in the course of a few years to increase their income to £10,000. When he looked at the great mansions in that neighbourhood he could not but think of the serious injury which would accrue if the gardens were built upon, and it was to his perfect astonishment that all round about in the neighbourhood did not endeavour to keep up the gardens [hear, hear]. No doubt horticultural science could be carried on elsewhere than in South Kensington, but was not the latter the place in which the late illustrious Prince Consort, whom they all lamented, initiated the gardens? [hear, hear]. He should be very pleased if the Commissioners would come down to £7000 income for next year, and that if the income of the Society were so increased the Commissioners would not adopt the strict letter of law. He did not wish to say this in the way of a menace or threat, but the Commissioners must know the Society was not going to surrender without an effort. The Society had done a good deal; there were the debenture holders and other interests to be looked to, and he should be very glad in this matter to take the word of their noble Chairman that the Council would do their best. With extraordinary aids a forced income might be got together. Above all things he thought it desirable that the Commissioners and the Council should work in harmony together. With these observations he supported the motion for the adoption of the report [hear, hear].

Mr. GEORGE F. WILSON was sorry to hear the £1700 was put out of chance of recovery. He spoke feelingly, as he was on the Council when the first provincial show took place. When it was proposed to hold the show the Commissioners of the Exhibition of 1861 said they could not sanction the expenditure, as it was not for the purposes of the South Kensington estate; but the Council took the responsibility on themselves. He thought it was very hard, that being the case, that the money should go for the general purposes of the Society. It was distinctly said that any money earned by that show should be devoted to horticultural and not to general purposes [hear, hear]. He wished to say he should have liked all the guinea members should have votes, and he had reason to know if that were the case there would be a great accession of members. However, it was distinctly said when the guinea members were accepted they should have all the privileges of membership except the vote, and yet he was sorry to find that when the great show was held in June—and one-

guinea members took the greatest interest in the shows—an announcement was made by the Council to the effect that the Fellows and debenture holders were to be admitted at twelve o'clock, while the guinea members and the public were to be admitted at one o'clock. Now it was, he repeated, distinctly said that the guinea members were to have every privilege with the exception of that of voting. He hoped that would be put right this year [hear, hear]. As to the last paragraph in the report in which the Council "earnestly urge upon the Fellows the imperative necessity of using every effort to increase their numbers so as to comply with the condition imposed by the last agreement with Her Majesty's Commissioners, and secure their tenure of the South Kensington Gardens and the emancipation of the Society from its difficulties," he, for one, hoped that would be the only tenure by which the gardens would be held.

The PRESIDENT said he strongly agreed with Mr. Wilson that no distinction as to the admission of guinea members should be made. He now put the motion "That the report be adopted."

The motion was carried unanimously.

The following officers were unanimously elected:—President, Right Hon. Lord Aberdare; Treasurer, Henry Webb; Secretary, Robert Hogg; Expenses Committeemen, Lord A. Churchill, Henry Webb, and William Haughton; Auditors, R. A. Aspinall, John Lee, and James F. West. The names of vacating members of Council were F. Campion, W. B. Kellock, F.L.S., and T. M. Shuttleworth. The following were elected to fill the above-mentioned ordinary vacancies:—C. J. Freake; Sir Trevor Lawrence, Bart., M.P.; and J. T. D. Llewellyn.

Mr. WILLS asked whether any preparations for the Show at Preston were going on, and if so if they were progressing satisfactorily.

The PRESIDENT replied that a local committee of influential gentlemen had been appointed, and they were acting with the Council. There was every reason to expect that the Show would be a good one, and up to the present moment all the preparations were going on satisfactorily [hear, hear].

The meeting then separated.

REPORT OF THE COUNCIL TO THE ANNUAL GENERAL MEETING OF 12TH FEBRUARY, 1878.

The operations of the Society have, during the past year, been carried on with a completeness and efficiency which the Council did not venture to hope for at the time of the last annual meeting. The Scientific, Fruit, and Floral Committees were most assiduous in the performance of the duties which they have undertaken respectively, and the results of their valuable labours, and of many of the practical trials and experiments made at Chiswick, the Council hoped would have been made public in the *Journal* of the Society, which they attempted to recommence. Unfortunately the illness, which terminated in the lamented death of Mr. Andrew Murray, whom they appointed to be its editor, prevented this expectation being realised. They have recently obtained the services of Mr. Samuel Jennings in the double capacity of Assistant Secretary and Editor of the *Journal*, which they trust will shortly re-appear in a form worthy of the Society.

The plants, flowers, and fruit shown at the ordinary meetings of the Society always present objects of great interest from their rarity or unusual excellence in point of cultivation, but the limited space available for their exhibition in the Council chamber necessarily restricted their numbers and interfered with their effective display. To remedy this inconvenience to some extent, and to enable Fellows to enjoy with more comfort to themselves the beauty of these exhibitions, the Council held them in the conservatory during the past season. The experiment proved successful beyond expectation; the cordial co-operation of the chief exhibitors rendered these unpretending meetings worthy of being classed as regular shows. The Council have the gratification of knowing that they afforded much pleasure to the Fellows, and they will resume them in March next. Fellows' tickets and small book orders will admit as on ordinary days. Cards giving full information as to the dates of the shows and meetings for this year will be ready for distribution as soon after the annual meeting as they can be printed.

The magnificent shows which were honoured by the presence of Her Majesty and the Prince and Princess of Wales, and the show of Covent Garden produce, in which the Duke and Duchess of Teck showed a lively interest, were in every respect worthy of the Society. The Council hope that the two former will be quite equalled, if not exceeded, in extent and beauty by the four-days show which will be held in May next.

The Council have during the last two years wished to organise a provincial show on a grand scale; but the practical extinction of the fund formerly set apart for this purpose by the appropriation of £1700 to other uses (which they have been advised cannot be recovered, and which, therefore, does not appear in the balance sheet), and the failure of their attempts to obtain sufficient local support, have hitherto prevented the accomplishment of their wish. Now, however, a guarantee fund has been raised and arrangements made at Preston which justify the show which has been announced being held there. The form of guarantee

provides for the future security from misappropriation of the profits specified in it, and the Secretary will be happy to receive the names of those willing to become guarantors.

the names of those willing to become guarantors.

At Chiswick many valuable experiments have been made, the results of which will shortly be published in the Society's Journal. The state of the garden is most satisfactory. The great vinery, probably the finest of its kind in the world, the Vines in which are twenty years old, produced an abundant crop, which, at the reduced prices at which the Grapes were sold to Fellows, realised £820. The Vines planted against the glazed wall for identification and description have been removed, and their places will be filled by others bearing fruit of greater value. The Vines removed are retained in the garden for distribution to Fellows. Full descriptions of them have been drawn up and will be published. The Peach trees trained as single "cordons" are well worthy of inspection; their crop was good and of high quality. Trials have been made of 77 varieties of Tomatoes (some grown in pots, some in the open ground); of 153 samples of Turnips, sown at different seasons; of 67 samples of Savoy's, and 188 samples of Cabbages, of all of which except the last reports are ready. The last, which have been tested as to their value for summer and autumn use, have been again planted to ascertain their value for use in spring. Of most of the typical kinds photographs have been taken. In the present year collections of Peas, Lettuces, Beets, and Leeks will be subjected to critical examination, and experiments will be made on the comparative value of artificial manures. The collection of herbaceous plants has been rearranged and largely added to. The Council have also procured collections of some of the more ornamental kinds of these plants and florists' flowers, including Delphiniums, Pæonias, Pyrethrums, Iris, Ranunculus, Crocus, &c., which have been separately planted. A rockery, for the stone of which the Council are indebted to their Treasurer, Mr. Henry Webb, has been formed opposite the entrance to the great vinery, and planted with rock plants, many of which of great interest were presented by the Royal Gardens, Kew: the Royal Botanic Garden, Edinburgh; Mr. G. F. Wilson, Mr. George Maw, and others. Trials have been made of various kinds of Zonal Pelargoniums (which were successfully grown, both in pots and planted out in the open border), also of varieties of Canna, Begonia, Epacris, China Asters, Stocks, and various sorts of hardy annuals, of all of which full reports have been prepared.

The liberality of Mr. Elwes, a member of Council, who has procured the seeds of many plants from the Sikkim Himalayas, will enable the Council to distribute some of these, which are of great beauty and rarity, among the Fellows in the course of this year.

The Council are desirous of opening up correspondence with persons residing in the Colonies and abroad who would send home seeds and plants, and they hope that all who can facilitate their efforts in the introduction of new plants will communicate with the Assistant Secretary to that effect.

520 packets of cuttings of fruit trees, 1695 plants, 195 packets of cuttings of plants, and 15,850 packets of seeds have been distributed among Fellows during the past year.

The mode of heating the glass houses has been altered, and an economy in the consumption of fuel thereby effected.

A new carriage entrance to the garden has been opened.

At South Kensington repairs to a considerable extent have been carried out, but much remains to be done in this respect.

The Saturday promenades recommenced on the 19th January last.

The ordinary receipts for the year have exceeded the expenditure by £11 17s. 2d., to which must be added the sum of £836 19s. 7d., levied upon and paid by the Society in past years in respect of rates, which should have been paid by Her Majesty's Commissioners, and which they have repaid to the Society.

The Council hope to be able to continue and extend the operation of the arrangement with the debenture holders referred to in their recent circular.

During the past year 255 new Fellows and 281 guinea Members were elected ; 79 Fellows resigned, and 60 Fellows died.

In conclusion the Council earnestly urge upon the Fellows the imperative necessity of using every effort to increase their numbers, so as to comply with the condition imposed by the last agreement with Her Majesty's Commissioners, and secure their tenure of the South Kennington Gardens and the emancipation of the Society from its difficulties.

February 5th, 1878.

NOTES FROM MY GARDEN IN 1877.

It is always more pleasant to look back on successes than failures, even though failures by exposing defects may lead to greater efficiency hereafter ; but I suppose there are few owners of a garden that do not speak disparagingly of the last year. From all parts of the country the same tale has been told—a mild winter succeeded by a cold spring, an indifferent summer and cheerless autumn ; and in whatever part of the garden an amateur took pleasure his pleasure was considerably damped (I mean no pun) by the failures he experienced. Everything in the latter part of the winter promised an unusually early season, but all were in truth very late—at least three weeks beyond their time : the only exception that I found to this, strangely enough, were Christmas Roses (*Helleborus niger*), which were at least three weeks before their proper season for blooming. And this leads me to say that herbaceous and

alpine plants, being so much more independent of season than many things, afford a very real and well-nigh certain pleasure; and even in my small garden there was rarely any week in the year when that pleasure was not experienced. From the time that (long before the Snowdrops) the early and most sturdy little Cyclamens that seem to defy all weathers threw up their bright and pretty blossoms until the late-flowering Asters closed the autumn there was always something to be looked at.

One of these early gems which I have been for years trying to succeed with, and which many a more practised hand has had to confess he has failed to grow properly, is the lovely *Gentiana verna*. I am hopeful that I have at last found out how to do it, as my plants not only bloomed last year but are promising to bloom again this spring. My plan has been to take out the soil in a small portion of the rockery and fill it in with peat into which small pieces of stone were placed; the Gentians were then planted, and one or two plants of the very minute *Arenaria balearica* planted amongst them. This very rapidly covered the space, ran in amongst and indeed covered the Gentians. These, however, soon asserted their presence and pushed up through the *Arenaria*, and are so doing again. In fact it is an imitation of the way in which they are found in Alpine regions—never growing on the bare ground, but developing their beauties amidst the short and dense pasture along with *Silene acaulis*.

Another plant that has done well with me is the beautiful North American *Cypripedium spectabile*. This was planted in a moist spot of the rockery somewhat in shade, in peat, and last year the flowering stem had two blooms upon it, which is not usual, and portends vigour I imagine. I have added two more plants this season, and hope they may succeed equally well. During the summer months when the weather was at all dry it was frequently watered—sometimes twice a-day, as it is so very fond of moisture. The finest clumps of it that I have seen in the open ground were with my friend Dr. Stiles of Spalding, who had them in a shady corner in his walled-in garden, where they were luxuriating freely; and of those grown in pots I have never seen any equal to those which my friend Mr. Broome exhibited at Manchester. As a hardy perennial it has few equals, and should be cultivated wherever there is a spare nook for such beauties.

Amongst the novelties that I had this season was *Senecio pulcher*, and one, although to some persons' taste somewhat coarse, is nevertheless a very showy and handsome flower. The colour is purplish crimson; the habit of the plant is vigorous, the thick fleshy stems rising from the centre and bearing several flowers which are from 3 to 4 inches in diameter. Being an autumnal bloomer it will be a valuable addition to the herbaceous border.

One of the most persistent bloomers in the garden during the summer and autumn months has been the very showy *Aquilegia chrysantha*. There was hardly any time when I could not go and gather a few of its blooms for arranging in small vases.

Is there any way of growing properly the curious little *Sedum arachnoideum* out of doors? I have seen it in fissures in the rocks near the Mer de Glace in Switzerland where there could hardly have been a particle of earth, and during the hot weather it must have been roasted, and yet it was in great beauty. With me it loses that striking peculiarity, the thread-like web that overspreads it. I have seen it in great beauty in Messrs. Lucombe & Pince's nursery at Exeter and in some other places, but have failed hitherto to grow it as I wish, although I have endeavoured to imitate its habitat as I saw it by placing it in fissures in the rockery.

I have had several new *Delphiniums* in the border, but there are few of them that I prefer to some of the older varieties, such as *Belladonna* and *Madame Henri Jacotot*. The beautiful blue of the former is unequalled by any other variety. One of the most useful plants I have found for cutting is the little *Hop Marjoram* (*Origanum*), so often seen in cottage windows, but perfectly hardy and very fragrant. It adds quite a character to the vases in which it is placed, and tends to take off the stiffness that too often is noticeable in them.

Another somewhat neglected plant, but very useful for the same purpose, is the old *Gladiolus Colvilli alba*, while of course no garden can be without *Anemone japonica* *Honorine Jobert*, which with me is quite a weed and has to be treated accordingly.

These few rambling notes are something like my garden itself, where no method prevails, fruit, vegetables, and flowers being mixed up together; but I have thus run on because

whatever may have been my trials as a florist last year, and they were neither few nor slight, I was ever finding some fresh beauty in the limited number of herbaceous plants to console me when *Auriculas*, *Gladioli*, and *Carnations* only caused heavy sighs and groans.—D., *Deal*.

CEPHALOTUS FOLLICULARIS.

THIS little gem, well known as the Australian Pitcher Plant, has its leaves formed into pitchers, covered with a lid, in a manner similar to those of the famous *Nepenthes*. It was first discovered and described by the French botanist Labillardière, in Lewins Land, more than fifty years ago, and has since been found in many other of the Australian marshes. To lovers of curious plants there are few more attractive than *Cephalotus*; and from its tiny size there are few collections in which it might not have a place. It is somewhat remarkable, however, that it is now comparatively seldom met with, and seems indeed in danger of disappearing from our list of cultivated plants. This we believe is caused, to some extent at least, by a mistaken idea that it is difficult to manage. Having paid considerable attention to its requirements, and been successful in its cultivation, we venture to give a few hints which may be profitable to beginners.

The best time for shifting is in spring immediately before growth commences, using a compost of rotted sphagnum moss, fibry peat, small potsherds, and sharp sand in equal proportions. In potting the old soil should be removed from the roots so far as can be done without damaging them, and the plant raised slightly above the level of the rim of the pot; and as water should be given liberally, particularly during the growing season, provision should be made for thorough drainage by a plentiful allowance of crocks. After potting the plant should be placed in moderate bottom heat in a situation where it can have all the light possible without being exposed to the direct rays of the sun. A moist atmosphere is indispensable to its well-being; and when it is grown in a mixed collection of plants it will be necessary to cover it with a bellglass, either with a hole at the top or slightly tilted at the edge, to allow the vapour to escape, and to admit a constant supply of fresh air. The roots should never be allowed to get dry; and it will be found a good plan to place the pots within others of a larger size, the vacant space being filled up with moss or rough peat. A temperature of from 50° to 60° while in active growth is all that is either necessary or even desirable—many of the failures in its management being due to too much heat, which induces quick but sickly growth, whereby the constitution of the plant is so weakened that it will almost certainly die off as winter approaches. A period of rest is also necessary, and in winter the plants should have a lower temperature, say from 40° to 50°, and only be watered when necessary, to prevent the roots from becoming completely dry. Green fly is a great enemy to this plant, and a constant vigilance should be exercised, so that it may be checked immediately on its appearance.

The best mode of propagating it is by division of the tufts, which is most successfully done when the plants are shifted in spring, the young plants being put into small pots individually or grouped together into large ones for the first season.—HUGH FRASER (in *The Gardener*).

PRIMULA AMGENA.—A successful cultivator of this attractive plant informs us that he has just been potting the plants of this *Primula* from the open ground, and has never seen finer crowns. After the plants ceased flowering last spring a portion of them were planted out in tolerably rich and light soil in a shaded situation, the remainder being kept in pots. Those that were planted out are, he states, far more robust and promising than those which have remained in pots throughout the season, and he intends adopting the planting-out system with all his plants, treating them the same as *Spirea japonica*.

KEEPING GRAPES.

BEFORE briefly referring to the effects of the condensation of moisture on the berries as accelerating their decay, I wish to say that I did not intend to attribute egotism or anything of the kind to Mr. D. Thomson. I simply accepted his own admission that it is some occult operation of Nature and not the skill of the cultivator that mainly contributes to the remarkable preservation of the Grapes at *Drumlanrig*. I

endeavoured to point out the manner in which Nature gave her valuable aid, and in the absence of sufficient evidence to the contrary advanced by Mr. Thomson I should still think I was right. I grant that that good cultivator has emphatically asserted that the district in which he resides is remarkable for hot days and clear nights, but I also remember that he has with at least equal emphasis asserted the great prevalence of cloud in Dumfriesshire. Under these circumstances I will do what is usual in such cases—take the mean. If “the condensation of moisture under glass on every leaf, twig, and bud is most remarkable,” how is it that he can grow Duke of Buccleuch Grape, as I have seen it there, without spot or blemish? A grower, who appears to have been singularly successful with that Grape, has stated on page 81 that it will not set nor finish well with much atmospheric moisture.

I will now pass on to “R. M. R.,” who has taken the starch out of my collar. If it is the rule for some Grapes to keep well and others of the same variety to decay rapidly when “bottled” and placed side by side in the regular temperature of a room, it is evident that some other cause than the deposition of moisture on them exerts an important influence on their keeping or non-keeping properties. I am quite content for this to be so, but have a great longing to know what that cause is and how its influence acts? I need not repeat my experience, but only ask that it be kept in mind as a small (I care not how small) element in connection with future observation on an important matter which it is clear is but imperfectly understood. I may remark that I am tolerably well acquainted with Mr. Thomson's mode of Vine culture, and I have great respect for my friend, whom it is not long since I visited. I hope it will not be long before I visit him again; but I do not promise then to tell him that I am—A NORTHERN GARDENER.

AN ELECTION OF PLANTS FOR TABLE DECORATION.

WITH a view of placing before the public the very best fine-foliage plants for table decoration, the Royal Horticultural, the Crystal Palace, and other horticultural societies both in London and in the provinces have from time to time offered prizes for a limited selection of plants suitable for the purpose named, to be grown in 6-inch pots.

The Wimbledon Horticultural Society has followed this example now for several years, and a very spirited contest has annually been the result. This being the case, it is not to be wondered that the subject of table plants came up for discussion at one of the meetings held in the gardens of Sir H. W. Peek, Bart., M.P. This led to an election of plants. The members of the Society, who are practical gardeners, voted the following twenty plants as the most suitable foliage plants for table decoration, and they are here named in the order of merit as determined by the returns of the electors.

1. *Cocos Weddelliana*.—This has the premier place, and is undoubtedly the most elegant small Palm in cultivation, and its high appreciation for table decoration was acknowledged by everyone present. When from 15 to 30 inches in height it is very beautiful; the stems are slender, and leaves long and gracefully arched.

2. *Aralia elegantissima*.—This was also considered to be one of the best of table plants. Its stem is straight, and is furnished at short intervals with slender palmate leaves supported on long footstalks; the leaflets are deeply serrated and gracefully pendulous; it is also very free in growth.

3. *Pandanus Veitchii*.—In a small state this plant is very graceful, and is much appreciated as a table plant. It is of a light green colour and beautifully striped with broad lines of pure white, the points of each leaf gracefully curving towards the pot. It is easily propagated by suckers, and the smaller and better coloured the suckers are when taken off, the more graceful and pendulous in habit become the plants.

4. *Croton angustifolium*.—Although one of the oldest of Crotons it has not yet been surpassed for table purposes by any of the many recent introductions. The long pendulous habit of its narrow yellow leaves is most effective. Cuttings are easily struck in a strong bottom heat, carefully retaining all the foliage possible. When struck the plants should occupy a light situation to bring out their bright yellow variegation.

5. *Dracena terminalis*.—Notwithstanding the marvellous increase of new varieties of *Dracena*, this, the oldest and best-known, is able to hold its own against all rivals, and there is more of this species cultivated annually for Covent Garden Market than of any other. The leaves are of a dark green

colour, richly shaded with brilliant scarlet; the upper part of the plant is sometimes wholly scarlet.

6. *Dracena gracilis*.—This is an elegant little plant with narrow bright shining green leaves gracefully curved, and so pleasing in habit that it ought to be grown even in the most limited collections.

7. *Cyperus alternifolius variegatus*.—This plant is so well known and so popular as not to need further description.

8. *Geonoma gracilis*.—This very beautiful dwarf-growing Palm is in no way inferior to the more popular *Cocos Weddelliana*. It is very graceful, and the whole appearance of the plant is very light, and has a pleasing softness in its green and finely divided leaves, which renders it a most useful plant for decorative purposes.

9. *Croton Johannis*.—This valuable *Croton* has the same graceful habit as *C. angustifolium*, the leaves attaining a length of 20 to 24 inches, and are beautifully marked with a bright orange yellow.

10. *Dæmonorops plumosa*.—This elegant dwarf Palm has fronds of a rich bright green colour and handsomely plumed. It is both distinct and graceful, and is admirably suited for table embellishment.

11. *Dracena Cooperi*.—This somewhat resembles the well-known *D. terminalis*, but is more pendulous in habit, and its leaves are more constant in their bright red colour.

12. *Adiantum cuneatum*.—This plant is so useful that it is grown in larger quantities than any other Fern. The electors had in view merit rather than novelty, hence this old favourite won a honourable position in the election.

13. *Pandanus elegantissimus*.—This when in a small state is an admirable plant for the table. It has dark green leaves, glaucous at the base, and is armed with red spines. It is somewhat upright in growth, yet is very elegant.

14. *Aralia leptophylla*.—This *Aralia* possesses a free growth combined with gracefulness of habit, which renders it a great favourite with many gardeners for the purpose in question.

15. *Croton majesticum*.—The regularly drooping, narrow, elongate leaves give this plant a very elegant character. It is very free-growing, and when well coloured it is peculiarly attractive by artificial light.

16. *Ananassa sativa variegata*, or Variegated Pine Apple, was considered by several members to be worthy of a higher place in the twenty. It is light and elegant, and has the advantage of keeping in a room a long time without injury.

17. *Reedia glaucescens*.—This highly distinct evergreen stove plant is remarkable for producing its miniature flowers at the margins of its Acacia-like leaflets. The flowers close at night and the leaves recurve, and the plant is therefore only suitable for daylight dinners. It is singularly chaste and attractive.

18. *Cyperus laevis*.—This is a decided acquisition to our table-decorative plants, having beautiful whorls of bright green leaves with feathery grass-like tufts of flowers in the centre. It is dwarf in habit and effective.

19. *Caladium argyrites*.—This *Caladium* is, when well grown, beautifully coloured, and is suitable for the table either as a dwarf plant employed singly, or for grouping in conjunction with other plants.

20. *Adiantum scutum*.—This plant, which completes the list, is one of the most graceful of the Maidenhairs, and is valuable for many decorative purposes.

The above plants were chosen more from their usefulness for the purpose suggested than from their rareness or scarcity. —J. W. MOORMAN.

DUKE OF BUCCLEUCH GRAPE.

I THINK the thanks of the readers of this Journal are due to Mr. Douglas for his reply to the remarks of your correspondent “COLUMBUS” concerning this Grape. “COLUMBUS” may have succeeded in pleasing his employer by growing it under favourable circumstances, for no doubt a good bunch of this variety is very fascinating, and as it is new would induce one to grow it largely. I have read a good deal about this Grape since its introduction, and most of your readers will agree with me that the opinions expressed were very conflicting, the majority being against “The Duke.” I have tried to grow it myself grafted on the Black Hamburgh, and I find it to have the following bad habits:—It is a bad setter, a shy bearer, a small buncher, a bad keeper, and an irregular breaker. Last autumn I saw some not bad bunches of it at Drumlanrig Gardens, and also at Carlisle International; but taking it as a whole it was the most miserable class in the Exhibition.

Not long ago I was talking to a nurseryman about Vines, and he told me that he had heard that the raiser of "The Duke" had pitched all his surplus plants to the rubbish heap in disgust. Can this be true?—B. G., Co. Down.

CORDICEPS ROBERTSII.

WE some time ago received from one of our correspondents a letter informing us of the receipt from New Zealand of a

Fig. 20.

1 and 2.—*Cordiceps Robertsii*, parasitic on caterpillar of *Hepialus virescens*.
3.—*Cordiceps Sinclairii*, the other New Zealand species, parasitic on the larva of an orthopterous insect.

"vegetable caterpillar," *Sphaeria Robertsii* by name, with a description taken from some encyclopædia as follows—"This creature, about the size of the little finger, feeds upon the leaves of the Rata. . . . At a particular stage of its growth the caterpillar drops from the tree, burrows a few inches into the earth, and there appears to change its nature and become a vegetable. for from the nape of its neck up sprouts a shoot of 6 or 8 inches long, rising above the surface something like a

rat's tail. The body of this insect, still quite perfect, assumes, shoots and all, a sort of ligneous character, and seems if kept dry to be reasonably indestructible." This description is the result of some misconception, and fails to indicate the exact nature of its subject, which is one of considerable interest. We lay before our readers the following brief account. The "shoot of 6 or 8 inches long" is really a fungus and called *Cordiceps Robertsii*, this and several other genera having been separated from *Sphaeria*. It is not uncommon in New Zealand. The caterpillar on which it invariably grows is that of *Hepialus virescens*, known as "Hotete" by the natives. It is doubtless attacked in a living state, which we should not have said had it not been in one case otherwise stated. Every now and then we meet with work of past time, in which it would seem that from insufficient knowledge or information people were afraid to follow where Nature directed. We mean that in this case it perhaps seemed rash to say that the caterpillar would be attacked when alive; and, to give further instance, we have just seen a drawing in which the artist was afraid apparently to copy Nature as he saw it, thinking it ought to be otherwise. The time of attack is when the caterpillar buries itself in the ground to undergo metamorphosis. It takes an upright position and is a little underground, so that the lower part of the fungus is also below the surface. It is supposed that in the act of working the soil the spores are lodged in the joint of the neck. In one account—the most trustworthy we know of—it is said to be found usually under tree Ferns, and in another we are informed that it feeds on the Sweet Potato (*Batatas edulis*).

The plants known by the Maori name of "Rata" are *Metrosideros robusta* and *M. florida*, but we are unable to find that it is a feeder on these plants; and indeed it is not likely if, as we are informed by an entomological friend, that the *Hepialidae* always feed on roots. We have not been able to discover that more than the one caterpillar is ever taken possession of by this plant. In all cases the fungus springs from the back of the neck of its victim just behind the head, the reason of which we have already given. It grows erect, and so the upright position of the caterpillar accounts for the preserved specimens being, the one with the other, always in a line. It is slightly flexuous, and when dry is more or less corky in texture, and the height varies from 2 to 8 inches. When not shrunk by the process of drying it may, as mentioned in the extract quoted, be something like a rat's tail, but even in the growing state it must be much more slender and equal in diameter. Usually the specimens are solitary, though sometimes two grow together as shown in our sketch. To this we may now allude. 1 and 2 form the subject of this notice. The original caterpillars are extremely hard and tough, almost chalky within, which is extremely curious when it is considered how soft they must once have been. The change, we imagine, has been wrought in great measure by the mycelium of the fungus. Besides being hard and dry they are of course much shrivelled, so that our drawing shows little of the form of the living caterpillar. The fungus is sometimes blackish, oftener of light brown colour. The position of the fructification is indicated at the top by a slight change in form and by the roughness of the surface. 3 is *Cordiceps Sinclairii*, the only other species recorded for New Zealand. It grows on the larvæ of an orthopterous insect, and, as is easily seen, is a very distinct species.

There are several very interesting near allies to the above. One attacks the wasp, and is called *Guepes végétales*. The fungus reaches its full development during the life of the insect, which is reduced to the last stage of debility. Another on a caterpillar is a celebrated drug in the Chinese pharmacopœia, used only by the Emperor's physician. It is said to have similar properties to the celebrated Ginseng; and we have record that Father Perennin was raised from a state of extreme weakness by its use administered in the most appetising manner of being dressed in the body of a duck.

SPIRÆA THUNBERGII.

ATTENTION was recently directed in our columns to the great value of this *Spiræa* for the decoration of conservatories during December and January. As was observed on page 68 this shrub was the principal feature in the beautiful conservatory of C. Seely, Esq., Furzedown Park, on the arrival of the family at their suburban residence about the middle of January. Fifty plants or more were then laden with thousands of their small white flowers, and the effect produced was as chaste as it was striking. We have since had inquiries relative to this

shrub, and one writer suggests that the plant referred to is *Spiraea crenata* and not *S. Thunbergii*; but on comparing the accompanying figure, which was engraved from a spray obtained from Furzedown, with the following description from Don's Botanical Dictionary, it will be perceived that the plant which is so successfully forced by Mr. Laing is rightly named. Thunberg's *Spiraea* is described by Don as "a shrub growing

3 to 6 feet in height; leaves linear-lanceolate, acuminate at both ends, smoothish, sharply serrated towards the apex; fascicles of flowers sessile, lateral, racemose in consequence of the leaves falling off; calyx glabrous. Native of Java and Japan. Flowers white."

It may be observed that the leaves are not shown as "sharply serrated" because the foliage was young, and in that state

Fig. 21.—*SPIRÆA THUNBERGII*.

resembles almost exactly that of the Stitchwort (*Stellaria graminea*), still the serrations are manifest, and the plant is no doubt *S. Thunbergii*. *S. crenata* is described by Don as having "leaves obovate, rather pubescent, crenulated at the apex; corymbs stalked; pedicels puberulous. Native of Spain, &c." Our correspondent may be right that Thunberg considered his plant as being a variety of *S. crenata*; but Linneus did not, neither did Siebold, who considered it distinct and named it *Thunbergii*.

Spiraea Thunbergii has been long known as a pretty early-flowering deciduous shrub, but its real value for quick forcing and conservatory decoration in the depth of winter has only been known to a few. The fact is now made known to many. How quickly it may be forced into flower and how long it continues attractive are testified by Mr. Laing. "Five dozen plants of *Spiraea Thunbergii*," writes Mr. Laing, "were lifted from the open ground and potted on December 21st. They were placed in an intermediate house having a temperature

of, 50° to 55°, and they were in full flower on January 14th. They are now (February 5th) still in full flower, and are likely to continue for another fortnight." It will be readily admitted that a plant so charming as this is, that can be potted from the open ground in December and be in full flower in three weeks and then continue attractive for five weeks, is an acquisition. Some of the plants were more densely covered with flowers than the spray now figured, and the flowers are as well adapted for wreaths and vases in rooms as the plants are effective in the conservatory.

Thunberg's *Spiræa* requires the same general culture as *Dentzia gracilis*, and is easily propagated by cuttings or division.

EARLY PEAS.

It appears from your columns that many doubts exist in the minds of some of your correspondents of the possibility of raising early Peas in the open ground without protection. I have grown early Peas for the last five years most successfully, and never once suffered the least inconvenience from frost. My mode of proceeding is as follows:—I make the first sowings about the 15th of November in the open ground (shelter of any kind I deem most pernicious), the drills being opened a few days previous with a draw hoe 9 inches wide and 1½ inch deep, with a space between the rows of 9 feet. The weather being favourable I prepare the seeds by steeping them for a quarter of an hour in pure paraffin oil previous to sowing; I then remove the oil and sow the seeds. In covering I take the adjacent soil with a spade and lay it evenly on the seeds, taking care not to disturb them, nor do I use the rake after covering. This done I have never felt the slightest inconvenience from rats or other vermin, though they are very numerous in this locality. As soon as the plants make their appearance above ground I apply very small stakes for support, after which I have each side of the row dug as deep as the digging fork will allow, permitting a little of the soil to drop in between the stakes. The deep digging has the effect of opening the ground and absorbing the superfluous moisture from the rootlets of the Peas, while the stakes keep the plants open. Even now I apply nothing for protection, as in my experience it interferes materially with the after-success of the crop. I can say without hesitation that young Peas will stand 20° of frost uninjured without the slightest protection. My early Peas are now 9 inches high, and wearing a most flourishing appearance, although the thermometer registered 16° of frost on two successive nights—viz., January 31st and February 1st.

The sorts I select for first sowings are Sangster's No. 1, Carter's First Crop, and Dickson's First and Best. I never fail to find those come in early in May. Laxton's Prolific and Laxton's Supreme, when sown at the same time, form a good succession.

My object in communicating these notes is to assure those who do not possess the conveniences of cold frames or other artificial aids that they can raise as good or even better crops of Peas without them.—A. CAMPBELL, *Muckross Gardens*.

On February 4th I sowed four boxes of Dickson's First and Best, and three boxes of William I.; the boxes are 2½ feet long, 4 inches deep, and 10 inches wide. They are placed in a cold pit under glass; no fire heat is given to them. They are planted out on a warm south border early in March. The stakes are put to them as the planting proceeds. When all is finished a net is carefully stretched over them, keeping them safe from the sparrows. The crops will be all gathered by the third week in June, and the ground planted with Celery; and on the Celery ridges are planted Lettuces, Little Pixie Cabbages, and Cauliflowers. By the time the Celery is ready for earthing-up all those intermediate crops will be used. The Celery is never earthed-up until it is full grown. This system having proved so satisfactory with me, I have not sown a Pea in the autumn for nearly sixteen years.—RICHARD NISBET, *Ascarby Park Gardens*.

THE AURICULA WOOLLY APHIS.

I HAVE so often told my tale of woe in the Journal that I had secretly determined I would not mention the nasty subject again, but Mr. Llewelyn's letter compels me to break silence, for like him I am again a sufferer. I commenced top-dressing last week, and the length of my face may be more readily imagined than described when the first plant that I operated upon was choked all round the collar by the beast.

I thought to myself, Well, I must give up Auriculas. Happily it was not so bad. I went on dolefully, but as yet I have only found the aphid bad on three plants, and slight in a few others; but still there it was, and I can only account for it by supposing that some nidus must have been left in the crevices of the collar which has developed itself since. I adopted more heroic measures than Mr. Llewelyn, for I turned the plants completely out, brushed collar and roots with a tolerably hard brush, and repotted them. Of course this destroys the hope of a bloom from them; but if I can save my collection I shall be only too pleased. I shall of course watch carefully and see whether it appears again.—D., *Deal*.

HINTS ON GROWING VEGETABLES.—No. 3.

SEED SELECTION.

ANOTHER important point in which the note-book and garden plan spoken of on page 88 prove useful is in aiding us to choose our seeds for another year. Whilst we are sitting by our fire listening to the rain with the pleasant reflection that, whilst the sound adds to our sense of comfort indoors there are plenty of 3-foot drains carrying it off our borders, we can arrange our crops for the coming season, for we know exactly how many square yards of ground there are in any particular quarter, and if we find it necessary to increase the production of any vegetable our plan enables us to tell immediately how much room we can spare and the quantity of seed we shall require. Are we puzzled by the multitude of names and the commendations of each variety which we find in our seedman's catalogue? Our note-book will come to our assistance, and will tell us what kind does best in our soil and what we may rely upon for the future, and so saves us much hesitation now, and disappointment in summer. In all gardening matters, but more especially in the choice of varieties, there can be no fixed rule for the whole country. "What is one man's meat is another man's poison" is true here, and each must choose and select for himself to suit his soil, his climate, and last, but not least, his demand. But though this is certainly the case with fruits, it is not so much so with vegetables, and therefore I venture to give a list of seeds I am ordering this spring, with the reminder that my soil is stiff clay, with late cold springs and early dripping autumns.

Beet.—Dixon's Select Crimson.
Dwarf French Beans.—Negro Long-podded.
Borecole.—Cottager's Kale and Rosette Colewort.
Broccoli.—Autumn.—Walcheren. *Winter*.—Snow's Winter White. *Spring*.—Cattell's Eclipse and Suttons' Late Queen.
Brussels Sprouts.—Scrymger's Improved.
Cauliflower.—Early London and Walcheren.
Cabbage.—Early York, Wheeler's Cocoa-nut, and Dwarf Elm Savoy.
Carrots.—Early French Horn and James's Intermediate.
Celery.—Dwarf Sandringham White and Williams's Matchless Red.
Cucumber.—Telegraph. *Melon*.—Little Heath.
Lettuce.—*Cos*.—Bath Imperial (black-seeded), and Paris White. *Cabbage*.—All the Year Round.
Onions.—White Spanish and James's Keeping.
Peas.—*Early*.—Dixon's Best Early,* Improved Sangster's No. 1, William I.* *Mid*.—Laxton's Fillbasket,* Laxton's Supreme, Dr. Maclean,* Sandford Green Marrow.* This is a most splendid Pea, a very heavy cropper, and excellent in flavour. Can anyone tell me where it can be obtained, as I procured my stock from a private source, and am nearly out of it? *Late*.—Emperor of the Marrows,* Veitch's Perfection, and Laxton's Omega.
Radishes.—Long Scarlet, Turnip, and French Breakfast.
Potatoes.—Myatt's Prolific. *Parasit*.—The Student.
Turnips.—Early White Dutch and Orange Jelly.
Vegetable Marrow.—Long White.
 The above will prove quite sufficient for a medium-sized garden. The Peas marked with an asterisk are specially recommended.—A YORKSHIRE AMATEUR.

SPARMANNIA AFRICANA.

I DO not wonder at Mr. Iggulden's question—"Why is it that we so seldom meet with or see mention made of this plant?" I read the notes on page 91 with much pleasure, for I have been growing the same plant, comparatively speaking, in ignorance. Last summer I had a few plants given to me which had evidently been starved in 48-sized pots; they were

shifted into pots a size larger, and placed outdoors with other greenhouse plants. The *Sparmannias* certainly did not make much progress with this treatment; but, however, I placed them in a greenhouse in the autumn, and they soon began to show signs of flower even in this cramped and starved state. Each of these plants has now four and five trusses of flowers open and about to open. A more pleasing greenhouse plant at this season I do not know. I shall certainly adopt the mode of culture recommended by your correspondent. I hope to hear more about this useful greenhouse plant, for I am sure it is very valuable for winter decoration.—J. P.

ORCHIDS AT KEW.

THE Orchid house at Kew is now very attractive, there being many beautiful and interesting species in bloom. Amongst the most noteworthy that arrested our attention on February 5th are the following:—

Angræcum eburneum and *eburneum virens* are strongly represented. These species are admirably adapted for large houses, but where only small collections of Orchids are grown they are scarcely to be recommended. *Ansellia africana* is in flower, also on the side stage of the warmer compartment may be seen some recently imported plants of a splendid variety; the pseudobulbs are much shorter and stouter, the flowers are larger and brighter-coloured, and have not the dull appearance of the type. *Ania latifolia* has light brown petals with a creamy white labellum, but is not at all showy. *Barkeria Skinneri* is in flower in the cool house; it flowers from the extreme points of the deciduous pseudobulbs. The flowers are of a dark purple colour, very pretty, and last a long time in good condition. This *Barkeria* is not nearly so popular as it deserves to be, and I think no collection would be complete without one or more plants.

The *Cattleyas* are now making a grand display. Of *C. labiata* there are several varieties, all varying somewhat in colour from pure white to dark rose. The flowers of *C. Lindleyana* are beautifully marked, though not altogether very showy. *Cypripediums* are numerous, and are represented by *C. insigne*, *insigne Maulei*, *biflorum*, *venustum*, *barbatum*, *longifolium*, *Roetzlii* with four long flower spikes, *Harrisianum*, *Sedeni*, and *Schlimii*, which is a little gem; the flowers in shape and colour resemble very closely the hardy *C. spectabile*. *Cœlogyne cristata* in the cool house is now sending up numerous flower spikes, and when the flowers are fully expanded they will be greatly admired by many a passing visitor.

Dendrobiums are now strongly represented, the beautiful rich colours are almost dazzling to the eyes. *Dendrobium crassinode* growing in a basket suspended from the roof is looking very gay; the sepals and petals are pure white, tipped at the ends with light violet, and so also is the labellum, with, besides, a large yellow blotch. *D. Freemani* is beautifully in flower. It is one of Mr. Bull's introductions, and apparently is a variety of *D. lituiflorum*, to which it is referred by Reichenbach. It was named in honour of its discoverer in Assam. The pretty *D. Devonianum* is flowering freely on blocks of wood suspended from the roof. This is one of the few *Dendrobies* having a lip so deeply fringed. *D. Wardianum* is flowering profusely from well-ripened deciduous pseudobulbs, and too much in its favour cannot be said, as the flowers may be used to great advantage in several ways. *D. barbatulum* has pure white flowers which proceed from the points of the pseudobulbs. *D. densiflorum* and *fimbriatum* are also in bloom; the former has beautiful yellow flowers, the latter is of a darker yellow, with a large dark blotch at the base of the labellum. The two last-named species are a great contrast to their surrounding brethren of several colours.

Dendrochilum glumaceum is extremely graceful with its drooping flower spikes: in the warmer compartment may be seen a very fine specimen, and heavily laden with bloom. The individual flowers are not very showy, but when produced on a spike almost as close as they can possibly grow they have a very pleasing effect, and that which makes the flowers more appreciated is their delicious perfume.

Epidendrums are not at all showy with the exception of one or two species; but one that is very much admired at Kew is *E. xanthinum*, which is of beautiful golden yellow. *Lycaste Reichenbachiana* has light green sepals and pure white petals; the labellum, which is also pure white, has a beautiful row of fringe round the margin, giving the plant quite an unique appearance. *L. gigantea* is much in the same way as the last

as regards shape of flower, the lip being of a dark brown colour. *L. macrophylla* is also in bloom. *Masdevallias* are few, this genus being represented by one solitary species, *M. ignea*. I had almost overlooked *Mesospinidium aurantiacum*, or what, perhaps, would be better known to the Orchid world as *Ada aurantiaca*, which is very pretty, and the colour of its flowers is so seldom met with in Orchids that we must certainly give it a good word. The individual flowers in this species are not very attractive in themselves, but when one beholds a flower spike a foot or more in length it then makes together quite a display.

There are several *Odontoglossums* in bloom, of which the following are the best. The first on the list is our old and highly esteemed friend *O. Alexandra*, which is always appreciated when in flower; *O. pulchellum* and its varieties are charming, the single flowers look so much like Lily of the Valley at a distance; *O. Pescatorei* is so closely allied to *Alexandra* that it is difficult to distinguish between them; *O. cordatum* and *O. gloriosum* are well worth growing; a plant of *O. Bictonense* at the end of the cool house is producing nine long spikes of flowers. There are several forms of *Oncidium aureum*, all varying some little in size of labellum, which is of rich golden yellow; *O. cheiroporum* is very compact in growth and free-flowering, and is always welcome; *O. cucullatum* is extremely pretty, the lip being of a light lilac colour, beautifully spotted with dark crimson; *O. ornithorhynchum* is one of the most dwarf-growing of all the Orchids, and produces very pretty flowers, but which unfortunately are anything but agreeably scented. We now come to the most lovely genus of all Orchids, *Phalenopsis*. *P. Schilleriana*, *P. amabilis*, and *P. rosea* are those flowering at the present time, the former with strong branched spikes of bloom. *Stenorrhynchis speciosa* is evergreen and terrestrial, requiring a liberal supply of water at all seasons. The flowers are produced on stems a foot or 18 inches long, and are bright rose in colour. Even when the plants are not in bloom the foliage is always handsome.

Trichopilia sanguineolenta, better known to Orchid-growers as *Helsia*, is now very attractive, and its labellum is in contrast to the sepals and petals just as occurs with *Zygopetalum Mackayi*, the lip in each case being attractively veined, while the other parts of the flower are dull-coloured. In addition to the above are many of lesser importance, to which we might refer had we not already so long a list.—W. G.

NOTES AND GLEANINGS.

COL. TREVOR CLARKE writes to us as follows on **FLOWERING LILIUM THOMPSONI**:—"After reading my friend Mr. George Wilson's description of the method employed by the distinguished liliologist Herr M. Leichtlin to produce the flowering habit in *Lilium Thompsoni*, I deprived five plants of their offsets during the growing period, using for the purpose a pointed stick. The leaves were preserved, however, or the greater part of them. Those five plants are now, every one of them, throwing up healthy flower stems."

—We have received the schedule of prizes to be competed for at the PROVINCIAL SHOW of the ROYAL HORTICULTURAL SOCIETY, to be held at Preston from July 10th to the 13th inclusive. The classes number one hundred exclusive of those for implements, &c. The prizes are sufficiently liberal to command good competition. In the open class for sixteen stove and greenhouse plants the amounts offered are £30, £20, and £10. In the amateurs' section the chief prizes are £20, £15, and £10 for twelve stove and greenhouse plants in bloom; £12, £7, and £5 for twelve plants, six to be in bloom; £10, £7, and £5 for six plants; £20, £15, and £10 for twelve Orchids; £10, £7, and £5 for six Orchids; £12, £8, and £7 for nine fine-foliaged plants, and similar amounts for the same number of Ferns. The nurserymen's section opens with £25, £20, and £15 for a group of one hundred miscellaneous stove and greenhouse plants, space not to exceed 250 superficial feet, artistic arrangement to be considered in judging. A corresponding class for one hundred hardy plants is apportioned £20, £15, and £10; £15, £10, and £7 are provided for twelve new and rare plants not in commerce; and £12, £8, and £6 for new plants sent out in 1876, 1877, and 1878. For twelve stove and greenhouse plants in bloom £15, £10, and £6 are provided; for twelve Orchids, £15, £10, and £7; for twenty Conifers the awards are the same as for Orchids; and for twelve specimen Clematises the amounts offered are £12, £10, and £7. The chief prizes in the fruit section are £15, £10

and £5 for a collection, and £5, £3, and £2 for a collection of not less than ten varieties of Strawberries. Prizes are also offered for Grapes, Pine Apples, and other fruits. Nine classes are provided for vegetables, seven for Roses, and about twenty for the productions of cottagers and artisans. Gold medals are offered for the best stand of horticultural implements and appliances, and for the best exhibition of horticultural buildings and structures. Nine silver medals are also provided for separate horticultural implements specified in the schedule. Liberal prizes offered by Mr. Bull, Messrs. James Carter and Co., Messrs. Sutton & Sons, and Messrs. James Veitch & Sons, will be competed for on the same occasion.

— AT the ordinary meeting of the ROYAL HORTICULTURAL SOCIETY to be held on the 19th inst., Mr. Jennings will address the members on "The Cyclamen—its Cultivation and Classification."

— A SUCCESSFUL meeting of gentlemen and gardeners was held in the National School, Putney, on the evening of the 8th inst., for the purpose of establishing a CHRYSANTHEMUM SOCIETY FOR THE DISTRICT OF PUTNEY, FULHAM, AND WANDSWORTH, for "promoting the superior cultivation of the Chrysanthemum and other flowers and fruits." The chair was ably occupied by the President of the Society, Baron Pollock, who, after alluding to the fertile soil of the Thames valley and the general excellence of the crops, complimented the numerous gardeners on their attendance, and promised to aid them in carrying out their object, which he felt was a worthy one. An excellent code of rules was submitted to the meeting, and, subject to a few alterations, was passed. The movement—which was originated by Mr. Pithers, Mr. Whittaker, and a few other gardeners—has met with a considerable share of support. Some influential gentlemen have consented to become Vice-Presidents, and a goodly number of gardeners have already been enrolled as members of the Society. Nearly fifty of these attended the meeting, and all appeared to be animated with the same feeling—namely, to make their new Society prosperous. As the district is a populous one, and as the rules do not exclude members from other localities subscribing, some good autumn exhibitions may be expected to result. Hearty votes of thanks to the Chairman and the School Committee terminated the proceedings. Mr. Moore, Richmond Road Nursery, Putney, is the Secretary.

— WE understand that T. Graveley, Esq., of Cowfold, Sussex, has kindly undertaken to act as Local Secretary for the NATIONAL ROSE SOCIETY for Horsham and neighbourhood; and that Capt. Edward Carter will act in the same capacity for Brighton and the neighbourhood.

— THE usual monthly meeting of the SCOTTISH HORTICULTURAL ASSOCIATION was held in 5, St. Andrew Square, Edinburgh, on Tuesday the 5th inst. There were over a hundred members present. The President occupied the chair. Thirteen new members proposed at the last meeting were duly admitted, and fifteen new names were proposed and seconded for admission as members. The subject for discussion was "Vine Borders," opened by Mr. W. Priest, Newbattle Gardens, by reading notes stating in a plain and practical manner his experience in their construction. He laid great stress upon having a depth of border, say from 2½ to 3½ feet, and sloping from back to front, and that the soil should consist of good loam, lime rubbish, crushed bones, and charcoal. The paper gave rise to an animated discussion in which many members took part, the general feeling being the principles advocated by the essayist were sound and thoroughly practical, but that gardeners would require to be guided by the circumstances of their individual case. During the discussion the experiments of Mr. Hunter, Lambton Castle, were adverted to. The proceedings terminated with a vote of thanks to Mr. Priest. The next meeting will be devoted to the annual election of office-bearers and business arrangements for the next year.

— THE report and schedule of the RICHMOND HORTICULTURAL SOCIETY afford gratifying evidence of past prosperity and give promise of future success. The funds of the Society have steadily increased since its establishment, and each succeeding exhibition has been better than before. The Society is fortunate in being established in a populous and prosperous district, also in receiving the active support of the resident gentry. This is evidenced by the long and influential list of donors to the special prize fund, which is headed by H.S.H. the Duke of Teck, the President of the Society. The fourth Exhibition is to be held in the Old Deer Park on June 27th. The prizes offered are on a liberal scale, especially those

provided in the division for exhibitors beyond the limits of the Society's district. A new feature is established of offering gold, silver, and bronze medals of specified value, the exhibitors to have the option of taking the prizes in medals or money. In the division limited to exhibitors in the Society's district the classes are numerous and the prizes substantial; and good provision is made for cottagers' products. In addition to the Society's prizes and the special prizes provided by upwards of thirty ladies and gentlemen of the district, Messrs. James Carter & Co. offer a silver cup for a collection of vegetables, and Mr. Turner, Slough, provides silver medals for Roses and Carnations. Liberal prizes are also offered by Messrs. Sutton & Sons for Cucumbers and Melons, and by Messrs. Rollisson & Sons for Orchids.

— THE supply of BROCCOLIS IN LONDON is now very great; piles of splendid heads are seen in almost every green-grocer's shop and on costermongers' barrows. The mild winter has doubtless contributed to the full and early supply of this esteemed vegetable.

— As a tribute of esteem to Mr. J. P. Allan, who has recently become a partner in the well-known firm of Messrs. Stewart and Mein of Kelso, his many friends in the district invited him to a dinner, which was largely attended. The chair was occupied by Mr. Wemyss, gardener to Sir G. H. S. Douglas, Bart., supported by Mr. Fowler, gardener to Lord Polwarth, and Mr. J. M. Mitchell of Kelso. The Chairman spoke in flattering terms of the great professional ability and activity of Mr. Allan, and the compliment was suitably acknowledged. The name of the firm will in future be Messrs. Stewart, Mein, and Allan.

— THE *Australasian* states that the PHYLLOXERA VASTATRIX has appeared in Australia. This is a great misfortune, since colonial wines are making their way in Europe, and Grape-growing is becoming an important industry at the antipodes.

— AN amateur, writing to us on PARAFFIN LAMPS FOR EXCLUDING FROST, states that he has employed one for three years in his small greenhouse with great satisfaction, and he would not hesitate if required to place a smaller lamp in a frame. He describes the reservoir of the lamp, which is of block tin, as resembling an inverted soup plate. This forms the base and supports a moveable cylinder a little more than a foot high and 6 inches in diameter, with an aperture at the bottom for the burner to pass through, and an ornamental lid at the top with apertures for the escape of heat. After the heat has been turned "full on" for a quarter of an hour the cylinder becomes quite hot, and is afterwards kept sufficiently so by a very small flame. If he "fires hard in severe weather" he places a shallow tin dish of water on the top in place of the lid. No injury whatever has resulted from the lamp, but on the contrary he has "two hundred Geraniums which have been preserved through the present winter at the cost of one gallon of oil."

— A CORRESPONDENT sends us the following extract from Hinchliffe's "Over the Sea and Far Away," 1876, p. 70, on LAPAGERIA ROSEA AT HOME:—"Near the copper-smelting works of Lota, a few miles south of Concepcion, Chile, among the headlands of the coast, 'are the haunts of the Copique or Lapageria rosea. In spite of its exquisite beauty and seeming delicacy it is said to be almost the only plant of any kind that can exist under the influence of the sulphurous smoke of the smelting house, and Dr. Cunningham mentions having seen it 'in a flourishing condition, winding round the skeletons of shrubs killed by the smoke.'" This suggests that this beautiful climber would be suitable for town greenhouses, owners of which might well try the plant in smoky districts.

WORK FOR THE WEEK.

KITCHEN GARDEN.

WHERE Carrots and Radishes are grown in frames sowings of those crops may be deferred until the end of the month, otherwise sow when the weather permits. We sow on borders at the base of a south wall: the borders are from 18 inches to 2 feet wide, and have a depth of about 6 inches of rich light soil. French Forcing and Early Nantes Carrot, French Breakfast and Wood's Frame Radish, are the best for this sowing. The walls being covered with fruit trees the blossoms of which are protected, the Carrots and Radishes have the benefit of the protection. Make a sowing in a similar position of Lettuce Early Paris Market, All the Year Round, Bath Cos Sugarloaf, and Hicks' Hardy White; Cauliflower Early London, Walcheren, and Veitch's Autumn Giant, which last is very valuable in late summer and autumn;

Brussels Sprouts, and Leeks. For general purposes Musselburgh is unsurpassed. Those growing Leeks for exhibition purposes will sow in gentle heat. In warm localities a sowing of Turnips may be made upon a narrow border at the foot of a wall with an east aspect; Early Snowball and Veitch's Red Stone are suitable kinds. In cold localities defer sowing until the end of the month or early in March. Plant Shallots and Garlic, also Potato Onions, when the ground is in suitable order. Take the earliest opportunity to sow Parsnips, Hollow-crowned Improved and The Student. Onions of the Tripoli varieties transplant on highly manured ground for forming large bulbs, those left in the seed beds being thinned as they advance will come into use early. Draw a little soil to the autumn-sown Peas and place sticks to them, filling in the bottom with small twigs. Advantage should be taken of the first mild sunny weather to plant out early crops of Peas which have been sown in turves, &c., under glass, placing sticks to them at the same time.

Forcing Department.—Sow Dwarf Kidney Beans either in pots or in beds. We depend upon plants in pots for the early supply, sowing at intervals of a fortnight. We employ 10-inch pots, which are three parts filled with turfy loam, placing six to eight beans equidistant about an inch from the side of the pot, and press them into the soil to a depth of about $\frac{1}{4}$ inch. More soil is added when the leaves are above the rim of the pot. The plants are moderately watered until coming into flower, when the supplies are copious, and when pods form liquid manure is given. They require a light airy situation in a house with a temperature of 55° at night, 65° by day, increasing to 75° and more from sun heat. Osborn's Forcing is dwarf and very prolific; Williams' Prolific is somewhat taller, and both are excellent for pots. Tomatoes raised early in the year will now be strong plants and growing freely. They give the most satisfactory crops when planted out in narrow borders where the roots are somewhat restricted, and if the shoots are trained to a trellis about a foot from the glass they afford an early and good supply of fruit. The back wall of a Cucumber house is a good place for securing an early crop, especially if the house has a half-span roof. Falling borders the plants may be grown well in 10-inch pots.

EARLY FRUIT GARDEN.

The pruning of Peaches and Nectarines must now be proceeded with. Early pruning is not desirable, as it tends, when the trees are secured to the wall, to forward the blossom. No time should now be lost in pruning these trees when the weather permits. Cut-out the old worn-out branches if too crowded, especially those having a well-disposed young shoot at their base for supplanting the one cut away. The main branches should be 1 foot apart, and the shoots upon them for bearing 12 to 15 inches distant. Shoots not over 9 inches in length will not require shortening; those of a foot or more to be cut to 8 or 9 inches and to a triple bud, making sure that the central one is a wood bud. In all cases a wood bud should be left at the extremity of the shoots. Central leading shoots may be shortened to 15 inches, and the side extensions cut back one-third their length, always cutting back to firm well-ripened wood. Dress the trees after pruning as a preventive against insects: 1 lb. of soft soap to a gallon of water, adding tobacco powder to bring to the consistency of thin paint, is a suitable mixture, applying it with a brush, taking care not to dislocate the buds. Secure the branches to the wall by tying or nailing. Vines upon walls to be pruned. Rather close pruning should be practised, as the wood at the base of the shoots will be more firm, the extension shoots being cut back to firm ripe wood. Plantations of Strawberries mulched in autumn with partially decayed manure should have the dung pointed in lightly with a fork, not going so deep as to injure the roots, removing any decayed leaves from the plants, and weeds, especially those of a perennial kind. Strawberries grown on the lazy-bed system should have the old decayed leaves removed and be top-dressed with short manure, pointing it in slightly where space permits.

FLOWER GARDEN.

Complete the arrangement for the summer bedding, so that a sufficient quantity of the particular plants required may be propagated. In open weather the planting of hardy edging plants and such as are required for panels may be proceeded with, such as *Cerastium tomentosum*, Gold and Variegated Thyme, *Ajuga reptans rubra*, *Sedums glaucum*, *lividum*, &c.; and *Saxifragas hirta*, *hypnoides*, *Aizoon*, *cordifolia*, &c.; *Stachys lanata*, *Arabis alpina variegata aurea*, and *Antennaria tomentosa*; also *Violas* from autumn-struck cuttings, of which Blue Bell, Royal Blue, Crown Jewel, and Vestal are superb. They prefer rather strong moist soil, failing that manure very liberally. Many failures happen with *Violas* through late planting and neglecting to pinch the early-flowering growths. Seeds of *Violas* sow, and Golden Feather *Pyrethrum*, the Cut-leaved (*Pyrethrum aureum laciniatum*) being a capital form, in pans or boxes, to be placed in gentle heat until the seedlings appear, then remove them to cold frames, admitting air freely, as they suffer from a damp confined atmosphere. *Verbena venosa* is a much-neglected plant, though one of the most enduring of bedding plants. Old roots may now be divided and seeds be sown in gentle heat, and good plants will be provided by May. Herbaceous *Lobelias* are not sufficiently cultivated. They

may now be divided and started in gentle heat. They do best in vegetable soil, and must be kept moist. *Gladiolus* of the *Ramosus* section plant for early blooming. Plant the corms 4 to 6 inches deep, surrounding them with sharp sand. Plant *Liliums* 6 inches deep. They delight in peat beds, doing well among thinly planted *Rhododendrons*. They have a fine effect in borders backed by evergreens. If dry bulbs are planted they should be surrounded with sharp sand. *Dahlia* roots plunge in gentle heat, where they will soon form young shoots, which when a few inches long should be taken off and potted singly. *Cannas* may be started in the same way, dividing the roots when growth has taken place. They do not come very true from seed, hence the necessity of division to ensure the stock true to name. *Mignonette* and *Sweet Peas* may be sown in pots to be placed in gentle heat, and after the plants are well hardened off plant them out for early flowers. Seed may also be sown in a warm situation outdoors. *Calceolarias* closely placed in frames or if wintered in boxes should have more room. To have good plants they should have 4 to 6 inches of space every way. Sow in heat *Phlox Drummondii* and double dwarf *Scabious*, also a few German Ten-week Stock and *Asters* for early flowering. Pot off autumn-struck cuttings of *Pelargoniums* and other bedding plants which it is desirable to have strong by planting-out time. Tricolor and choice *Pelargoniums* should have an increase of temperature, say 50° at night, to promote the growth of cuttings, which may be cut about half way through beneath a joint and left on the plants for ten days to form a callus, and then be severed and inserted singly in small pots, placing them on shelves near the glass. *Roses* and other climbers against walls should be pruned, trained, and tied, and if an early bloom of *Roses* be wanted the standards or dwarfs of the perpetual class should be pruned at once, deferring the general pruning until a later period.

FRUIT HOUSES.

Pines.—Preparation should be made of the material for a fermenting bed to start early in next month suckers for the supply of fruit during the ensuing winter, spring, and early summer months; afford and maintain a temperature of 85° to 90° at a few inches from the surface. It is essential that the plants be as near the glass as possible. Soil for potting should be prepared, having it under cover to dry and become warmed. If the suckers be well matured at the base they do not require drying before potting, as the old-fashioned shrivelling process only serves to weaken them, but those not having the base matured should be detached for a few days before being inserted. If a few of the most forward plants were started late in the last or early in the present year they will now be showing fruit, and should be forwarded as expeditiously as possible, keeping the temperature at 70° , with an advance in mild weather of 5° to 10° , giving air as before advised. Examine them twice a-week, and water such as need it. Plants started early in the month must not be too rapidly pushed; 65° at night and 70° to 75° by day from fire is ample for the first month. The whole stock of plants should be gone over once a-week, as from the increased light their requirements of water will be increased.

Cherries.—Cherry houses are by no means so common as they deserve to be; indeed, only large establishments can boast of such structures. A lean-to house erected against a wall with a south aspect is suitable for Cherries, and it need not be more than 6 feet in width. The border should be thoroughly drained to carry off superfluous water. Road scrapings or grit of some kind must be added if the soil be too aluminous. Trees from the open wall between four and six years trained, if carefully removed to the house, come into bearing at once. Water them well to settle the soil about the roots, and ventilate very freely, syringing in the morning and again early in the afternoon, employing fire heat only to exclude frost; but when the trees are fairly in growth let the day temperature from fire heat be 50° to 55° , rising to 60° to 65° from sun, increasing the ventilation at 55° , and closing at that temperature, leaving, however, a little air on day and night; 45° to 40° at night from artificial heat will be sufficient. May Duke, Black Tartarian, and Elton are suitable for forcing.

PLANT HOUSES.

Stove.—The propagation of many plants may now be performed, among which may be mentioned *Gardenias*, *Rondeletias*, *Hibiscuses*, *Ixoras*, *Tabernæmontanas*, and others with firm wood. It is desirable to secure with the cuttings a heel—that is, a small portion of old wood, taking care not to bruise the bark. They must be inserted singly in small pots filled with sandy soil surfaced with silver sand, and be placed in a close frame with brisk bottom heat. *Hoya*, *Cyrtoceras*, and *Eschynanthus*, and similar plants strike readily from cuttings of the joints of the ripe growths; also *Eranthemums*, *Scutellarias*, *Centropogons*, and other free-growing plants, not omitting the very useful *Plumbago coccinea superba*. Cuttings of *Euphorbia jacquiniæflora* should be inserted for early flowering, selecting young shoots about 6 inches long taken off with a heel, also *Luculia gratissima*. *Begonia* cuttings of the stemmed kinds to be taken for flowering in late summer and autumn. *Allamandas*, *Bougainvilleas*, and other climbers may be increased by selecting young shoots 6 inches in length, and taken off with a heel and placing them singly in

small pots in sandy peat surfaced with sand. *Allamanda grandiflora* succeeds best when grafted upon stocks of *A. nerifolia*. *Epiphyllums* may now be grafted on *Pereeskia* stocks. Old plants which have ceased flowering should be repotted. Fibrous loam with a fourth of well-decayed manure and a sprinkling of sand with good drainage will answer; moderate pot room will suffice.

Orchids.—Potting and top-dressing as the plants afford signs of growth must be proceeded with. Drainage must be thorough, and the plants must be thoroughly cleansed of insects. White scale may be removed with a brush and a solution of soft soap, finishing-off with clear water. *Miltonias* do well in perforated pots or baskets, and as they require more heat and shade than the plants in the Mexican house generally, give them a place at the warmest end, suspending them from the roof. Good fibrous peat with a little sphagnum suits them. *Cattleyas* requiring fresh pots or blocks should be potted when they show new growths. In pots the plants must be slightly raised above the rim, and good drainage be given, using fibrous peat with lumps of charcoal for potting. They should be suspended from the roof, or kept near the glass where they can have plenty of light and a free circulation of air. This applies more particularly to such small growers as *C. Regnelli*, *C. Aclandiae*, &c. They require water about twice a-week, but should not be overdone. *Dendrobiums* starting into growth to have an increase of water, and be shifted into larger pots or baskets as the growth is fairly started. As the weather is brighter an increase of moisture will be necessary, sprinkling *Aerides* and *Vandas* lightly overhead, especially those recently repotted. Look after crickets and cockroaches, which are very fond of the young flowering growths, and destroy them by some beetle poison. Woodlice often destroy the young roots. Baits of a half potato raw with the centre scooped out may be placed on the surface of the pots and where the pests secrete themselves. Thrips must be kept down by fumigation with tobacco. Have shading in readiness, it need only be used to prevent scorching.

FLORISTS' FLOWERS.

Persian Ranunculus.—Beds which have been prepared during the autumn will be now ready for planting, and with us the ground seems to be in a better condition for the operation than it has been for the last two or three years. The 12th of February is generally looked upon as the orthodox time, but it has sometimes been March before we have been able to get the ground in order, and then only with very great trouble, owing to its being so very wet. Our own beds are 4 feet wide with boxed edgings, as this makes the planting (which is a matter of very great importance) more easy, for the *Ranunculus* ought to be planted about 1½ inch deep, long experience having shown that deeper than this the tubers are apt to reproduce small ones a short distance above the old one, and the growth is spoiled. We use a stout piece of oak about 4 inches wide with a notch 1½ inch cut in it at each end so as to fit the size of the bed. This is laid across and gently tapped with a mallet so as to make the drill the required depth, and then the tubers are gently pressed into the bottom of the drill. The *Ranunculus* likes a close bottom, and therefore the less the ground is worked in the spring the better. When the soil is at all heavy it is well to place in the bottom of the drill a little sharp sand, but our soil is light enough to dispense with this. A contemporary has mentioned some wonderful "French" varieties. As we have grown nearly all the kinds—Dutch, English, Scotch—we are surprised that we have never heard of this strain, and should be glad if any of the readers of the Journal could tell us anything about it.

Tulips.—The winter has been a propitious one, we should imagine, for this once favourite but now greatly neglected flower. The wet has not been excessive and the frosts slight, and it is these two combined which are so injurious to the Tulip. The wet readily lodges in the somewhat concave leaf, and then when frost supervenes it is apt to cause canker and decay. Where beds have been protected it will be time to take the protection off, and in fine weather the surface may be gently stirred, and if any signs of canker show themselves on the roots it should be cut away.

TRADE CATALOGUES RECEIVED.

H. Cannell, Swanley, Kent.—*Illustrated Floral Guide*.
Harrison & Sons, Leicester.—*List of Choice Seeds for the Garden and Farm*.

Charles Kilminster, Burgess Hill, Sussex.—*Descriptive Catalogue of Choice Flower and Vegetable Seeds*.

Laurence & Strike, 63, High Street, Stockton-on-Tees.—*Descriptive Catalogue of Flower, Vegetable, and Farm Seeds*.

J. T. Rote, Broomfield Nursery, Cecil Road, New Town, Enfield.—*Catalogue of New and Select Kitchen Garden, Agricultural, and Flower Seeds*.

Edmondson Bros., 10, Dame Street, Dublin.—*Spring Catalogue of Select Seeds, Roots, and Implements*.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or

Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

BOOKS (Jean).—There is an essay on perspective in Chambers's "Educational Course," and Hayter's "Introduction to Perspective," both good.

AMATEUR (Letter Carrier).—As you reside with your parents and are not a labourer we think you should exhibit in the amateur classes.

SCYTHE (G. M.).—It is not an implement of modern invention. It is described in Roman books still extant, and specimens have been found buried in this country. This in one instance occurred at Chesterford. The scythes were longer and more curved than those we use.

CLERODENDRON BALFOURIANUM (W. M. G.).—We presume your fernery is heated and is kept at a moderate stove temperature. If so the *Clerodendron* will "luxuriate and afford shade" during the summer. In our stove fernery it not only affords shade but a supply of flowers, and is never attacked by insects.

SCRIM CANVAS (Cranfordian).—It can be obtained we think from any of the leading nurserymen and seedsmen.

APPLE TREES CANKERING (A Country Vicar).—A light soil on ferruginous subsoil is very liable to induce canker. The best preventive is to keep the roots near the surface, which is best effected by keeping it well mulched with stable manure.

GUM FOR FLOWERS (A Many-years Subscriber).—To check the fall of the petals drop into the centre of each flower a strong solution of gum arabic. Any druggist can supply you. Apply to the nearest florist for *Asters* suitable for pot culture. They are very numerous and mostly unnamed.

LIQUID GLUE (Solvent).—We have never tried it; but the receipt was supplied by a very competent authority to a scientific journal from which it was taken.

SOIL FOR FIGS (An Ignoramus).—If you have a very fertile rich loam you need wish for nothing better for your Figs in pots. If it is poor enrich it with about a third of decayed manure to two-thirds of the loam; a sprinkling of mortar rubbish and charcoal is also beneficial. Be careful to drain thoroughly and to ram the soil hard. The spray of the plant enclosed was too much withered for identification.

ROSES FOR A SMOKY NEIGHBOURHOOD (Maud).—The best advice we can offer you is to plant only robust-growing and free-flowering sorts, and of such we may name *Gloire de Dijon*, *Charles Lefebvre*, *Baronne de Rothschild*, *La France*, *Annie Wood*, *Beauty of Waltham*, *Victor Verdier*, *Comtesse d'Oxford*, *Centifolia rosea*, *Charles Lawson*, *Boule de Neige*, *Dr. Andry*, *John Hopper*, *Jules Margottin*, *La Ville de St. Denis*, *Madame Alfred de Rougemont*, *Louisa Wood*, *Marchal Vaillant*, *Marquise de Castellane*, *Maurice Bernardin*, *Monseigneur Noman*, *Monsieur Paul Neyron*, *Paul Verdier*, and *Pierre Notting*. Any of this choice two dozen answer well in pots, and for the open garden we would add *Mrs. Bosanquet*, *Provins Cabbage*, common *China*, common *Moss*, with white *Perpetual Moss*, *Salet*, and *Madame Moreau*. As you wish for early and late bloom we add half a dozen *Tea Roses*, to be trained to any wall or building:—*Cheshunt Hybrid*, *Homère*, *Narcisse*, *Madame Falcot*, *Souvenir d'un Ami*, and *Duchess of Edinburgh*.

PLUNGING MATERIAL IN A PROPAGATING FRAME (F. J.).—With a brisk heat we prefer keeping plunging material moist, for if dry it must absorb moisture from porous pots to a considerable extent, to the great risk of harm to the cuttings.

TIME REQUIRED TO FORCE RHUBARB (Idem).—Your Rhubarb will be fit for use in a month or six weeks from the time of starting. Much depends upon the quantity of fermenting material applied. Gauge the heat with a trial stick occasionally. If it is unpleasantly hot to the hand there will be risk of destroying the crowns, and some of the heap must be taken away. A gentle heat is in every way preferable, the growth being stronger and the roots are less exhausted.

LATE PEAR AND PLUM FOR A WEST WALL (G. W. Mune).—Winter Nellis Pear and Bayley's Green Gage Plum; or, if your prefer a red Plum, *Kirk's*.

TREES FOR A SCREEN (Idem).—If you require a fast-growing deciduous tree the Black Italian Poplar will suit you, and it may be pollarded as you propose. But as your screen is to be only 12 feet high, why not choose an evergreen, such as *Portugal Laurel* or *Holly*? Both of them may be cut and clipped to a formal hedge, or may be left uncut to form specimens of large size and elegant proportions. The mop-headed *Acacia*, *Robinia inermis* forms handsome miniature standards.

PROPAGATION OF MANETTI ROSE STOCKS (W. S.).—Cuttings are made in the autumn in lengths of a foot of the firm well-ripened growth of the current year, the bottom being cut across close below a bud, and the top cut slant an inch above a bud. The bed requires no shelter, and therefore the cuttings are inserted in any convenient border of fertile well-drained soil, being thrust in deeply, leaving only about 4 inches of the top above the surface. The rows are a foot apart, and the cuttings 6 inches apart in the rows. This process may be carried out successfully throughout the winter; but not a day should now be lost, as chances of success will decrease proportionately with the swelling of the buds. You may not be aware that strong plants of *Manetti* may now be had for 1s. 6d. a dozen and 8s. a hundred.

ASPECT FOR MARECHAL NIEL ROSE (Idem).—A south or south-western aspect is best, as the cold north-eastern blasts, which have been so prevalent in the last three or four springs, prove fatal to the large foliage, especially in its then tender condition, and are also hurtful to the blossom.

REPOTTING EUPHARIS AMAZONICA (G. B.).—Repot in rough rich soil consisting of turfy loam, old decayed manure, with a plentiful admixture of sand and powdered charcoal. Let the whole of the bulb be below the surface, employ large pots, plunge in a brisk bottom heat, water freely, and apply also frequent doses of liquid manure after the pots have become filled with roots. Thus much for pot culture. For obtaining a supply of cut flowers—and who does not covet such a supply?—discard the pots and plant out in the bed of a stove, letting the roots ramble at will, and you will have flowers in greater abundance and finer than in pots.

INSECTS ON BIGNONIA (A Devonian).—The spray sent is infested by both brown and white scale. Wash the foliage and stems with a strong solution of soft soap or Gishurst compound, dissolving 3 or 4 ozs. in a gallon of water and applying at a temperature of 120°. Occasionally *Camellias* will produce a white spray when the plants are in a healthy state, but the leaf sent suggests that the root-action of your plant is imperfect.

TIME REQUIRED TO BRING POTATOES TO MATURITY (*Country Vicar*).—Under good culture early Potatoes are fit for table in eight weeks from the time of planting; that is to say, if you plant in the second week of April they will be ready in the second week of June. If you plant earlier you gain nothing and have to wait so many more weeks from the time of planting. Second early sorts planted at the same time will be ready a fortnight later, say the first week in July, and late kinds will not be ready till the second week in August, or sixteen weeks from the planting—just double the time of the early sorts. Early and second early sorts continue good for about four months, and the best late sorts are in excellent condition for ten months. We have had Paterson's Victoria really good the year round.

IRISH YEW SEEDLINGS (*Idem*).—Irish Yews will of course come from seed, but, owing to its scarcity, they are usually raised from cuttings, which strike root so freely as to render this particular sort a favourite with propagators. You say your common Yews have innumerable seedlings springing up beneath them, and yet you have no seedlings from the Irish Yew. We have a huge old Yew tree under which fowls run, and not a seedling is there to be found. We have occasionally found a few seedlings of Irish Yews in our shrubberies, but the seeds do not appear to germinate in this natural manner nearly so freely as those of the common Yew.

TREES ON THE CHALK (*A Lady*).—Much depends upon the depth of soil overlying the chalk. We have seen fine Elm and Oak trees in deep soil upon chalk, which is perfectly innocuous to any of our hardy trees. As therefore your soil is unlikely to be of an uniform degree of thickness, you may find upon examination that you have suitable situations for other deciduous trees besides Beech, which with Yew, Silver Fir, and most of the Conifers answer well in a shallow soil. Avoid Wellingtonias, which require a very deep rich soil; the Silver Fir, on the contrary, grows 100 feet high in thin poor soil. Pinus insignis is another fast-growing Conifer with a dense clothing of long foliage of a pleasant lively green hue. Of other Conifers take Cedrus Deodara, C. atlantica, Picea Pinsapo, P. Nordmanniana, Cupressus macrocarpa, and C. Lawsoniana erecta viridis; and of deciduous trees Wild Cherry, Robinia hispida, R. Pseud-Acacia, the double-blossomed Cherry, the Tulip Tree, Oriental Planes, Sycamores, and Limes. The trees may be transplanted of a large size, but it is a costly process, likely to prove unsatisfactory without the exercise of much care subsequently. Shrubs may now be transplanted with perfect safety onwards for another month.

HERBACEOUS FLOWERS ON THE CHALK (*Idem*).—Enrich the soil thoroughly with manure or leaf soil, and you may plant your collection with confidence of success. If the situation is exposed to gales some shelter for tall-growing plants is desirable, otherwise aspect is immaterial, unless you intend trying experiments upon so-called tender plants, then a snug sheltered position upon to the south or south-west would be desirable.

NAMES OF FRUIT (*W. Potten*).—The small Apple is Birmingham Stone Pippin. The larger one is not known. (*J. A. B.*).—Rymer. (*Tillington*).—1, Hoary Morning; 2, Golden Pearmain; 3, Not known, probably local; 4, Wheeler's Russet; 7, Sheep's Nose.

NAMES OF PLANTS (*J. P.*).—*Oeanthus asureus*. (*W. W.*).—A good variety of *Tydena*.

THE HOME FARM: POULTRY, PIGEON, AND BEE CHRONICLE.

THE MANAGEMENT OF DOWN EWES AND LAMBS.

(Continued.)

We will take first into consideration the best plan to pursue having determined to fatten the ewes and lambs together; and in order that the ewes may be fat and fit for the butcher when the lambs are sold, it requires very liberal feeding as well as great nicety and care in the feeding. Irrespective of any other advantage in fattening the ewes at the same time as they are suckling their lambs, we will introduce a common observation that "fat ewes make fat lambs." Our long experience proves the truth of this observation, and have found that the high feeding of the ewes is justified by the fact of the lamb benefiting greatly through having a supply of the richest milk. In our last week's statement we brought the management of the lambs down to a period when they are to enter upon root-feeding in the open field. The ram lambs will now require to be cut, and we have found this much the better plan than that of drawing at a few days or a week old. We prefer to cut and sear the lambs at about a month old, because we find that when treated in this way they are fuller in the leg and more fleshy on the back. We do not find that more lambs suffer or die after the latter operation than the former; but in either case they should be allowed a clean-littered fold the night succeeding the operation.

Before commencing root-feeding, whether of turnips, swedes, carrots, or mangel, they should be pulled, cleaned, and heaped in readiness for the cutter a week or ten days in advance. We have sometimes known frost continue long enough to disarrange our plans unless the roots are previously prepared for use in advance of the sheep. In commencing feeding on roots we prefer to begin at the lowest part of the field where the land is undulating, for we find that the lambs draw through the lamb gate better,

and the ewes are fond of lying on the highest ground, so that on the shifting of the hurdles the land is more regularly manured than when folding down the incline. The making of the lamb gate, too, is somewhat important, in order that there may be no danger of the ewes passing through into the lamb fold in advance; and this is secured by the bar across, the ewes being so much deeper in the bogom than the lambs. The moveable bar when adjusted to the bosom of the lambs entirely excludes the ewes, the rollers being also adjustable as the lambs grow larger.

We will now refer to the food for the lambs and the time of feeding. Great and valuable changes have been made in this matter within the past few years, for instead of allowing the lambs to run into the roots in advance and eat off the greens, the plan is now to feed the lambs entirely on trough food, and this can be easily done when the roots are heaped beforehand. It is also extremely important that the best and finest hay should be used cut into chaff. For this purpose grow white Dutch and yellow suckling clovers mixed, and when grown without rye grass and properly secured we have had this sort of hay as fine and handsome as a sample of hops, and to this there is no waste, for if any is left in the troughs it is removed to the ewes' fold. To make a lamb in perfection we require white Belgian carrots. We cut them into pieces about 2 inches long, and then pass them through Gardener's turnip cutter twice; they are then reduced in size and shape like dice. The best American cake meal is then strewn over, which readily attaches to the cut carrots, the aroma from which is very pleasant and grateful, and induces the lambs to eat at the earliest possible period. At the same time, instead of eating carrots only they are obliged to eat the cake also. After the lambs attain to about six weeks old we use bean meal as well as cake meal, in order that as they advance towards maturity they should be full of flesh as well as fat, and handle firm. This root-feeding may be done in open troughs, but in the covered troughs we feed with maple peas cracked, mixed with cake broken fine, and in pieces about the size of the cracked peas. After the lambs grow older we use cracked beans instead of peas, always taking care to place the covered troughs with the back to the wind; the young lambs, going there oft-times for shelter, are induced to begin feeding sooner than they otherwise would do. The lambs should be first fed when the shepherd arrives at the fold; they are thereby induced to draw away from the ewes, as it is not desirable for them to feed together. The rotation of feeding is hay-chaff three times a-day and roots twice; but the covered troughs should never be vacant, yet they should be cleaned-out once a-day. It has been observed by some of the best shepherds that to make good lambs they should never see an empty trough; and in removing the remains of lambs' food, whether of roots, hay-chaff, or beans, it is without waste, being given to the ewes. By this mode of feeding the lambs attain the earliest maturity, and as they are whilst young very small eaters the object is to induce them to take into the system food containing the greatest amount of nutrition.

Within the smallest space on this mode of management the general health of the lambs will be good; the changes of the weather make little or no difference to them, the condition of the food being always the same when frost, or snow, or rain prevails, but this cannot be said of lambs when they are allowed to run forward into turnip greens. We make no difference in feeding the twin lambs, simply because we cannot devise a higher or better system of feeding. We have, however, sometimes fed their mothers with a greater allowance of cake, but their lambs run forward with the others, although the ewes, if we have many with twins, have a separate fold. Upon this system of feeding we find that the lambs will be fit for the butcher at eleven or twelve weeks old, but may sometimes be kept longer with advantage, for being made heavier they make a proportionate higher price. When the stock of carrots fails, or by loss of the crop, we find the next best food is cabbage with firm white hearts. These, when quartered into the cutter and passed twice through, will be found very good feeding, and with the meal attached the lambs will eat

it very readily, as the leaves when cut are thin, and young lambs in particular will take them before any roots in larger pieces. Mangel we discard altogether as food for lambs, not because they do not possess feeding value, the Yellow Tankard variety being especially nutritious; but we find that the wether lambs after they get fat often suffer from stoppage of urine, for which there is no cure, as it cannot be seen until the system is so affected that they cannot be relieved. This has proved to arise from the deposit of sugar in lumps in the urinary passages. If they are killed they are of no use as human food, the whole of the flesh becoming impregnated with the urine.

We will now explain our method of feeding the ewes, so that they may be fat and fit for sale when the lambs are ready for market. As before stated, the roots—whether of turnips, swedes, mangel, or carrots—will be prepared ready for cutting with Gardener's cutter beforehand, the ewes being fed in troughs. When the roots are large they should be quartered into the cutter; there will then be no pieces after passing through the cutter, and this is a matter of consequence when cake and bean meal is mixed with the roots. When there are long pieces they take them into their mouths, and because they cannot eat them readily drop them outside the troughs, which wastes the food. The ewes should have half a pound of cake meal a-day mixed with the cut roots until the lambs are about five weeks old, and then until they are sold half a pound of bean meal should be added and mixed with the roots; this will not only make the milk richer for the lambs but will tend to make the ewes handle firm as well as fat, that being the state in which they will be most approved by the butcher. The course of feeding for the day will be hay in chaff first thing in the morning (after the lambs are fed), then roots and meal, the hay chaff being given twice a-day, the roots three times a-day. This plan involves trough-feeding entirely, and when roots are given it should be in such moderate quantity that it may be consumed entirely before the ewes leave the troughs. Between each time of feeding the troughs should be turned upside down to keep them dry, which is of consequence in meal-feeding. The old plan of giving cake and corn mixed with chaff is gone out of use by all the most intelligent farmers, because the ewes in seeking after the cake and beans used to rout the chaff out of the troughs and waste it. This is of more consequence than ever, seeing that the hay grown for ewe-feeding is composed of broad clover and yellow suckling without any rye grass as formerly; every particle of the hay ought therefore to be consumed, and so it will if given in moderation and between the intervals of root-feeding. By this method of feeding all the cake or corn given is in meal mixed with roots, and without waste, at the same time every sheep gets its share of the superior food as well as roots. It is also very much better for the health of the animals that in eating the roots the meal should enter the stomach at the same time, and this effectually prevents the scour or dysentery, to which sheep are particularly liable when they eat roots alone. Mangels are not generally used until the spring of the year—about March or April, but we have used them with great success, beginning with them in October and continuing through the whole winter upon the plan of mixing meal with cut roots; but this does not suit the lambs as above stated. To obviate this difficulty we always feed the lambs first; they then draw away from the ewes. In fact if they did not they could not get much in feeding with the ewes, because they eat all they are allowed before they quit the troughs. We have had some of the finest stock for exhibition and sale that we have ever seen by this plan of feeding with mangel. We have, however, had excellent stock on some occasions where our whole root crop has been carrots, and given with meal in the same manner. Under ordinary circumstances and the generality of seasons the ewes and lambs will be all sold and gone by the 1st of May; indeed, we have sometimes sold them all a little before that date. To enable us to do that all the lambs came in good time, and not later than the first week in February. We always prefer to sell the ewes which have suckled a lamb in their wool, as they do not usually show to the best advantage when shorn.

WORK ON THE HOME FARM.

Horse Labour.—One of the greatest improvements open to persons engaged in agriculture is the great saving which may be effected by employing fewer horses, for when powerful animals are kept and well fed attached to the most improved implements of light draught it is possible by rigid economy to reduce the cost of our horse labour to a very considerable extent. The generality of soils are now fast becoming ready for tillage, and the demands upon the horse labour of the farm are so pressing and so varied that it is difficult sometimes to decide which work shall be done first. Nevertheless, beans and peas and the culture for them seem first to demand the horse labour; next the planting of early potatoes; and where the land has been, as it always ought to be, autumn tilled, it is only a single horse plough that is requisite to forward the work. Rolling of grass land may be done in the event of the arable land being too moist for tillage; in fact, the clovers and all grasses intended for hay may now be rolled, and this work often requires more care than is usually taken. The

"Cambridge" ring roller is the best implement we think either for pasture or arable land, and when the latter is a stony soil it will require more than usual care at the time of rolling. Two horses abreast are to be preferred to two horses at length, because the roller is surer to cover the space traversed by the horses. We recommend that there should always be an odd horse upon the farm, and if the farm is extensive two may be employed with advantage, for it is not economy to break the pairs of horses in the usual tillage work to do the odd or casual jobs. The odd horse will be required at times to drive the fixed power for grinding corn, cutting chaff and roots for the cattle and dairy cows, also carting hay to the sheepfold, straw and sand for littering the pigsties, &c.; and where a milking dairy is kept a light active horse should be obtained and used for taking milk to the station for London or to a neighbouring town. A light active kind of horse for such purposes will be found exceedingly useful, and also for horse-hoeing roots, beans, peas, and all kinds of corn requiring it by using the implement with three adjustable hoes.

Hand Labour.—The men will now be employed in the field, assisting in sowing, drilling beans, peas, and planting potatoes. At other times they may be employed in any hedging, ditching, and banking work which may have been left in arrear. We have seen on some well-managed farms between the arable fields where no horned cattle are turned out, and where the hedges are not quickest, but composed of the general growth of woods, such as hazel, ash, maple, brambles, &c., that all the stubs have been cut close to the bank, so that all the grass which grows on the bank and borders may be cut for cattle. This was our own practice for many years, until we grubbed up all the internal banks and hedges. The produce being cut twice a-year, beginning the first week in May, affords capital food for dairy cows and young stock, and consisting of coarse grasses, cow parsley, hog weed, with other rough weeds, brambles, and young shoots of wood included, which being cut young afford food for cattle and pigs, breeding sows especially. If all is not eaten the remainder is trodden down for manure, and this is preferable to allowing it to grow and seed the land with weeds if it stood until after harvest. We know a dairy of twenty cows fed with the bank and border trimmings last year during the whole summer; each cow had 4 lbs. of cake per day, gave abundance of milk and paid uncommonly well, all the milk being sent to London, and the animals being kept in the house they made large quantities of manure. The women will still be employed in trimming and stacking roots before the sheep. At other times they will be stone-picking on the pastures and clover seeds. They will also be required in cutting potatoes in readiness for planting, and they will take part in the planting, for at this work they will do better than men, being more nimble and quicker in work. Where beans are planted after the dibble or dropped in the furrow they will take part in this kind of work with advantage.

THE PRESENT ASPECT OF POULTRY SHOWING.

No. 2.

WE endeavoured last week to point out what we consider unsound in the present system of poultry showing. The remedies for these evils are somewhat obvious. We will endeavour to give our ideas upon them as plainly and practically as possible:—

1. As to the multitude of shows and those often nearly at one date. Common sense would dictate without any suggestion of ours that there should be some previous consultation of secretaries, but somehow this does not seem to take place, to judge by the list of meetings from last August to October. The want seems to be some central medium of communication. We wish the Poultry Club now in process of formation would undertake the office and keep a register, to which secretaries might send word of the proposed days for their shows at the beginning of the year, and learn thence before the dates were absolutely fixed what other shows would be likely to interfere with their success. We hope the experience of last autumn will have done something towards making this unnecessary, and that some of those exhibitions which were heralded with so much parade and turned out perfect *fascos* will not be heard of in 1878. Not only, too, should shows not absolutely clash, but they should as far as possible be spread over the showing season, which we consider broadly from September 1st to February 1st. Many of the later shows—e.g., Manchester, Bristol, and Portsmouth, have fallen through, and we should, therefore, *a priori*, have expected that their times would have been taken by others, but not so. In spite of last season being a notoriously late one, at the shortest notice several committees, not content with their shows clashing, got them up at a very early period. Half-matured chickens figure at such, but seldom win again. Many of the greatest breeders do not rear early chickens, some from disliking the trouble of them in the cold months, others from knowing that they are seldom in the end the best specimens; others, as in our own case, live in a climate or position in which it is absolutely impossible to force chickens to early maturity, and consequently never have young birds in their full beauty and strength till the new year, when the present chicken shows are nearly or quite over. We would commend the catalogues of the Dorchester and Yeovil shows held last month

to the notice of those in doubt about a good time of year for theirs, where for modest prizes we find classes with twenty to thirty entries; while last autumn silver cups or pieces of plate were thrown away. It is true that Dorchester had before been known as a well-managed show; but Yeovil was a first attempt, and exhibitors could not have been certain that it would be, as we hear it was, admirably carried out. We certainly want one or two first-class shows late. It will be said, "The breeding season is too near at hand;" but all young birds are not required for early breeding, besides when fully matured they bear a show far better than at six or seven months old.

The financial question is a very serious one. The cases in which committees have tried absolutely to repudiate their liabilities are fortunately few; still there have been many cases in which prize money has been only forthcoming after much delay and pressure, and others in which exhibitors have received the embarrassing appeals to which we alluded last week. If the public, or fanciers in sufficient numbers to make it pay, will not come to a show, why should one be provided for them? "Oh," it will be said, "they are for the local fanciers;" but surely in these days local fanciers can see first-rate shows without travelling very far; if not they must pay for their amusement with substantial guarantee funds, and this in many places they do most handsomely.

What we would suggest is the holding of more local shows, or at least shows with many prizes for local exhibitors and fewer open shows. We are convinced from long observation that genuine fanciers are more encouraged by them, and the improvement of poultry more promoted by them than in any other way. Year by year at our own county show we are asked advice by several young fanciers who have won a prize or prizes with birds which, to say the least, would not be noticed at a large open show. These beginners are delighted at their success, buy something better, and in a year or two win in the best company. We could name a dozen who have thus started. Near Oxford, again, we have observed the immense growth of the fancy since the establishment of the Show there in 1872, and we believe this is greatly due to the local prizes in each class. Those who are thus interested in their poultry—viz., farmers, are the very people whom we should wish, if we are patriotic, to interest in it. The evil of "paying classes" has already been to a certain extent remedied by the public spirit of individuals and clubs who have at many shows guaranteed prize money. We thank them for it, and hope others will follow their good example. If, however, shows were better attended and managed by fanciers, not speculators, this would not be necessary, for the large classes would pay for the smaller. Again, where there is doubt about a good company coming, tack the show on to something else, or at least have it on the same day and near. It is true that the time of summer flower shows does not suit poultry well, but that of fruit and autumn flowers does so admirably, so does that of Christmas agricultural shows. Probably every visitor to the one goes to the other, and both are improved.

2. As to overshadowing, arising from the multiplication of shows, if the shows were reduced the evil would in a measure cure itself. We fear there is little chance of the class of exhibitors who buy birds for show just as a speculation giving up their cruel amusement for any words of ours. There are many others, however, generally beginners, who, with the best intentions, through what we have called an excess of enthusiasm for the fancy, and in perfect ignorance that they are hurting their birds, do overshadow them. To these we would say a word. Shows are an unnatural and exciting atmosphere for birds, and, unless great judgment is used, must after a time impair their constitution. Young fanciers see the name of some great breeder again and again at all the great shows, and do not reflect that his or her birds are probably legion, and that different representatives appear at different places. We have exhibited much ourselves, but as a rule make six shows in the year the very utmost to which we send any one bird of the larger kind; some of the smaller birds will with impunity bear more. No hard-and-fast line can be drawn, for the length of shows is so various; a summer show of six or eight hours under canvas does no harm to birds. It makes much difference, too, if an attendant be sent with them to bring them in just before the judge goes round, and take them straight away at the close of the show instead of their being tossed about on railways for twenty-four hours or more. With this moderate amount of exhibition birds will live and breed for many years. We lost last autumn a Dorking hen, which is not generally considered a long-lived breed, to a day eight years and a half old. She had won thirty-three cups or prizes, and laid fertile eggs within a few weeks of her death; but though shown in 1869 and 1877, and many times in all the intervening years, she had never been overshadowed, and never at all till fully matured. We simply mention this fact to show what care will do.—C.

VARIETIES.

MR. ODAM in an excellent pamphlet on the cattle traffic and cattle diseases, concludes that "it will be useless to attempt stamping out contagious cattle diseases so long as those diseases

are admitted from abroad; and that when foreign animals are totally prohibited the farmers will be ready and willing to submit to any necessary restrictions and regulations under the direction of the central authority, but that until then any material interference with home traffic would be premature and useless. The matter rests with the public. Producers have much at stake, and their interests are happily identical with those of the public, whilst the dividers are against both. Consumers will have to decide on the course of action to be taken, and they may depend that the first step towards obtaining cheaper meat must be in the direction of shutting out and keeping out foreign contagious diseases of animals." It is on these principles that the Government Bill on this important question that was introduced into the House of Lords on Tuesday evening last is founded.

A RECENT paper by a German scientist contains the following, relative to a proper selection of eggs for setting. To get good strong birds, eggs from a two-year-old hen by a one-year-old male bird should be chosen, as these yield far larger chickens than eggs from a very young hen by an older male. The eggs should be regular in shape, and the largest should be chosen, except, of course, when a double yolk is suspected. In dwarf breeds, where the object is to get as small birds as possible, the smaller the eggs the better. The notion that pointed eggs always yield male birds is incorrect; this is only the case when they are from a hen that usually lays round eggs, while similarly round eggs from a hen that usually lays pointed ones generally yield female birds. Where, however, a hen always lays eggs of one shape, whether pointed or round, the young birds will be of both sexes.

It is in contemplation to hold an exhibition of poultry and pigeons in the Drill Hall, Hemel Hempstead, on Thursday and Friday, September 26th and 27th, the latter day being the date of the annual show held in the Corn Exchange by the Floral Horticultural and Cottage Garden Society. Mr. O. E. Cresswell and Mr. Leno are announced as judges, and Mr. Stallon is the Hon. Secretary.

REFERRING to the properties of cotton cake for feeding, Dr. Voelcker has stated that undecorticated cotton cake should not be given to calves, and decorticated cotton cake required to be given to animals judiciously. He had had brought under his notice more than one hundred cases in which cotton cake was alleged to have poisoned sheep and cattle. He found, however, that the alleged injury was due to the injudicious way in which cotton cake was given to stock. A food so rich in albuminous compounds as decorticated cotton cake required to be broken up very fine, or better still, to be ground into meal, which should be mixed with twice its weight of Indian corn, rice meal, or other meals comparatively speaking poor in nitrogenous or albuminous compounds, and rich in non-nitrogenous or starchy constituents.

THE *Zeitung* communicates a plan of testing milk, which possesses the merit at least of simplicity. A well-polished knitting needle is dipped into a deep vessel of milk and immediately withdrawn in an upright position, when, if the sample be pure, some of the fluid will be found to adhere to it, while such is not the case if water has been added to the milk, even in the smallest proportions.

THE plan of breeding the stock kept upon the farm rather than going into the open market for fresh faces, has, says the *Agricultural Gazette*, so many advantages that we wonder it is not more generally practised. There certainly are men who are peculiarly suited for the delicate and difficult task of buying stock. With expert eye they pick out the lots most suitable for their requirements, and by skilful manipulation, if we may so speak, they succeed in buying them cheap. Such men delight in marketing, and, as everyone has a strong point as well as a weak one, it may be the wisest course for them to continue to buy and sell and get gain. With others marketing is about the most distasteful part of their business. They delight more in the work of superintending the cultivation of their crops and the rearing of stock, while market banter and market cheek they would gladly dispense with. Breeding their own stock cannot fail to be attractive to such persons. We think there are three good reasons for persevering in breeding rather than in buying stock: First, the pleasurable occupation of improving a home stock; secondly, freedom from disease; and thirdly, as we believe, a larger profit during a course of years.

A GERMAN farmer and student, who kept cows on a great variety of dietaries, found that most milk was produced by a mixture of 5½ lbs. of rape cake, 25 lbs. of oat-straw, and 36 lbs. of mangels. He found that 1 lb. of rape cake produced 1½ lb. of milk. From his experiments it would appear that it is not possible to produce milk specially rich in butter or in cheese, or, in fact, in any one ingredient; but it is certain that abundance of good food, especially if rich in fats, produces milk rich in all its constituents.

THE experiments of Voelcker show that farmyard manure does not lose very much by exposure to air, and light. The deterioration which ill-managed manure heaps undergo is principally due to losses by drainage. The dark-coloured liquid which is often seen flowing away from badly-kept dung heaps is rich in

nitrogen, phosphoric acid, and potash. It has been found through careful experiment that 100 loads of dung kept in the usual wasteful manner were reduced at the end of 81 days to 73.3 loads, at the end of 285 days to 64.4 loads, 884 days to 62.5 loads, while at the end of 499 days the original 100 loads were reduced to 47.2 loads, sustaining a loss of 52.8 loads. Thus in sixteen months more than one-half, and that the most valuable portion, of the manure had disappeared, leaving a highly carbonaceous matter poor in all the elements of fertility.

— ANSWERING the question of which kind of fowls to keep, the *Prairie Farmer* says:—If you want eggs through the greater portion of the year, but do not care for poultry for the table, keep the Leghorns. If you want eggs through the winter at the time when hardly any other varieties are laying, keep the Light Brahmas or White Cochins; in fact, to those who want a beautiful breed of fowls for fancy stock we unhesitatingly recommend the White Cochin. We know of but few varieties that show as well on the lawn or in the poultry-yard as this breed, and as good winter layers they are very favourably known. They are very quiet stay-at-home birds, and quite a low fence will keep them. The young Cochins, say at from eight to ten weeks old, makes a capital broiler, being round and full-breasted; but for roasters, however, the Cochins is of little value until it has matured, and even then it cannot compare with the Brahma and some other breeds. As mothers for early chickens White Cochins are unexcelled; they are large, and being covered with a heavy coat of long fluffy feathers they can cover quite a numerous brood.

WINTERING BEES.

I HAVE often recommended bee-keepers to keep their hives well covered during the winter and spring months, for I invariably find that hives warmly covered keep their bees better in winter and do better in spring than those not so well covered. The longer I live and the more experience I gain the more disposed am I to emphasise that statement, the "RENFREWSHIRE BEE-KEEPER'S" expressed contrary opinion notwithstanding. He says, "If cold is so prejudicial to bees, how comes it that power is given them to resist the intense frosts of the fearful winters of Russia and North America with impunity?" Is not this a mere assumption? Do bees bear those winters with impunity? If they do where shall we find the evidence? I have read American books on bees, which tell us that the preservation of bees in winter is a great difficulty in America. Large bee-keepers there build houses with thick walls and without windows in which to winter their bees. I advise our Renfrewshire friend to read "The Mysteries of Bee-keeping," by Moses Quinby, a work of great merit by a writer of very great experience. In one of these thick-walled houses Mr. Quinby wintered his hives, and he kept hundreds of them. The "RENFREWSHIRE BEE-KEEPER" says that "eighteen years ago on the memorable morning of the 24th of December, 1860, the mercury in the tube of a thermometer inside a hive shrank to 7°, or 25° below the freezing point, and yet that hive survived and came through in fine order." I well remember that night and that frost, which kept me at my hothouse fires all night and killed to the ground all laurels, aucubas of the neighbourhood, and many hollies and other kinds of plants. Moreover, that frost killed more than three-fourths of the bees and hives in the north of England. That frost doomed thousands of hives to extinction. The country was nearly swept clean out of living bees by the cold of that night. Our friend was very fortunate in having his hive preserved alive, and this he ascribes "to the thorough ventilation afforded by slides of Indian matting running in its bar groves at the top."

One more quotation from the letter of the "RENFREWSHIRE BEE-KEEPER" and then I shall finish. He says, "Having served my apprenticeship to bee-keeping amongst the colonies which were long located in our house roof here, it was long a puzzle why such vagabond swarms preferred settling with us as well as in neighbours' roofs at the very coldest or north aspect, till at last the truth forced itself upon me that it was there they enjoyed the most thorough and undisturbed dormancy with the consequent minimum consumption of honey." It appears to me that what our friend calls a "truth" is nothing more than a mere fancy. That the swarms he mentions went to the north ends of the houses he saw I doubt not. Twenty instances of swarms going to the north ends of houses would not prove that bees prefer cold to warm situations. Cavities with old combs in them either at the north and south sides of roofs of houses will attract swarms; and hives with combs but without bees standing under a burning sun are as attractive to swarms as those standing in shady places. The idea of bees seeking a cold corner and quiet dormancy with consequent minimum consumption of food is, to say the least, a very novel one.

The idea of dormancy is not new, neither is the fact that bees eat less in cold winters than they do in mild winters; but I think the question of best climate for bees in winter is still unsettled. The death rate of human beings is generally greatest in cold weather, and in my experience the death rate of bees is very much greater in cold than in mild winters. I have noticed that after

mild winters, during which the hum of comfort has been heard in hives, the bees were healthy and numerous in spring. If bees venture out of their hives when the mercury is below 60° many are chilled to death, and if they fall into snow they become motionless and collapse immediately. I hold that a warm corner out of doors is better than a cold one for bees in winter for many reasons, and that hives cannot be too well protected from cold and storms.—A. PETTIGREW.

OUR LETTER BOX.

BRAHMA COCKEREL (J. A. B.).—Your question is a vexed one, but we will give our own experience. The cock hatched in May, now nine months old, should be tolerably developed. In point of growth he should have attained his maximum. He, however, requires to furnish and to put on weight. Two things are to be avoided. The first is to cause him to lead a solitary life, the other to give him too much society. We advise you to give him two female companions and to feed well. From your description he will never be a very large bird; but size is not the only merit of a Brahma.

EGGS IMPORTED (An Irish Subscriber).—We cannot tell the number, but the value of those imported from France in the first half of last year was £1,434,885. The price varies too much to state an average. A poultry company has been tried and failed; epidemic disease could not be kept away. For profit we should keep Dorking hens and a Brahma cock. The other queries cannot be answered. The experiment would not be costly to try.

BAR-FRAME HIVE (Cabinet Maker).—You will find drawings in our Manual "Bee-keeping."

REMARKS.

6th.—Dark dull morning; finer afternoon; dry but dull night.
7th.—Fine sunny morning; rather foggy in afternoon. Moon and Venus very bright about 6 P.M.; slight fog in evening.
8th.—Thick white frost in early morning and fog; little sunshine in middle of day; very foggy in afternoon.
9th.—Slight rain in morning; dull cloudy day, but a little brighter in afternoon.
10th.—Thick very damp fog all day, and at times quite dark; fog cleared at 9 P.M.; slight rain.
11th.—Cloudy but dry day, without fog from night.
12th.—Bright sunny day; lunar halo 6.10 P.M.; fine evening, but heavy rain after 9 P.M.
A cold week, with high barometer, very little wind or rain, but a great deal of damp fog.—G. J. SYMONS.

COVENT GARDEN MARKET.—FEBRUARY 13.

GOOD late Grapes are now beginning to fall off very much, most samples showing signs of a finish. The first Strawberries this season were on show last week, but though poor fetched a fancy price. Forced and outdoor vegetables are in good supply, prices ruling below the average.

From observations taken near London during forty-three years, the average day temperature of the week is 52.8°; and its night temperature 32.6°.

KITCHEN GARDEN CROPPING.

HE season has again arrived for the arrangements to be made, if not already done, for cropping the kitchen garden, and I would advise that all be arranged on paper, that nothing be left to memory or chance.

Crops which remain on the ground a similar time should be placed as much as possible together, rather than putting all Broccoli or all Potatoes together, whatever their season of becoming fit for use. Large quarters can be worked more economically than small plots, and small strips becoming bare between standing crops betray a want of system and forethought. Broccoli which turns-in in December and January should not be mixed up with such sorts as are only fit for use in April and May; the former will be off in time for early Peas, to be again followed by an autumn crop of Cauliflowers, Broccoli, or salading, while the latter may be succeeded by Celery or late Peas. Early Potatoes, such as Ashleaf or Myatt's Prolific, will be off in June and July in time for Carrots, Turnips, Borecole, and a host of other crops, including Winter Spinach; while late Potatoes will only be off in time for Cabbages. We ought always to have two or three successive crops in mind when making arrangements for planting one.

More than half the kitchen garden is capable of being cropped twice in a year, and there are some winter crops which never seem to be too abundant; while there is invariably a large breadth of ground in most gardens bare in late autumn and winter which, if proper forethought had been used in spring when arranging for the first crop, might have easily borne a second, and in some cases a third.

A garden often has peculiarities which seem to point out certain crops for certain places. Every natural advantage should of course be turned to account. If one part is light, dry, and warm, we should not by preference plant Celery in that particular spot, nor Potatoes where it is comparatively wet and heavy. Then, again, Celery takes a large quantity of manure, necessitating much wheeling; therefore we try to make the distance as short as possible. Onions like a heavy soil, but they also like sufficient heat to ripen them not later than the end of August. Peas, Cauliflowers, and Lettuces can scarcely have the ground too rich in manure; but Broccoli if grown too luxuriantly will not endure the frost. Savoy and early winter Broccoli, such as Snow's or Veitch's Protecting, may very well be neighbours, as they would occupy the ground about the same time; the same may be said of late Broccoli, Winter Spinach, and Borecole. I have these three together now, and they will be followed by Celery, with Lettuces, Turnips, or Cauliflowers between the trenches. Brussels Sprouts were planted between Potatoes thus: The rows of Potatoes were a yard apart, were earthed-up before they had scarcely appeared above ground, and the Sprouts were planted in the furrows. Peas, excepting the earliest, are 9 feet apart from row to row, and have two rows of Cauliflowers or Spinach between. A portion of these will be off in time to be followed by Endive and late Lettuces. Another

instance of double cropping which we sometimes practise with advantage is to plant alternate rows of late Broccoli and Cauliflowers 2 feet apart. When the Cauliflowers come off the Broccoli is left 4 feet from row to row, which admits plenty of air to harden it and plenty of room to walk between when it is wet in winter and spring. There is no waste of ground in this method, because space is always plentiful in winter, and if it is likely to be wanted before the Broccoli turns in the crop can be taken up and laid-in elsewhere at almost any time.

Two wet winters and a cold wet summer have not been quite the sort of seasons we should have wished for our heavy soil; they have left traces which will not be entirely obliterated this year if the weather is ever so favourable. It is all very well to say, Keep off the ground when it is wet, and to make resolutions to that effect; but crops must be gathered wet or dry, for monsieur the cook will not wait for fine weather or dry soil. Many of our Potatoes last July were dug when it was wet overhead as well as under foot. We use on the average nearly a bushel a-day, and last summer we had to dig a long way for a bushel. It is to be hoped we shall not have such another unfortunate season for a long time. We are using a good deal of burnt clay and lime this spring, and very little manure at present. By these means, with the aid of the fine drying weather we are now enjoying, an improvement may be confidently expected.—WILLIAM TAYLOR.

CULTURE OF MIGNONETTE IN POTS.

GIVEN sufficient space under glass a good gardener should have a supply of Mignonette in pots throughout the year. That this is desirable there can be no question, and I am inclined to think it is practicable in many more gardens where it is not attempted, it being really surprising in how few places we meet with good practice in the culture of this simple but charming old favourite. But there are exceptions—striking exceptions, and one such very recently came under my notice.

I happened about a week ago to be at Searles, the seat of Sir Spencer Wilson, and in looking through the compact and admirably finished little glass houses with Mr. Barnes I came upon about a dozen splendid specimens of Mignonette, any one of which would measure upwards of 2 feet in height and as much in diameter—thick dense bushes abounding with stout vigorous branches clothed to the centre with large, green, healthy foliage, full of growth, for they had no expanded flowers, hardly a visible flower bud, and with such an abundance of on-coming shoots for tying-out that they might if required be brought to specimens of the largest size in a brief space of time, or be made to burst into flower in their present very satisfactory stage of existence. "Why!" said I, "one of these plants in full bloom would fill a room with its perfume, and unless the room was a large one two plants would be almost overpowering." "Yes," said Mr. Barnes, "they are very sweet. We have some in flower in the conservatories now, and they are much liked." Of course I wanted to know all about them, for the chance to gain a lesson was too good to be

missed, and yet there was really very little to tell. The seed was sown last May; the plants, kept entirely under glass, were not suffered to become rootbound, but as the roots reached the sides of the pots larger pots were given, the soil used being a rich gritty loam, and when the plants were finally placed in the large pots in which I saw them the lower half of the pot was filled with manure placed upon the drainage and rammed into a firm compact mass, upon which the plant was placed and the upper portion of the pot filled with loam, so that each pot contained a mass of rich manure into which the plants had rooted, hence the robust growth and rude health.

Let me not, however, ignore the skilful training and painstaking care which had so evidently supplemented a clear and distinct knowledge of the food requirements of the plants. For some six months had they been tended—pinched, trained, and watered regularly; all simple matters, but all indispensable to success.

Does the term "rich gritty loam" puzzle anyone? If so, I may explain that soil from a meadow where the grass is good, or ordinary garden soil enriched with old hotbed manure, a little soot, and containing enough silver sand to afford a free quick passage to water, is what is meant. Liquid manure probably plays an important part here as the flower buds are forming and during their expansion. This I did not ascertain, but as then the richer constituents of the solid manure would be pretty well exhausted by the greedy roots, a rather frequent dose of clear liquid manure is calculated to be of material service and could certainly do no harm.—EDWARD LUCKHURST.

STEAMING, DAMPING, AND SYRINGING VINES— DUKE OF BUCCLEUCH GRAPE.

I WOULD not have desired to offer any further remarks on my success in growing the Duke of Buccleuch Grape, nor have referred to your able correspondent Mr. Douglas's failure in growing this splendid Grape. were it not to reply to his question as to my being prepared to reiterate my statement regarding good Grape-growers having discontinued "steaming, damping, and syringing" their Vines, and whether I produced any moisture at all in my vineries from evaporation. Mr. Douglas says that I said that I do not; but if he will look at my remarks again he will find, if words have any meaning at all, that I did not say anything of the sort. What I did say is that "the Duke of Buccleuch will not succeed under a system of steaming, damping, and syringing, now abandoned by all growers of good Black Hamburgs," but I did not say that I did not produce any moisture from evaporation in my vineries. Mr. Douglas states that the old system had been abandoned for the new one of no atmospheric moisture at all.

Your correspondent is no doubt well aware that there are extremes in almost everything, but I courteously object to being made to say that good Grape-growers aim at an atmosphere without moisture, and would remind him that if they did they would most assuredly fail. "Steaming, damping, and syringing" is the one extreme, and an atmosphere "without moisture at all" is the other, and both are no doubt inimical to the growth of good Grapes; but in the case of Vines otherwise well managed I would much rather approach the dry than the vaporising extreme point. The fact is, this atmospheric moisture is one of the most important points in Vine culture; and from a very much longer practice than Mr. Douglas, and a wide range of observation, I have come to the conclusion that there is far more evil to be attributed to the damp than to the dry extreme in the vineries of this country. However strange it may seem to Mr. Douglas, I am not acquainted with any really first-class Grape-grower who at this era of horticulture steams hot pipes, damps floors, and syringes his Vines. Mr. Douglas must mark my combination of circumstances, and remember that such was once a very much more common practice than it is now, and one which I have no hesitation in saying is not in harmony with the soundest Vine culture.

I am at no loss to understand why Mr. Douglas fails in growing good Duke of Buccleuch Grapes if he steams, damps, and syringes them; but I must confess that I am at a loss to understand how he brings out to our shows those clean Black Hamburgs if he follows this vaporising system. He is not so old nor so extensive a grower as I am, or he would remember how in my young days this steaming, damping, and syringing system combined was practised, and under which treatment I must reiterate I have never seen clean, well-finished, highly flavoured Grapes produced.

As I said before, I grow good Black Hamburgs and Duke of Buccleuch side by side in the same vinery, and, as one of the Editors of this Journal knows, they would not disgrace such a house of generally high culture as Loxford Hall. Mr. Douglas reiterates his inability to grow good samples of this Grape, and I am sorry for it, for it is, as he remarks, a noble Grape. It does seem strange that what some succeed in, others, such as Mr. Douglas, who ought to be expected to succeed also, fail in growing it well.

I will encroach on your space in giving what may be a clue to success in growing so desirable a Grape. This moisture, evaporation from steaming, and syringing has, I fear, in many cases something to do with it. I do not mean at its finishing stage only, but throughout its whole course of treatment. I give it no special treatment, but year by year over a long experience and extensive practice I have produced less and less moisture in the air of vineries by even sprinkling the surface of borders, not to say anything of steaming and syringing. I believe the latter to be a practice that will one day be obsolete, for I regard it as one that cannot be justified either by natural philosophy or vegetable physiology. Moreover, I believe the virtue of keeping down red spider attributed to the system to be a delusion, and that it creates a texture of leaf that invites that insect. Perhaps it is a system that first arose from the high night temperatures that were practised, and the two evils combined are incalculable in the case of Grapes grown under such artificial circumstances. In my own experience I find I can produce cleaner, better finished, and better flavoured Grapes, and finer wood and foliage, with a minimum of this vaporising system; and as to syringing, I rarely ever wet a leaf. The chief evaporation from artificial means that takes place in my vineries arises from occasional heavy waterings to inside borders; and even in that case I give more liberal ventilation to let the moisture quickly out for a few days, and there is nothing I dislike so much in a vinery as steam.

I practise low night temperatures, and like to see the pearly dewdrops on the edges of the Vine leaves at daybreak; and I venture to say that anyone who practises low night temperatures and a minimum of evaporation and syringing will never return to what I consider overheated pipes and water-spilling to counteract their bad effects. In this practice I have often wondered how it was possible to have ignored the teachings of Nature and the laws upon which a sound healthy growth is dependant. The result of this low night temperature and so little vaporising is very striking in the fine stout shoots, and thick dark green leathery leaves, and absence of red spider. Never in my earlier practice could I produce leaves of such colour and substance when the steaming and syringing was so common. Provided the Vines are in a good border and properly supplied with moisture at the root, I should like to ask Mr. Douglas if the atmosphere in this country is ever in a state of "no atmospheric moisture at all," or in one so much approaching to it as to injure the foliage or fruit of the Vine.

High night temperatures, a maximum of atmospheric moisture, and loose spongy rich borders I have come to regard as three of the greatest evils in Grape-growing. If lower night temperatures, less moisture by evaporation, and if borders were put together in a drier state and rolled or even rammed, and the animal manures were laid on their surfaces instead of being incorporated with the soil, all the other conditions of good Grape-growing are very simple indeed; and I cannot but think that the failures in producing really fine Duke of Buccleuch arises from some cause in itself not sufficient to mar Grapes of a hardier constitution, but which at the same time would be better absent.

Not being able to reply to Mr. Douglas's question as to the position of the Duke at Tweed Vineyard, I, on receiving your Journal took the liberty of writing and asking Mr. Thomson to what extent the Duke had a footing in his vineyard, and to-day I have his reply with his sanction to make any use of it I choose. Mr. Thomson writes: "I fruited the Duke for five years before it was offered to the public. In 1872 635 lbs. of it were sent to Covent Garden, and made exactly double the price of Black Hamburgs grown in the same house. I sent fruit of it that season to the Fruit Committee, with the request that before an award was made they should send a competent person to inspect and report on the crop of it here in all its aspects; and, as is well known, Mr. Barron made a careful inspection of it, and from his report it was awarded a first-class certificate. As far as I am concerned I do not

know of any other person who took such special precaution that the qualities of a seedling Grape should be justly estimated. We fruit heavily every year the seventy-one rods that Mr. Barron inspected, and intend, now that we are doing away with Pines, to extend it. We do not send so much of it to Covent Garden, the berry being large and the skin rather tender it suffers from the long journey; but our chief reason for not sending is the rapid home sale we have for it. One titled lady who buys her supply of Grapes from us stipulates for the Duke only, and requests that we keep a supply for her as long as possible. In 1876 we planted a number of Vines of it, and each Vine bore eight bunches last year, some of which took a first prize at Carlisle. These Grapes showed neither crack nor spot, and I may remark that the circumstances under which it is grown here are of the most ordinary kind. Had I been ever so anxious to retain the Vine in my own possession it would not have been easily done, for before it was sent out I had requests for eyes and Vines of it from all who saw it in crop here. I regret that good Grape-growers like Mr. Douglas fail to grow it well; but I remember the condemnation Lady Downe's met with and the position that Grape holds now, and I hope the same fate may ultimately be the Duke's."

The Duke will find its proper level some day like most men and things. In the meantime perhaps Mr. Douglas and others have a good right to condemn it from their own experience. At the same time I must regard it as a first-rate Grape, seeing that I cannot send any other Grape to my employer's table that has such a grand appearance, nor any that is more or even so much appreciated, and perhaps my foregoing remarks may help to show him how it is cultivated; if so they will be worth a place in your excellent Journal.—COLUMBUS.

VEGETABLE CULTURE.

CHAP. VIII.—THE CARROT.

THE Carrot is found growing wild in many parts of Britain. In some gardens it grows freely without much trouble, and in others it is very difficult to cultivate satisfactorily. With a little care, however, it can always be grown very fairly, and it amply repays any extra attention bestowed on it, as it is quite indispensable in the kitchen, and nothing else can be grown as a substitute.

We always sow our Carrot seed for the first drawings early in January, and from then on until the middle of February. The earliest sowing is made in a two-light frame on a dung bed. Leaves, stable manure, or anything that will ferment, is thrown into a heap and allowed to lie for a week before packing it up in a bed about a foot wider on all sides than the frame which has to be placed on it. When the bed is made up the frame is set on the top of it, and then about a foot of soil is placed all over the inside of the frame. This soil should always be of a light open nature, and when there is the slightest suspicion of worms or maggots of any kind being in it a quantity of fresh soot or lime should be mixed up with it. A spadeful of either of these ingredients to every barrowload of soil effectually prevents vermin depredations. As soon as the soil has been spread on the bed the seed may be sown. In frames we always sow it broadcast, as more produce can be had from a small space in this way than by sowing in rows. About half an inch of soil should be sprinkled over the seed. Early Horn or French Horn are the only sorts which should be grown in a frame. Either of these varieties sown the first week in January on a hotbed from 1 foot to 18 inches in thickness produce roots for use in May.

When the weather is favourable the first sowing of Carrots may be made in the open ground in the first or second week of February. At this time they should be sown on the early vegetable quarter, which is a south border, or the next warmest and most sheltered place to it. The two varieties named are those only that should be sown now, and as their roots do not descend more than 8 or 10 inches it is not necessary that the soil be more than 1 foot or 15 inches in depth. Of course if it is deeper than this it will do no harm, but at the same time a shallow soil need not be avoided. An open soil is, however, of great importance. Carrots will always succeed, so far as the openness of the soil is concerned, in ground from which Potatoes have turned out well and clean during the summer previous. We always have winter Turnips, Spinach, or something of that kind on our early Carrot ground, or it would be turned over and left rough in autumn; but as it is, it is only dug over a week or two before the seed is sown, and yet the result is very satisfactory. As prevention is always better

than cure, whenever the ground is dug for Carrots a quantity of soot and lime should be turned into the soil. This is a much safer plan than trusting to kill the maggot with some kind of liquid after the plants are up.

The surface of the ground should be broken fine with the fork just before the seed is sown. Drills 10 inches apart and 1½ inch deep should then be drawn, the seed sown thinly, and covered with fine soil. As soon as the plants are up sufficiently to show the rows the Dutch hoe should be run between them when the soil is dry. When the plants come up in crowds they must be thinned-out to 12 inches apart as soon as they are 3 inches high. By the time they again become crowded the roots will be forming, and every other one may be pulled out and used. It is very seldom that these short Carrots are stored for winter use, and they are best pulled out of the ground as required and used in the early part of the season.

For the main crop, which consists of long-rooting kinds, a deep soil is necessary; 2 feet is not too deep, and it should have been trenched to this depth either a year before or just before the crop has to be put in. When the soil chances to be heavy a liberal quantity of ashes and leaf soil should be worked into it besides the lime and soot. Rough manure, which will prevent the roots from penetrating straight and cause them to be forked, must not be added to the soil; and when Carrots are to be grown on a piece of ground which was heavily manured the year previous, better shaped roots will be secured if no manure is added when digging the ground for the Carrot crop. For the main crop in shallow soils James' Scarlet Intermediate is the best, and in deep soils Altringham and Long Red Surrey have no equals. About the middle of April is the best time to sow these. The rows should not be less than 1 foot apart. As the seed often adheres together it can be distributed much more evenly in the rows when it is rubbed between the hands and mixed with its own bulk of dry sand before sowing. As soon as the rows are visible the Dutch hoe must be run between them. When the plants are large enough to handle they should be thinned out to 3 inches apart. Run the hoe through them again after this. When the leaves again begin to meet every other plant must be drawn out, which will leave them 6 inches apart, a distance at which good roots and a profitable crop can be grown. After this thinning, and at intervals of about three weeks during all the time they are growing, they should be deeply hoed between the rows to keep the surface open and free from weeds. Their cultivation when sown broadcast in beds does not differ in any important particular from the mode of growing them in rows. They must be thinned the same, and a small hoe run amongst them occasionally. If the precaution has not been taken to make the soil obnoxious to grubs by digging in some of the above-mentioned materials for this purpose, when they do begin to eat the roots, which is easily known by the leaves turning yellow, these depredations are often stopped by watering the rows with lime water; soot water is also very good when used strong.

The roots need not be taken up until there is danger of frost injuring them. This may be in the early part or towards the end of October. They should not be lifted until after a few days of dry weather. The leaves should be cut close off to the crown, and the rough of the soil rubbed off with the hand as they are taken up. They should then be laid in an open shed for a few days to dry thoroughly before storing. When properly stored they will keep in good condition all through the winter and until the young spring Carrots are ready for use. The best way of storing them is to pack layer after layer of them in dry sand and in a cool dry shed. They should be turned over whenever there is any suspicion of any decaying. Where ground can be spared a patch of Short Horns sown in a sheltered position about the end of July gives a supply of sweet little roots late in autumn, but when a good main crop is grown the want of these is never felt.—A KITCHEN GARDENER.

CHRYSANTHEMUMS AND ZONAL PELARGONIUMS IN WINTER.

IN the Journal for January 24th is a note describing the system I adopt to obtain Chrysanthemum flowers in quantities through January. I have sent you a few blooms to show that these are still to be had, though now in diminished numbers. In the same note just referred to, the great value of Zonal Pelargoniums during the winter months is alluded to. I grow these almost entirely for winter work; and the easiest mode of

growing the plants, the results being as good as from more laborious modes, is to plant out young plants in summer, prepare them for lifting by raising each plant sufficiently to break off most of the roots, and a fortnight afterwards lift them entirely and pot them into the smallest pots possible. Place them in a cool position for another week or two, and then house them. The old plants after supplying cuttings are draughted into mixed borders.—R. P. BROTHERSTON, *Tynninghame*.

[The specimens were very good.—Eds.]

JUDGING ROSES.

WITH the exception of one point I do not think there is much difference of opinion between "WYLD SAVAGE" and myself. We both repudiate the complex methods offered for our acceptance, and I fancy we both disclaim the notion that a good judge need to be taught how he is to adjudicate. The one point on which we differ is on the value to be attached to Tea Roses in a stand, "WYLD SAVAGE" maintaining that their presence of itself constitutes a point in favour of a stand compared with those where they are not. I am, as he is, a great lover of the Tea Rose, and I am sure I shall disarm somewhat of his criticism when I tell him that the Editors of the *Journal of Horticulture* having placed at my disposal the sum of three guineas to be competed for at the National, I have allocated it to a class which has never yet been shown—eighteen Teas and Noisettes, six varieties, three blooms of each, and if I mistake not it will bring out some beautiful stands; so if I differ from him it is not that I undervalue this very beautiful and chaste class of Rose.

Well, the same Journal in which his last note appears gives evidence that there are some people who have that chronic cold in the head about which he writes. When he names *Maréchal Niel* and *Cloth of Gold* he names two Roses that are not Teas but Noisettes, and Roses which have such an exceptional position that they are hardly to be taken into account. Leaving them on one side, what do we find in the election of Roses?—that Hybrid Perpetuals head the list; and that while *Marie Baumann* receives forty-six votes *Catherine Mermet*, the highest of the Teas, receives only thirty-five; and that while "WYLD SAVAGE" places six Teas and Noisettes as the highest in order of merit in his list, not another elector places one in the first six save *Maréchal Niel*. Now let us suppose two stands of twelve in which the Roses are the best of their sort that can be shown, one to comprise the twelve highest in the list—*i.e.*, *Marie Baumann*, *Alfred Colomb*, *Charles Lefebvre*, *Maréchal Niel*, *Baronne de Rothschild*, *François Michelon*, *Louis Van Houtte*, *Etienne Levet*, *Marquise de Castellane*, *Madame Victor Verdier*, and *Duke of Edinburgh*; and the other to contain, according to "WYLD SAVAGE's" list, *Maréchal Niel*, *Souvenir d'Elise*, *Souvenir d'un Ami*, *Marie Van Houtte*, *Catherine Mermet*, and any seven in the first stand. I contend that in judging the adjudicators ought to decide on the merits of the Roses, and not score a point for No. 2 because it contains five Teas and the other only one; and I say also that the great body of electors who placed their Roses in order of merit bear me out in this.

I may, without betraying secrets, say that this subject was discussed at the adjourned meeting of the Executive Committee of the National Rose Society the other day, and that one of its members who is thoroughly competent to do it undertook to collect opinions on the whole subject of judging, and has kindly promised to prepare a paper for the Society.—D., *Deal*.

I ENTIRELY endorse "WYLD SAVAGE's" main position. I protest against the complicated systems of card-placing and minute giving of marks as impracticable at any large show, and likely to lead to endless disputes. When I have myself judged, the system which he describes has always been the one followed, and, in going over boxes afterwards with nurserymen and their foremen, it has been the method invariably pursued if we wished to criticise the judging. It is unfair to criticise the judging unless it be done early; blooms alter so much.

Mr. Camm differs in no essential from Canon Hole, who defines at page 207 ("Book About Roses," ed. 2) what a show Rose is, and at page 259 what a Rose judge should be; and I firmly believe that almost all practical exhibitors are agreed about it. The precise order in which the points of merit stand is not in my mind very essential. If a Rose lacks utterly any main point it is a bad bloom, whether it be an ugly shape, dirty colour, or puny size. I do not believe that any proposal to allow for the distance that blooms have been brought would

be entertained for a moment. The only question is what they are now. The really important need is to have competent judges, and it is here that country secretaries often fail from want of knowledge of the special subject. I have never had a word to say against the verdict passed on my blooms at a London show, but elsewhere it has not always been so. Twice last year I suffered in this way, my estimate being confirmed by a first-class nurseryman. Secretaries of country shows do not always understand that only a successful exhibitor at first-class shows can really judge. I believe that no man can be a competent judge who is not constantly engaged with a large collection of Roses, and is also a successful exhibitor. Matters are not indeed so bad as in the days when judges were appointed because they had once taken a prize for Cucumbers, or because the mayor knew their uncles, but they are still sometimes appointed because they are clever gardeners, or for some other insufficient reason. An exhibitor should make sure that he is a better rosarian than the judges before he controverts their verdict. I have often silenced a discontented exhibitor by the remark, "Do you know who judged them?"—T. H. GOULD, *Mortimer*.

I AM neither a Tea man nor a Perpetualist. I am not sure that I am a rosarian, but I have been a lover of Roses for thirty years and a grower of them for more than twenty years. I have attended some of the best metropolitan Rose shows, and have judged at a few metropolitan exhibitions. I have observed much perplexity on the part of judges and discontent on the part of exhibitors. So it must ever be when men have to lay down the law without any law to guide them. Exhibitors as a body cannot be satisfied so long as judgment depends on the mere fancy of an individual. Unless the National Rose Society frames rules of guidance, clear and explicit, for the judging of Roses, I do not think it can be "looked up to" higher than any other Rose society.

I regard Roses as Roses—not as Teas or Perpetuals. I cannot see why a Tea Rose, because it is a Tea, should have an additional point, or, in other words, that a two-point Tea should rank equal with a three-point Perpetual. I cannot see the justice of such an arrangement; yet if the National Rose Society rule that it must be so I will loyally obey.

I have mentioned "points." There must be points in judging. As there are degrees of excellence in different blooms those degrees must have expression. I fail to see that the point-card system of "H. C." is so tedious as many suppose it to be. I have often seen some of the great judges so puzzled that rough strips of paper had to be called into requisition to "mark" certain blooms. If Roses can be judged without badges numbered 1, 2, and 3, well and good; but I am almost certain that there have been occasions when if the judge had had a bundle of such numbers that he would have been glad to have employed them by way of helping him out of his difficulty.

Hybrid Perpetual and Tea Roses are so distinct, and each section contains so many varieties and colours, that the most intelligible way is to exhibit them in their separate classes. In judging Grapes Black Hamburgs are not compared with Muscats, simply because they are not comparable; neither are Teas and Perpetuals. Teas can only be compared with Teas, and Perpetuals with Perpetuals; if otherwise, exhibitors are at the mercy of the fancy of a "class" rosarian. If the mixed system is to continue I shall vote for Teas to be judged as other Roses. If they are to be considered as belonging to a higher category and to have additional points accorded to them by certain judges, it will be a simple act of justice to exhibitors to publish the names of judges in order that the stands can be arranged to meet the peculiar fancy of a particular judge.—M. N. R. S.

EARLY PEAS.

MY experience with early Peas is in accord with that of your correspondent Mr. A. Campbell on page 132. I sow about the third week in November on a south border, placing the rows 6 feet apart; the space between is occupied during the spring with Radishes and other dwarf-growing vegetables. Like Mr. Campbell I never think of protecting the Peas, as forty years of experience has taught me they do not need it. *Dillistone's Early Prolific*, *Sangster's No. 1*, and *Dickson's Favourite* are the sorts I have grown for a number of years; they come in succession as named. *Prizetaker* sown at the same time and *Laxton's Prolific* a month later afford us a fine

succession till the summer varieties come in. We sometimes suffer from mice (they are watched and trapped), likewise from sparrows and wood pigeons, but a dusting of lime and soot is a very good remedy against them. When the plants are well above ground and the weather is favourable a little soil is carefully drawn to and among them, and when they are sufficiently advanced we stake them. I am of opinion that no one need fear sowing Peas at the time stated without the soil is very unkindly and the situation specially unfavourable. The earliest Peas that I ever gathered in North Yorkshire not far from the sea were Dillistone's Early Prolific sown November 5th, gathered May 6th. The soil and situation were not of the most favourable description.—N.

NOVELTIES IN THE ROYAL GARDENS, KEW.

THERE is scarcely anything more lovely than Xiphion or Iris Histrio, a charming herald of coming spring. Most nearly allied to *X. reticulatum*, it is livelier in colour and abundantly distinct in many particulars. It has erect, glaucous, acutely four-angled leaves, reaching to about 1 foot high, equal to twice the height of the flowers. These are from 2 to 3 inches in diameter; the outer segments or "falls" are spreading, of which the claw is purple and the blade chiefly blue; a golden line runs up the centre of the exposed portion to about its middle, and is decorated with a few small purple spots; from this golden line on a white ground radiate a few bluish-purple streaks, about which are large blotches of the same colour losing themselves on the outside in the pale blue margin; the inner segments or "standards" are lanceolate, pale blue, and erect. It is a native of Mount Lebanon, and has received the manuscript name of *Iris Libani*. To all appearance it is quite hardy, though, from its great rarity, no extreme trial has been made.

Dendrobium Freemanii is a new Orchid introduced by Mr. William Bull, and the plant he presented is flowering for the first time. At first sight it brings a thought of *D. nobile*, but immediately it is seen to be quite distinct. It has the same colours disposed in the same way; the sepals, however, are much narrower, and the lip is rounded instead of having a recurved point, it also has a longer claw. The stems are perhaps still more strikingly different; they are slender and evenly formed throughout, those bearing the flowers have an attractive whiteness from the dried persisting sheaths of the fallen leaves. It was discovered by Mr. Freeman in Assam. *Cypripedium Boxallii* is another new species in flower in this house. In habit and in foliage it is not unlike *C. villosum*, to which perhaps it is most nearly allied, though the flowers readily prove it a distinct species. They give also the idea of *C. insignis*, to which in the lip and the superior sepal it bears some resemblance. The latter is conspicuous in its marking and colouration; over a groundwork of very light green there are many large black-purple spots, and round the outside above is a margin of white. It is distinguished from *C. villosum* by the shorter peduncle, the smaller flower and comparatively larger bract, the breadth of superior lip at the base, the narrow clawed petals, which are obtuse and dilated at the apex, and the obtuse inferior sepal, besides, of course, some other points. It was discovered by Mr. Boxall, after whom it is named, and was introduced by Mr. H. Low.

The next novelty is one of the "princes of the vegetable kingdom"—*Ptychosperma rupicola*, the flowers of which are here expanding for the first time unassisted by the spicy breezes that "blow soft o'er Ceylon's isle." In that island it grows on the lower rocky lands and attains a height of 40 feet. It is of some interest to the natives; they find in the seeds a substitute for those of *Areca Catechu* to chew with their Betel. Besides flowering for the first time this particular specimen has the interest of being the finest in cultivation, and that of one of the most beautiful of all Palms. It was grown from seeds received at Kew about fourteen years ago. It long remained without an apparent stem, but which having commenced growing soon reached a height of over 3 feet, and now the finer fronds are reared to a height of 10 feet. The fronds are pinnatisect, and the diameter of the crown extends to over 8 feet. They form graceful curves in every direction, every part, as it were, aiming at the line of beauty. Armed to the teeth, as in a flight of fancy we may say many Palms are, this, on the contrary, is without a single sharp point. All over the fronds are glaucous, and from their first appearance to full expansion are attractively coloured red. They have great breadth in proportion to length, and, as cultivators say, make

up a "well-furnished" plant. The inflorescence or spadix comes just below the lowest leaf, and is composed of about twelve spicate branches coloured with crimson-red, as if formed of coral. The buds are of the same colour, but the open flowers are pale, showing yellow anthers. They are produced in pairs, and one of each pair on the lower part of each branch is female. This splendid Palm is in the Victoria house.

In the Begonia house are often found many plants of select character. A large number of Gesneraceae have been grown there the past season, one of which, profusely flowering at the present time, appears to be little known, yet it is of great value. This is *Tydea Madame Heine*. All the summer we have watched it occasionally producing a few flowers, and were inclined to think it of little consequence. Now, however, its time has come. It grows about 3 feet high. The leaves are velvety and pale green; the flowers are large, with inflated carmine tube, white or creamy-white lobes, the upper suffused with carmine, and all equally covered with purple-black or deep carmine dots. The roots were planted last spring about three together in a pan, using light soil, and a liberal supply of water during growth has been given, as required by all the order. It is a great mistake to grow these plants so thickly together as often practised; every plant should have room to fully develop. *Achimenes* are often absurdly crowded together, resulting in a flare of colour for a short time, then bearing a few flowers like dying sparks to make the starved leaves conspicuous. These beautiful plants, flowering as they grow, must have sufficient space and food to produce the growth, without which there are few flowers.

A new *Hæmanthus*—*H. albo-maculatus*, contributed by Messrs. E. G. Henderson & Son, now flowering in the Cape house, opens up a new feature in the genus, that of spotted leaves. Of this specimen they are about 14 inches long, strap-shaped, and liberally ornamented with large ivory spots. The flowers are pure white, and, as in other *Hæmanthus*, are produced in a crowded head. The spathe-valves, which in *H. coccineus* are strikingly ornamental from their crimson colour, are in this case white or greenish-white.

VINE BORDERS.

I GENERALLY agree with what "A KITCHEN GARDENER" writes in the *Journal of Horticulture*, as he is evidently a practical man; but though no doubt Mr. Taylor is very well able to hold his own, I cannot but find exception to some of "A KITCHEN GARDENER's" statements about inside Vine borders and the method he recommends for making Vine borders. No person, he says, could rightly understand that by adding one-third of the whole it was applying it in equal parts. Now, adding one cartload of cow dung and one cartload of wood ashes to three cartloads of loam is virtually one-fifth cow dung, one-fifth wood ashes, and three-fifths loam, without reckoning the bushel of smashed bones. Neither again do I think, unless under very exceptional circumstances, that cow dung is the best manure for Vines, and is certainly not so lasting in its effects as well-decayed stable manure mixed with pig manure. Much depends, again, whether the wood ashes are merely the refuse of bonfires and charred vegetable matter or properly prepared charcoal, which, if not overburnt and well broken up, is one of the best materials possible to add to Vine borders if the loam is at all clayey or of a tenacious nature.

As for saying either that all Vine borders should be inside or all outside, both statements would be equally wrong. That many gardeners abstain from giving water to inside Vine borders, especially when the Vines are in a state of apparent rest, is perfectly true; but those who know anything of the natural habits of the Vine know full well that it is during the winter in Vine countries that the Vines receive their chief supply of water, and that the rootlets of Vines are seldom, if ever, in an inactive state. To condemn inside Vine borders because when late Grapes are hanging on the Vines in the winter it is dangerous to give water, is to ignore the fact that it is far easier to cut off the bunches with a sufficient amount of stem attached and to place the stems in bottles of water in a dry airy room where heat can be applied if necessary. This plan has been so often advocated in your columns that it is scarcely necessary to allude to it. "A KITCHEN GARDENER" seems to admit of no medium position between having an inside border saturated with water or dust-dry. Surely either extreme is equally absurd, just as was the old custom of drying-off stove and greenhouse plants at their roots during the winter instead of keeping the rootlets alive by adequate moisture. I venture

to give a hint to many gardeners, "that there is no royal road to gardening;" one soil requires one kind of management and another another. One garden has climate and winds to contend with, another is sheltered and warm. Where I am writing these few lines (at Cannes in the south of France) there are changes both in the soil, subsoil, rocks, stratification, nature of undergrowth, &c., within 100 or 200 yards. Along a new road which is being made I have seen both soil, subsoil, and rock vary in a few yards from soft mica schist with sandy soil to different-coloured mountain limestone with red tenacious clay, varied with soft chalky soil mixed with China clay in small proportions, and in another part hard stalactite-formed limestone which requires to be blasted.

"A KITCHEN GARDENER" is beginning a series of papers on Vegetable Culture, which I have no doubt will be both interesting and instructive, but I hope he will abstain from laying down the law too definitely; as, for instance, where he says, "Any garden above one acre in extent should be surrounded by a red brick wall 9 inches thick and 10 to 12 feet high;" and again, "The basement of the wall should consist of stone up to the ground level, and the bricks which follow this must be substantially and neatly built-in, and the coping should be of dressed freestone placed so as to project about 3 inches on each side," &c. I object strongly to the law being laid down in this sort of way, as if it might not suit better in many cases to have stone walls faced with hollow bricks; or again, to have 13½ brick walls instead of 9-inch, or brick copings properly made instead of dressed stone. The plan, too, of zigzag brick walls for the north wall of a garden has never yet been sufficiently tried, and must eventually be found to answer, as it gives greater strength, more varied aspect, and easier means to protect fruit trees by glass copings and curtains or strong Nottingham net. I do not wish, however, to dwell more upon this point, but hope that when laws are given for vegetable culture, or fruit-tree pruning, or garden walls, garden borders, &c., a little more allowance might in a general way be made for the diversity of soils, aspects, climates, means and capabilities to boot, that different gardeners have to contend with under different circumstances. When gardeners have done their best there are still many important points not under their control, and to the very last there will be different means to the same end.—C. P. P.

OUR BORDER FLOWERS—GLOBEFLOWERS.

GLOBEFLOWERS are an acquisition to our collections of border flowers, and under many circumstances repay us for any labour we may bestow upon them. They are what may be termed late-spring or early summer-flowering plants of dwarf habit and pleasing appearance while in bloom. They are moisture-loving plants, bearing full sunshine and partial shade. What we call our own European Globe-flower (*Trollius europæus*) is one of the most beautiful field flowers we possess. It is found in moist upland districts, often by brooks in out-of-the-way places. The white variety of the above is a very interesting plant, and ought to be much more cultivated than it is. They are fine plants for open spaces in half-wild places by the side of ornamental waters and moist woods. We are told that the Swedes in holiday time strew them about their doors; while drying they give off a delicate perfume. The American Globe-flower (*Trollius americanus*) one of the dwarfiest of the tribe, is of pleasing habit, and is a desirable and useful border plant, also effective on a large rockery. *Trollius napellifolius* is much like *europæus*, but of deeper colour. *T. patulus* deserves more attention than it receives; it is of a pleasing orange colour. The Siberian Globe-flower (*T. asiaticus*) is the most attractive of the family, having deep orange-coloured flowers. Where a group of them are planted together and cared for they make a fine bed in the spring and early summer. They are not particular as to soil. A good loam and decayed vegetable matter with moisture when they need it will meet their requirements. They are increased by division after flowering. If left till the spring the crowns are liable to be injured.—VERITAS.

RASPBERRIES.

I WANT to ask a question on the subject of "WILTSHIRE RECTOR'S" remarks on this fruit. He says that ground becomes Raspberry-sick, and that hence they must not be grown too long in the same place. Is this so? because if it be it runs counter to all I have ever been taught on the subject.

I remember dear old Weaver, the Warden's gardener at Winchester, showing me Raspberry quarters which he believed to be nearly a hundred years old; and I have always understood that they would stand any length of time, provided they received reasonable cultural attention. Mine have succeeded for nearly nine years, and I thought they would last my time. Will some fruit-grower kindly answer me this question?—D., Deal.

[We are acquainted with a healthy and fruitful plantation of Raspberries that is upwards of forty years old. We shall be glad to hear what other cultivators have to say on this subject.—EDS.]

ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 19TH.

ONLY a small quantity of fruit was exhibited on this occasion, but extensive and valuable collections of plants were staged, and the Council-room, which was quite filled, had an exceedingly gay appearance.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P., in the chair. Mr. E. Robbins, gardener to Sir E. A. Lechmere, Bart., Rhydd Court, Upton-on-Severn, sent a dish of Easter Beurré Pear remarkably well kept and of excellent flavour. A cultural commendation was awarded. Major Mason of Warwick sent specimens of two varieties of seedling Apples, one raised from Bess Pool and the other from Dumelow's Seedling. The former though long past its best had every indication of being a good dessert Apple, but the latter was not considered to possess any great merit. The Committee expressed a wish to see the former another year in better condition. A letter of thanks was awarded to Major Mason. Mr. B. Johnson, gardener to T. T. Clarke, Esq., Swakeleys near Uxbridge, sent a dish of Golden Knob Apples in fine condition, to which a letter of thanks was awarded. Mr. Francis Dancer of Little Sutton sent a dish of the following varieties of Apples: Reinette de Caux, Braddick's Nonpareil, Cox's Orange, Dumelow's Seedling, and Golden Reinette, to which a letter of thanks was awarded. Mr. B. R. Davis of the Nurseries, Yeovil, sent a dish of bulbs under the name of Davis' Prize Jersey Shallots, which were the Potato Onion. Colonel Trevor Clarke sent specimens of his Red Solid Celery, which was pronounced by the Committee to be the finest Celery in cultivation.

FLORAL COMMITTEE.—Mr. Noble in the chair. Messrs. James Veitch & Sons exhibited a beautiful collection of Orchids, amongst which were *Angræcum sesquipedale* with six flowers, another plant having four very fine flowers; *Cattleya Trianae*, *C. Trianae alba* very pure, and *C. Trianae Penelope* distinct from its pleasing colour and undulated sepals and lip. *Odontoglossum Alexandræ* was represented by vigorous spikes, also *O. prenitens*, *O. triumphans*, *O. cirrhosum*, and *O. Chesteri*, which appears intermediate between *O. Alexandræ* and *O. gloriosum*. *Angræcum citratum* was very lovely, as also was *Odontoglossum Roezli album*. The small *Oncidium cheiroporum* was effective by its bright yellow flowers, and extremely curious was the grotesque *Masdevallia chimera*. *Bolbophyllum aurioconum* is a singular small Orchid, as also is *Dendrobium endocharis*. Several *Cypripedium* were included in the group, also *Sophronitis grandiflora*, the charming orange-buff *Rhododendron Duchess of Teck*, heads of the double *Poinsettia*, and a collection of very fine *Cyclamens*. A botanical commendation was awarded to Messrs. Veitch for *Aërides vandarum*, a remarkable species from India. The leaves are quite round and somewhat resemble spines, about the eighth of an inch in diameter and 6 inches in length; the flower is pure white, and from its singular formation almost resembles a double flower. A small silver medal was recommended for the whole collection.

Mr. Wills contributed an attractively arranged group. The base was composed of *Lycopods*, *Spiræas*, and *Lilies* irregularly arranged, with which were associated Orchids—excellent spikes of *Odontoglossum Alexandræ*, *Phalenopsis Schilleriana*, *O. cirrhosum*, *O. gloriosum*, *Lælia anceps*, and *Dendrobium glumaceum*, under a canopy of *Palms*. A vote of thanks was recommended for the collection.

Mr. B. S. Williams sent a collection of very choice Orchids, consisting of *Masdevallia ignea*; *Odontoglossum Alexandræ*, *cirrhosum*, and *Rossii major*; *Dendrobium Wardianum*, very fine; *D. cuculatum giganteum*, and the new and distinct *D. superbiens*, which has continued in bloom for ten weeks, a fact which must enhance the value of a valuable plant. *Cypripedium insigne Maulei*, *Tricoplia suavis*, and *Cattleyas Walkeriana* and *Trianae* were attractive. Mr. Williams's collection also included some bright and good *Amaryllises*, *Sarracénias*, *Habrothamnus elegans argenteus*, and *Palms*, several plants of an excellent variety of *Solanum* with numerous large bright berries, also some highly superior *Primulas*. The old white and rosy-purple varieties are not easy to surpass in their respective colours; and the new scarlet variety, *Primula sinensis fimbriata coccinea*, was awarded a first-class certificate. The plants are equally robust, and the flowers are of the same size and substance as the others, but the colour is a bright magenta.

which will have the important property of being effective by gas-light, and can thus be employed for decorative purposes where the ordinary dark Primulas present a comparatively pale appearance. Mr. Williams further exhibited plants of *Dracena Renardii*, one of Mr. Wills's new varieties; *Croton Jamesii* and *C. falcatum*, both of which are distinct; and admirably grown table plants of the still valuable *Dracena terminalis*. A bronze medal was recommended for the entire collection.

Messrs. Osborn & Sons, Fulham, staged an extensive and excellent group of ornamental-foliaged and general decorative plants, consisting of Palms, Crotons, *Dracenas*, *Pandanuses*, Ferns, *Azaleas*, *Spiræas*, &c. The plants were remarkably clean and healthy, and were attractively arranged. A small silver medal was recommended to be awarded to Messrs. Osborn.

Messrs. John Standish & Co., Ascot, exhibited splendid pots of Lily of the Valley. The flowers were almost as closely arranged as in a bouquet, but it is only fair to say that they had evidently been packed and not grown in the pots. The same firm also exhibited admirably grown and flowered plants of *Chorozema cordatum* splendens which were extremely effective, also *Azalea mollis*, and forced plants of *Hippolyte Jamin Rose*, which is evidently a valuable variety for early flowering. A bronze medal was awarded.

Messrs. W. Paul & Son, Waltham Cross, exhibited a plant of the pure white *Camellia Ninfæ Egeria*, very smooth and good, and with rich dark foliage; also cut blooms in upwards of fifty varieties, which were arranged in moss after the manner of exhibiting Roses. The varieties were superior, and the effect produced excellent. A bronze medal was recommended for them.

Mr. William Bull was awarded a first-class certificate for *Hæmanthus rupestris*, received from the west coast of Africa, which is decidedly richer in colour than *H. cinnabarinus*. Mr. Bull also exhibited a few other new plants.

Messrs. Rolliason & Sons were awarded a botanical commendation for a miniature Orchid, *Saccolabium Calceolaria*.

Mr. Cannell, Swanley, sent plants of his new *Geranium Salmon Vesuvius*, a variety which, from its pleasing colour and extreme floriferousness, cannot fail to become popular; also cut blooms of *White Vesuvius*, the fame of which may be said to be firmly established; also Dr. Denny, a richly coloured flower, purple lake suffused with crimson.

Mr. Charles Edmonds, Hayes Nursery, Middlesex, exhibited an extremely fine collection of Cyclamens. The plants were admirably grown, and the varieties were varied and excellent. A first-class certificate was awarded to *C. persicum Roseum Grandiflorum*. It is a very free-growing and flowering variety, having flower stems a foot in length and well-formed flowers, deep eatiny rose-and-crimson mouth. It is a very fine variety. Mr. H. B. Smith, Ealing Dean Nursery, also staged an excellent collection of Cyclamens, some of which had very large flowers. A first-class certificate was awarded to *Rosy Morn*, deep rose faintly suffused with purple, a medium-sized flower of a distinct and pleasing colour. Mr. James, gardener to W. F. Watson, Esq., Redles, Isleworth, was awarded a first-class certificate for a very fine pure white Cyclamen, appropriately named *White Beauty*. The plant is robust, the flowers large and well formed, and the colour pure. Mr. James also staged about a hundred plants of new seedling *Cinerarias*, which commanded much attention. The plants are of sturdy growth and are varied in colour, some of the colours being very soft and others extremely rich; the flowers are also well formed and possess great substance of petal. A rule of the Society precludes certificates being awarded to seedling *Cinerarias*, but a bronze medal was recommended for the collection.

The Hon. and Rev. J. T. Boscawen, Tregothnan, Cornwall, exhibited a plant of *Amaryllis Temeraire*, an excellently formed flower of a glowing vermilion colour, and received a vote of thanks. H. J. Elwes, Esq., was awarded a cultural certificate for *Narcissus monophylla*. Mr. G. F. Wilson exhibited a *Primrose* named *Scott Wilson*, which was distinct from its bluish-plum colour. Some surprise was manifested that a plant having a colour so new and so rich did not receive some mark of recognition. Mr. Dean also staged two pretty *Primroses*—*Virginia*, white; and *Attraction*, purplish mauve. Mr. Johnson, gardener to T. T. Clarke, Esq., Swakeleys, Uxbridge, exhibited admirably grown plants of the fragrant *Daphne indica rubra*. They were nearly 3 feet through and high. A cultural commendation was awarded.

Mr. Winn, gardener, Wood Street, Birmingham, had a vote of thanks awarded for a richly spotted variety of *Odontoglossum Alexandræ* var. *Winnii*. Mr. Ollerhead exhibited a very fine variety of *Odontoglossum Alexandræ*, the spike having thirteen flowers. The same plant was exhibited last year with twelve flowers. Mr. Melville, gardener to the Duke of Sutherland, exhibited *Snowdrops*, including *Dunrobin Seedling*, a large pure white flower; and Mr. Tillery, gardener to the Duke of Portland, was awarded a vote of thanks for cut blooms of hardy hybrid *Azaleas*.

Mr. T. Wilkinson exhibited his new *Pea trainer*, the framework of which is made of wrought iron, with feet flanging outwards, so that the trainer can be firmly fixed without injuring the roots of

the Peas; the growths are supported by wire affixed to the standards. The meeting was a highly successful one.

DURING the afternoon a large number of horticulturists and visitors assembled in the Council-room, where Mr. Jennings, the Assistant Secretary, delivered an admirable lecture on the Cyclamen, the chair being occupied by Col. Trevor Clarke. In commencing his remarks Mr. Jennings observed that as it had been suggested that the meetings would be rendered additionally interesting and instructive by addresses on the history and cultivation of various plants, he was prepared to carry out the suggestion, trusting to the aid that he felt sure would be readily rendered by nurserymen and amateurs in supplying specimens, and otherwise giving valuable co-operation in carrying out the object proposed.

As a genus the lecturer observed that the Cyclamen is confined to the countries bordering on the Mediterranean—South Europe, West Asia, and North Africa; it could, therefore, scarcely be considered an English plant, although as being found growing in some Kentish woods it may be regarded as naturalised. Two of the hardy species, *C. coum* and *C. hederæfolium*, were cultivated in Gerard's garden as long ago as 1596, and *C. persicum* was introduced by Sibthorpe from the Isle of Cyprus in 1781. The original *C. persicum*, although very beautiful by its pure white flowers and graceful habit, is far eclipsed by the magnificent specimens now exhibited in the room. After alluding to the confusion existing in the nomenclature of the species, and after pointing out errors, such as the figure of *C. hederæfolium*, *Bot. Mag.*, 1001, which is really *C. vernum*, and that the same plant was figured by Sweet as *C. repandum*, also that the same writer has figured *C. ibericum* under the name of *C. vernum*, Mr. Jennings remarked that for all practical purposes the number of species might be reduced to six—namely, *C. coum*; *C. ibericum*, including *C. Atkinsii*; *C. vernum*, including *C. repandum*; *C. europæum*; *C. hederæfolium*, with its geographical forms of *C. africanum* or *macrophyllum*, *C. græcum* or *latifolium*; and *C. persicum*. The various points of distinction were alluded to, and the different species were lucidly described. These descriptions, with practical notes on the increase and cultivation of the Cyclamen, will appear in the forthcoming number of the Society's Journal. In concluding his lecture Mr. Jennings acknowledged his indebtedness to Mr. Little of Hillingdon, Mr. Tyerman, Mr. Atkins, and Mr. Barr, who had supplied specimens and imparted much valuable information, which he had incorporated in his address.

The address was listened to with great attention, and a cordial vote of thanks was proposed to the Assistant Secretary by Mr. G. F. Wilson. More of horticultural life pervaded the Council-room than has been observed for some time past, and it was generally admitted that the proposed series of addresses would be of great benefit to the Society and to horticulture generally.

Ten new Fellows were elected during the afternoon.

THE OLD MARKET GARDENS AND NURSERIES OF LONDON.—No. 19.

IN again taking up the locality of Chelsea, a suburb once so greatly favoured by the nobility and gentry as to be called a "village of palaces," I would remark that I hope no reader of the previous article fell into the misapprehension that I had said all that needed to be said or all I knew about the nurseries there. A division was necessary, and now in completing I gladly make some corrections which further researches have put in my way, and also acknowledge publicly the valuable information kindly given by Mr. John Weeks of Temple Dinsby, Hitchin. In the first place I note that I erred in the supposition that the ground at present occupied by a Roman Catholic convent and school in Cadogan Street was at one time part of the land belonging to the King's Road market gardeners. It was, before it was built upon partially, the Wellington cricket ground, and tracing back the history of this plot to the eighteenth century it seems then to have been the garden attached to an "ancient house," the property of Lady Matthews, abutting on the Marlborough Road, then a circuitous rural lane. It has recently been stated in the sketch of the life of John Fraser, nurseryman and traveller, that appeared in these pages, that his nursery occupied ground subsequently taken by Government for the Royal Military Asylum; it appears also that he called his establishment an "American nursery," but it must be distinguished from the American nursery in Sloane Street already spoken of connected with the historic names of Curtis and Salisbury. Nor was Fraser's the establishment afterwards known as "Whitelands," as the former had ceased to exist about 1810, while the latter flourished to a later date. It had not much extent of ground, its frontage to the King's Road being the small block of houses between the old "Hemus Terrace" and "Whitelands House," now a training school. That part of the King's Road which

runs along the centre of Eaton Square is not in the line of the old thoroughfare which went across the "Five Fields" at a considerable angle past Belgrave Square, sweeping round again into Sloane Square, during the time good George III. used to traverse it frequently on horseback. Though the greater part of the "Five Fields" was open or common land, a Mr. Jenkins had some 15 acres in cultivation up to the time the squares began to be formed which lie between Sloane Street and the Knightsbridge road. Allusion has been made to the nursery of Messrs. Allen & Rogers. The position of this was, I find, just opposite the present Eaton Chapel and Coleshill Street, as an old resident informs me, who remembers that street when it was a road with a ditch on each side. When Mr. Moore's nursery, just beyond Colvill & Davey's, was taken for building purposes Mr. Moore removed to the opposite (south) side of the King's Road at the corner of Radnor Street, where the business was carried on some years longer. "Little's Nursery," now much diminished in extent, has been in the same family for three generations; it is chiefly devoted at the present time to the production of "Chinese Moss." The frontage of Mr. Rolle's nursery extended from "The Six Bells" to the corner of "Cook's Ground," as it was formerly called, the land being now intersected by Oakley Street. Mr. Rolle's ground stretched back some distance, but it did not reach to the bank of the river. The old appellation, "Cook's Ground," given to what is known as "Glebe Place," a circuitous street running from the King's Road to Cheyne Walk, suggests that it had the name from some former owner, though none of the local historians have given any account of a person to whom it might be traced.

A small chapel in this street is interesting because it carries the memory back to the time when there was quite a cluster of French gardeners in Chelsea, employed in its nurseries and gardens. These were of Huguenot extraction, belonging to those refugees who were driven from their homes by the severe edicts issued against them, and found a welcome shelter in England. Dr. King, the antiquarian rector of Chelsea, has spoken in high terms of their behaviour; from him they received much kindness. The entrance to Cook's Ground, we may infer from an examination of the old maps of Middlesex, was originally a back way to the gardens of Alston House, one of those old palatial residences overlooking the Thames which made Chelsea famous. A few hundred yards down, before the road bends to the right, is the chapel aforesaid, in the erection of which the French gardeners and other Huguenots were concerned. Mr. Roll, or Rolle, was, I presume, a Frenchman. Another Frenchman had an establishment a short distance down Cook's Ground towards the west. The house once belonging to that nursery was not pulled down till 1867 or 1868. This was a Mr. Pamplin, or Pamphillon, some of whose descendants are still resident in Brompton. Across Church Street, or Church Lane, to the west of Cook's Ground, and occupying the space to the road leading to the bridge, was the nursery and market gardens owned by Mr. Shepherd, of whom no local recollections survive; we are therefore left dependant on the Chelsea historian, Faulkner, for facts about one who is said to have been celebrated in his time. He tells us that "Mr. Shepherd first introduced into this country the Italian mode of horticulture, of which his garden, as represented by Kip, was a beautiful specimen." Danvers House and its gardens had occupied the land he cultivated at an early period, and portions of the remains of this old residence were unearthed during some gardening operations in 1822; apparently it had never been pulled down, but suffered to fall to decay. A large stone bath had been brought to light and part of a row of columns. Mr. Shepherd, however, did not care for having investigations pushed further on his property, so these were covered up again. Danvers House was about the site of the present Paulton Square. Subsequently some of the ground owned by Mr. Shepherd was cultivated by Mr. Lamer; it is now all enclosed, as also the land opposite on the north side of the road. On this now stands the factory of Messrs. Ransome & Co., engineers. The previous possessor was the late Mr. Edward Weeks. In 1816 this gentleman, in conjunction with Mr. Parkinson, established a nursery on the ground now occupied by Messrs. J. Weeks & Co., horticultural builders. About ten years after the firm took the strip of the King's Road between Upper Church Street and Sion Place, and here Mr. E. Weeks obtained his first patent for improvements in horticultural buildings, and what had been a nursery was converted into a large factory when he took out a second patent for apparatus by which conservatories could be readily heated through the agency of

hot water. A removal was made, however, in another ten or twelve years to the former site of Davey's nursery, nearer town, which is still held by the firm trading as J. Weeks and Co.

The Vale Nursery, a little to the west, belonging to Messrs. Tebbutt, is still in existence, but it does not cover much ground; in its rear it abuts on Chelsea Park, now cut up for building. As you turn down the lane leading to this nursery you might fancy yourself in the Chelsea of fifty years ago. There is an air of quiet about the place; a double row of Poplars casts a shade, and the houses, only slightly railed round, have grass plots and shrubberies, which give a rural aspect. The nursery itself at the end of the "Vale" looks as if it had been planned a good while since, and when I saw it, displayed in one corner some drooping Hop vines, which looked as if their (probably) venerable age was likely to close speedily; it is a plant that London smoke affects unfavourably. Vainly did I seek in Chelsea Park, fast becoming unpark-like, for any of the Mulberry trees which in 1721 some enterprising persons planted in this park with the view of initiating an English silk-producing factory. This company erected houses in which the silkworms were to be fed, and they had also looms fixed, but unfortunately financial ruin loomed in the distance, for, as Faulkner sagaciously remarks, "either the expense was precipitated too fast, or contributions did not arrive fast enough," and the Mulberry ground became Chelsea Park. Before the silk speculators had it, however, the land had been attached as a park to Wharton House.

Returning to the King's Road it should be noted that the establishment of Messrs. Weeks & Co. near Cremorne, to which I have alluded, passed from Mr. E. to Mr. J. Weeks, and about the year 1845 the latter erected the conspicuous series of buildings fronting the King's Road which is now occupied by Mr. W. Bull. Adjoining Mr. Weeks's nursery and opposite Cremorne Gardens was the nursery ground owned by Mr. Shailer, which extended some distance towards Brompton; its frontage is stated to have been from Slaidburn Street to Edith Grove. Mr. Shailer was known as an extensive cultivator of the Moss Rose. He was succeeded by Mr. Dennis. This nursery disappeared about 1860.

We now come to a noted establishment founded by a nurseryman whose name must rank high on the list of our celebrated horticulturists—viz., Mr. Joseph Knight. Before coming to Chelsea he had been engaged at Clapham, but in 1808 he purchased some acres of land at Chelsea to the west of Messrs. Weeks's establishment, and began to erect plant houses thereon, every year nearly witnessing some increase or enlargement in the buildings. In 1845 he associated with himself a nephew, Mr. Perry, and in 1853 a handsome entrance was made into the gardens from the Fulham Road, and a glazed passage enabled visitors to walk direct into the old conservatory in the King's Road. It is remarkable that this was the first nursery in which an aquarium was erected by Messrs. Gray & Ormson. The square of this tank was devoted to the Victoria Regia, the corners to the species of Nymphaea, and about 5 feet at one end to Nelumbium, Papyrus, and tall aquatic plants. Some time in 1850 this firm bought land at Battersea for Brookland's nursery, where about 12 acres were curiously laid out in square or oblong plots of uniform size. American plants were made a speciality by Messrs. Knight & Perry. It speaks well for the firm that the principals, desirous to promote intellectual improvement amongst their gardeners, had a study fitted up with books, drawing materials, and chemical apparatus. The well-known firm of Messrs. Veitch & Sons has had the establishment in their hands since 1853.—C.

NOTES AND GLEANINGS.

SOME alterations and improvements have recently been carried out in the grounds of the CRYSTAL PALACE by Mr. Thomson, with the result that a better effect has been produced while labour has been economised. The chain beds on the principal terrace have been isolated, and are thus more distinct, and mowing can be more expeditiously done now the connecting links are removed. The series of large oblong beds by the side of the south terrace walk have been turfed over, and the additional lawn is so welcome as affording relief to the preponderating masonry and broad gravel walks, that he would be a bold man who would propose that bright colours should again occupy space where repose is so greatly needed. The two large beds flanking the central flight of steps from the terrace have been planted as "arborescent beds." During

previous years these beds have been arranged as carpet beds or as succulent beds, but their position as sloping from the walk did not show the plants to advantage. They are now edged with *Euonymus radicans variegata*, with an inner line of *Erica carnea*. A series of half-circles are planted with very small plants of the different *Retinosporas*, and the centre of the beds are filled with larger plants of choice Conifers. This mode of planting will afford an agreeable change from the flower beds, which are sufficiently numerous at "the Palace."

— A VERY fine display of *PRIMULAS* is now produced in the nurseries of Messrs. James Carter & Co. at Perry Hill. The plants are grouped in upwards of a dozen varieties, the more distinct of which are the following:—Carter's Perfection, pure white flowers 2 inches in diameter and of great substance; habit of plant robust. Carter's Prize, pure white, more dwarf than the preceding variety; excellent. Fern-leaved, white; as a rule the flowers are not equal to the others. Marginata, rosy lilac, shaded and fringed with white; attractive. Village Maid, white, striped and spotted with rosy purple flowers; good. The principal dark varieties comprise Carter's Prize, deep carmine, rich colour, large flowers; robust and good. Semi-double Carmine, very effective and lasting. Carminea alba, carmine, dotted with white, and crimson centre; distinct but not so free as some others. New Scarlet, pale scarlet, large and very good; good grower. *Rosea floribunda*, rosy carmine; free and effective. Exquisite, rosy purple; good colour. *Carminata oculata*, carmine purple, crimson centre; fine spike and flowers. *Rosea superba*, rosy carmine; lively and bright. The above varieties represent an excellent strain of these popular winter flowers. The nursery now consists of nearly thirty large houses and a great number of frames. Bulbs are grown in immense numbers, and bedding and general decorative plants are extensively cultivated. To meet an expanding trade additions have been made to the "ground department," and large collections of Lilies, Irises, and Roses have been planted, besides shrubs and general nursery stock.

— A POINT of some importance in *KEEPING FLOWERS AFTER BEING CUT* is, writes an experienced gardener, to place them thinly in pure fresh water. In flattish glass baskets he has used sand and clay for keeping the flowers in position, but he finds nothing better for this purpose than small branches of *Laurustinus*, *Arbutus*, *Mignonette*, and other sprays, according to the season. In packing flowers to travel per post or rail these are placed in layers in tin boxes without any packing material. During the summer months the insides of the boxes are damped, but this is scarcely necessary at this season.

— THE most successful instance of raising *DRACÆNAS FROM SEED* that we have seen in a private establishment is in the garden of C. Seely, Esq., M.P., at Furzedown Park, Tooting. Mr. Laing by flowering and intercrossing a few plants has obtained a great number of new varieties which, although of no great value for commercial purposes owing to a richly stocked market, are yet extremely useful for home decoration. It is singular to note the striking difference of varieties of the same parentage, some of the plants having graceful slender foliage not more than half an inch broad, others medium foliage of 1 to 2 inches wide, and a few with broad robust leaves; the colours also are greatly varied, and a few of the varieties may yet "turn out something good." Seedling plants are more free in growth than plants raised from cuttings, and this mode of raising a supply of decorative plants is worthy the attention of gardeners who have a great demand for such plants. The intercrossing of any two distinct sorts is almost sure to result in a great number of varieties of decorative value.

— A PLANT, writes "R. P. B.," which is of the greatest use is *SCHIZOSTYLIS COCCINEA*. I do not intend to grow this any more in pots. By simply matting up large clumps the quantities of spikes supplied therefrom have brought the potting system into disfavour. I intend placing the clumps together this spring, and having a rough framing covered with glass prepared for their protection in succeeding winters.

— AN amateur, whom we know to be a successful cultivator, has sent us a list of thirty-six varieties of *ROSES* which he has found to succeed well near "smoky London." They are placed as near as possible in the order of merit. We publish the selection, as we frequently have inquiries relative to *Roses* suitable for planting near large towns. Charles Lefebvre, Alfred Colomb, Marie Baumann, Baronne de Rothschild, Louis Van Houtte, Mdlle. E. Verdier, Marie Finger, Comtesse d'Oxford, La France, John Hopper, Mdlle. Victor Verdier, Sénateur Vaisse, Etienne Levet, Marquise de Castellane, Xavier Olibo,

Duke of Edinburgh, Dr. Andry, Edward Morren, Mdlle. Marie Rady, Dupuy Jamain, Horace Vernet, Lord Macaulay, Pierre Notting, Paul Neyron, François Michelon, Victor Verdier, Jules Margottin, Emilie Hausburg, Prince Camille de Rohan, Ferdinand de Lesseps, Camille Bernardin, Madame Lacharme, Comtesse de Serenye, Beauty of Waltham, Capitaine Christy, and Duke of Wellington.

— WE have observed in some villa gardens in the suburbs of London that *GERANIUMS* which have not been removed from dry and sheltered borders are pushing fresh growth from the old stems, some of the young leaves being an inch in diameter. This affords evidence of the mildness of the winter, but the chances of the plants escaping destruction by the frosts of spring are exceedingly remote, as the plants in their present state succumb to even a few degrees of frost.

— THE increasing popularity of *TUBEROUS BEGONIAS* can nowhere be better appreciated than in a nursery where special attention has been devoted to their increase and culture. Mr. John Laing of the Stanstead Park Nursery, Forest Hill, has been a successful raiser of these plants, and his stock of them almost equals that of the *Phloxes*. Mr. Laing finds it of great importance that the tubers be kept moderately moist during the resting period, or they do not start freely in the spring. They are started in gentle bottom heat, and as soon as signs of growth are apparent they are carefully packed and dispatched for summer duty.

— ONE of the finest plants of *EUPHORBIA AMAZONICA* that has come under our notice is now flowering in the conservatory of Mr. B. S. Williams at Holloway. The plant is in a large pot, and is as healthy as it is floriferous. It is 4½ feet in diameter measuring through the foliage, and is supporting forty-two flower spikes containing two hundred expanded flowers and unopened buds. It is an admirably grown specimen. Two grand plants of *Imantophyllum* are also showing flowers in the same structure, and will shortly contrast effectively with the noble Palms, Tree Ferns, *Araucarias*, &c., with which they are surrounded.

— THE death, at the advanced age of eighty-three years, of the well-known Swedish botanist PROFESSOR FRIES, of the University of Upsala, is announced.

— WE regret to announce the death of Mr. JOHN KEYNES of Salisbury, which took place on Sunday last, the 17th inst., in his seventy-third year. After Mr. Lidgard's death Mr. Keynes was regarded as the senior member in the florists' ranks. He commenced his career as a florist by cultivating *Pinks*, and his friends know how ardently he prosecuted the cultivation of that and other flowers, how he surmounted obstacles that beset his path, and how he at length achieved success. He was not only a skilful cultivator and a formidable competitor in the exhibition tent, but was a successful raiser of new flowers. During the latter years of his life he devoted his attention chiefly to the cultivation of *Roses* and *Dahlias*, and florists are indebted to him for many new and splendid varieties of the last-named flower. Last year alone eight of his *Dahlias* obtained certificates—namely, Bessie Ford, Charles Wyatt, Dictator, Emulator, Marian, Robert Burns, The Countess, and Louisa Neate; and upwards of ninety other varieties of *Dahlias* of Mr. Keynes' raising are enumerated in Mr. Turner's catalogue—a noble heritage; indeed, we believe that of its kind it is unexampled. Mr. Keynes was not only held in great esteem by all florists, but was honoured by those who by close contact with him were specially able to estimate his worth, an estimate which found expression in his election to the honourable position of Mayor of Salisbury.

INSIDE VINE BORDERS.

IN your impression of February 7th a grower of two hundred Vines condemns inside Vine borders for late-keeping Grapes as Lady Downe's and Gros Colman. Having had some experience in growing late Grapes I find no difficulty whatever in keeping Lady Downe's grown in inside borders. I for years have had the management of early and late vineries, and have generally made them to shake hands as it were—that is, send the last dish of Lady Downe's to table one day, and cut Black Hamburgs the next—that is, I have had new Grapes the first week in April, and have had no difficulty in keeping Lady Downe's plump and good. At present not having Lady Downe's planted inside I have this year grown them in pots and have still some left in good condition. I have no hesitation in saying, provided the borders have sufficient water during the growing season, no

difficulty will be found in keeping Grapes until the time specified.—G. TUCKER, *The Gardens, Clock House, Putney Heath.*

CAPE HEATHS.—No. 2.

FEBRUARY.

IN commencing the cultivation of *Ericas* the first thing to secure is drainage; and as the roots of these plants cannot have any sour or stagnant matter lying about them without materially affecting their health, drainage must be thorough and effectual. As a safeguard we have frequently adopted a system of placing extra drainage in the pots, so that if the water should be poured in by any young or thoughtless person with a somewhat heavy hand no ill effects will accrue. The simple operation of draining, or, as it is commonly termed,

"crocking a pot," although of the most vital importance to the future well-being of the plant, is nevertheless not a subject which can be made interesting to the reader. Suffice it to say that about an inch deep of broken potsherds should be placed in small pots in which these plants are to be grown, the quantity increasing up to 2, 3, or 4 inches as the diameter of the pot increases; the whole should be covered with a good layer of the rough fibre which has been knocked out of the peat in preparing it for potting.

Passing from drainage we next come to soil. This should consist of good fibrous peat and sharp gritty sand, in the proportion of about three portions of the former to one of the latter, although the operator must be guided to some extent in this matter by the amount of sand naturally in the peat. As before remarked, good fibrous peat should be selected, but we do not prefer the very light fibry sort, such as is usually sought

Fig. 22.—*Erica bruniades*.

Fig. 23.—*Erica elegans*.

for by the Orchid-grower, because this is much too light; but if to this sort is added an equal quantity of a heavier kind having less fibre, then a superior compost will be obtained suitable for the cultivation of either hard or softwooded *Ericas*. In choosing a heavy peat carefully avoid a dark black kind, which becomes hard when dry, and as it decays turns to a soft sour mud; this sort of peat is, moreover, always very poor.

We dislike the use of the sieve in preparing soil, and should recommend it only to be employed in extreme cases; nevertheless, the peat must be chopped and broken up into small pieces suitable to the size of pot to be used, as ordinary common sense should teach the operator that it is quite essential to use coarser soil for a plant which is to occupy, say, a 12-inch pot, than one only 6 inches in diameter. In the case of specimen plants it will be found beneficial to mix with the compost small pieces of sandstone, charcoal, or even broken pots, as they serve to keep the soil open and porous, and thus conduct the superabundant water rapidly away, which in the case of specimens occupying the same pot for some years requires consideration; for, as the fibrous portion of the peat decays, the soil without this assistance is liable to become hard

and close, and by thus retaining the water it becomes sour, to the great detriment of health, and oftentimes speedily causing the death of the specimen.

All the *Ericas* mentioned on page 25 are still flowering, although *E. gracilis* is now getting past its best, and will soon require to be cut close back, kept a little close until breaking, and repotted for the coming winter months. A few of the best kinds now flowering are:—

E. bruniades.—This is a little gem for flowering at this season, although it does not receive the attention it deserves from the hands of either gardener or amateur. The habit is compact and branching, leaves linear-oblong; whole plant covered with long white woolly hairs. The flowers are pink with jet black prominent stamens.

E. elegans.—A distinct and handsome species, belonging to the section which can only be successfully increased by seeds. Its calyx being coloured renders it very attractive long before the bloom is expanded, and thus its period of beauty is greatly prolonged. Leaves linear-acute, densely glaucous, rendering the plant at once conspicuous from its allies. Flowers in terminal umbels of four to six. Calyx and corolla bright

rose or rosy pink, the tube being tipped with green at the apex.

E. echiniflora.—In habit of growth this plant somewhat resembles the vestita section. Leaves linear-acute, arranged in irregular whorls of five to six. Flowers produced in many-flowered terminal whorls; tube short and inflated, colour rosy-purple. It lasts long in beauty, but is not well adapted for cutting for bouquets.

E. Lambertiana rosea.—A compact-branching plant of free growth. Leaves linear-obtuse, quite smooth, and bright green.

Fig. 24.—*Erica Lambertiana rosea*.

Flowers produced near the ends of the small branches, globose, with a contracted mouth, shining white suffused with rose, glutinous. A handsome kind, which is very effective either in the plant house or when cut for bouquets.

E. scabriuscula.—A free-growing softwooded species which bears cutting well, oftentimes called an April and May bloomer; we have, however, more frequently seen it commence flowering about the end of January, and during the present month is mostly at the height of its beauty. Leaves oblong-obtuse, dark green on the upper side, paler below. Whole plant clothed with rough glandular hairs. Flowers campanulate, pure white, produced in great profusion.

E. Vernix coccinea.—This desirable and very showy plant is again finding favour with the plant-loving amateur, and it is truly quite surprising why it ever became slighted. Leaves arranged in threes, subulate, dark green above, furrowed below. Flowers produced in profusion from the points of the small branches, usually arranged in threes, and forming a long raceme; colour fiery red, glutinous and shining. Although very glutinous, flowering as it does at this early season of the year, it does not become disfigured with dust, flies, &c., which so often mar the beauty of some of the best kinds later in the year.—W. H. G.

ROSE SHOWING.

FOR the encouragement of "A LOVER OF ROSE SHOWS" I pen the following, assuming that he, like myself, has but a limited space for cultivation. I have about 40 poles of garden ground devoted to fruit, flowers, and vegetables, including about one hundred Rose trees, from which I cut a stand of twelve blooms that (after being exposed to a thunderstorm the day and night previous) took third prize at the National

Rose Show on the 4th of June last. I think I may safely say that Mr. Smallbones, the winner of the cup in the same class, has no more space, and I remember his telling me when we met at the Huntingdon Show that he had about the same number of trees as myself. I do not disbud severely, as I am able to cut a basket of Roses any day during the flowering season, and have been a successful exhibitor at provincial shows. I have written the above simply to encourage amateurs with limited space and young beginners.—D. SEWELL, *St. Neots, Hunts.*

NOTES ON VILLA AND SUBURBAN GARDENING.

FORMATION OF LAWNS.—Perhaps there is no part of a garden that attracts the attention of foreign visitors to this country so much as a well-kept and verdant lawn. The changeableness and other peculiarities of an English climate are said to have much to do with bringing about this important feature to all grounds set apart for pleasure, but notwithstanding these advantages we often find lawns after an interval of a few weeks of drought become burnt and patchy from the very fact that sufficient attention had not been paid to their formation. The work of levelling is oftentimes done too hurriedly, the soil from the hillocks is merely removed and placed in the hollows without sufficient thought being given to its settlement or the necessity for enriching the higher ground, the subsoil of which has been laid bare—both of which are fatal to the subsequent keeping of lawns in good order.

Having selected and marked-out the site for a lawn, the first step will be to ascertain the character of its natural soil. If it is of a retentive nature it will require draining, or the water will accumulate from heavy rains and remain on the surface for a considerable time. This can be avoided by laying drains, the depth of which must be regulated by the fall to be obtained. Lay common drain pipes at a sufficient depth to allow of a covering of brick-rubbish, clinkers, or burnt clay being placed over them, which will allow the rains to penetrate away as they fall, but on very light ground drains are almost unnecessary.

The process of levelling a site for a lawn is very simple and can be expeditiously done with the aid of a common spirit level and a quantity of stakes, but in very few cases is it desirable that lawns should be absolutely flat and level. The surface can be made smooth and even, while the ground in itself may be of a natural slope; raised mounds and corresponding hollows can be retained in accordance with the taste of the operator and the facilities at command, without leaving the surface either in holes or inequalities. When the surface-line has been determined take off all the highest ground and convey it to the hollow places which require filling up. This will facilitate the work of levelling during digging or trenching, which must be done all over to the depth of 18 inches, and should the ground be very light it would be advisable to trench even deeper. This increases the labour and expense, but it is of the greatest importance, and the benefit derived thereby during hot weather and prolonged droughts will more than repay the first outlay. The digging or trenching being completed the plot should be further levelled and made firm with a heavy roller. The more rolling it receives the sooner will it settle sufficiently to allow either turf to be relaid or grass seeds to be sown. Should the natural ground be very stony it will be an advantage to procure better soil and spread it all over the surface to the depth of 2 or 3 inches, raking it level with an iron-toothed rake.

After the ground has been thoroughly cleaned and become consolidated, it is then ready to be either laid down with turf cut from some fine pasture land, which will at once give a complete sward, or grass seeds of the proper mixtures which are supplied by the leading seedsmen. The laying of turf is undoubtedly the quickest way of obtaining a complete lawn, but the sowing of grass seeds is most economical at first, especially if the space intended to lay down be of a great extent. Turves for relaying are cut in lengths of 3 feet, 1 foot wide, and about an inch in thickness. As the work of cutting each turf proceeds they are rolled tight, in which position they remain until replaced in their new position. By measuring the space intended to be turved the quantity required will easily be ascertained. In the laying of turf have a quantity of planks at hand to convey them on, which will prevent the wheelbarrows from injuring the newly levelled ground. A garden line stretched tight at given intervals will point out any irregularities made by this or any other cause. Place the turves close together and well beat them with a turf beater; this helps to consolidate the whole, and afterwards the lawn should be well swept and often rolled.

The grass edges on the sides of walks should be cut with an edging-knife, and should never exceed 1 inch or 1½ inch in height, and be kept uniform throughout. A deep raw edge is very objectionable, while a low and uniform edge imparts a pleasing effect to both walks and borders.

Sowing Seeds.—The preparation of the soil for laying down with seeds is, as we have before pointed out, precisely the same as for laying the turf. Before sowing the seed the ground should be evenly raked all over, and after sowing has been accomplished it

should be again rolled and a watch kept to prevent the sparrows and other small birds from taking the seeds away before they have had time to germinate. February, March, or April are suitable months for sowing lawns. After the grass has attained the height of a few inches it will be necessary to run over it frequently with a scythe until the lawn is become fairly established. In all cases where it is found desirable to sow grass the verges should be first laid with established turf, which impart a finish to the walks and give the shape and firmness to the lawn.

Renovating Old Lawns.—After a time lawns become mossy, which weakens the grass, and sometimes weeds, such as daisies, dandelions, and plantains, will make their appearance. Such weeds may be easily eradicated by a weeding-hook; it is somewhat tedious work, but if persevered in is effectual. But for mossy lawns it is a good time from now to the end of March to rake them frequently with an iron rake in order to loosen the moss, and the more that can be removed the better. Then spread regularly all over the surface some well-decayed manure, in which cow dung forms the greatest part. Let this lie until the first week in April, when it should be raked, sowing all over the lawn Suckling Clover (*Trifolium minus*) at the rate of 12 lbs. to the acre, and if the soil is light a pound of Bird's-foot Trefoil (*Lotus corniculatus minor*) may be added. After sowing the seed rake lightly to cover it, and frequently roll with a heavy roller, and the Clover seed will soon make its appearance as thick as Cress.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE ground intended for Onions, Carrots, and other root crops should be made ready whenever the weather permits. Ground that was well manured and trenched in the autumn will only require forking over when in a suitable condition, which is when it does not clog. The forking will tend to bring the surface into proper tilth for sowing by disintegrating and loosening, which ensures its more speedy drying. Before sowing the seeds of root crops we like to give the ground a dressing of two parts of quicklime and a part each of salt, soot, and wood ashes mixed and applied broadcast at the rate of half a bushel per rod (80½ square yards), pointing it in lightly. Roots are not infrequently a succeeding crop to Celery, in which case it is preferable to trench the ground, throwing the manured parts equally through the soil, not applying any fresh manure, especially for Carrots: but for Onions, if the ground is not in good heart, well-decayed manure may be applied. Onions prefer a firm soil; indeed for those the ground can hardly be made too solid, being well trodden down before the drills are made, which should be 12 inches apart. Parsnips and Carrots do better with the soil rather firm, as they do not run to top so much when the soil is firm as when it is loose. Potatoes of the early kinds, such as Veitch's Ashleaf and Myatt's Prolific, may in light soils be planted on a south border. A row planted 1 foot from a south wall will come in early, and in such positions are readily protected from frost. Plant the tubers 6 inches deep, the rows being 2 feet apart and the sets 12 to 15 inches asunder. Sow successional crops of Peas and Broad Beans, which may now be sown in the open quarters. Lettuces wintered in frames or in seed beds in a warm situation may be transplanted now in the rich soil of a warm border. Plant Onions for seed and for affording scallions.

Forcing Department.—Maintain the supply of Asparagus, Rhubarb, and Seakale by the introduction of fresh roots, also salading such as Endive and Chicory. Sow Capsicums in a temperature of 60° to 65°, and prick off Celery in boxes of rich soil, keeping near the glass. Celery may also be pricked out in frames. Cauliflowers and Lettuces remove the lights from whenever the temperature outside is over 40°, ventilating freely at 35° externally, closing only when frosty. Carrots, Radishes, and Potatoes ventilate freely when the weather is fine, and continue to plant Potatoes in frames or pits. Sow Mustard and Cress frequently to maintain the needful supply.

Dwarf Kidney Beans.—After this period of the year we prefer growing the successional crops in beds formed either of fermenting material on which frames are placed, or in pits heated by hot water. Ten inches of good soil pressed rather firmly is provided, and drills are drawn about 8 inches deep and 15 inches apart. The seeds are placed in the drills 6 inches asunder, and pressed in the soil to a depth of 1½ inch. It is then ridge and furrow, the seed being in the latter; but as the plants grow the ridges are made level by earthing-up the plants. The surface of the bed is 2 feet to 2 feet 6 inches from the glass. The sorts named last week for pots are suitable, also Canadian Wonder, which has the finest pods of any, but it is tall-growing and should have the rows 2 feet apart. Crops grown in beds are very much more productive and longer-continued than those grown in pots, and are had also with considerably lessened labour.

HARDY FRUIT GARDEN.

The planting of fruit trees of whatever kind, whether against walls or in the open, should be completed as soon as possible. It is often advisable to replace undesirable kinds of Apples and Pears by grafting preferably to removing full-sized specimens, and

replacing them by young trees; indeed where the trees of any kind do not succeed it is desirable to head them down and graft them with such kinds as afford good returns. A healthy tree grafted will in two or three years make considerably more progress than a young tree planted at the same time. The result of grafting such healthy old stocks is generally very satisfactory. These remarks apply more particularly to standard trees. Scions of the required kinds where grafting is contemplated may be taken off and the ends inserted in the ground in a shady situation, which will retard the growth until the sap in the stocks is active. The scions should be the well-ripened growths of last year. Let all pruning, dressing of the trees for insects, nailing or tying, be concluded forthwith. Any trees infested with mussel scale or American blight may be dressed with paraffin oil, keeping it off any swollen buds.

PLEASURE GROUNDS.

Push forward all alterations, especially those necessitating removing and relaying turf and the planting or removal of deciduous trees and shrubs. Work of this kind put off until spring entails much more labour besides not being so well done, as if the spring be dry the shrubs, &c., cause considerable trouble in watering them before they are established. Lawns that have quite as much moss as grass, which may arise from a poor shallow soil or exhaustion from frequent cutting with the machine—tantamount to taking a hay crop several times in a season, will be improved by a good top-dressing. Vegetable refuse reduced to soil, mixed with a sixth part of quicklime and a tenth of wood ashes with a twentieth part soot, is an excellent compost, the whole being well mixed and sifted through a half-inch sieve before application. A moderate is preferable to a heavy dressing. Twelve cartloads are a very good dressing per acre. The lime and wood ashes will destroy the moss, which will give place to fine grass, soot being a powerful fertiliser, giving a deep green colour to the grass which is so desirable. The dressing should be spread evenly, leaving the rains to wash it in. Nothing freshens a lawn so much at the dull season as sweeping and rolling, which should be practised whenever opportunity offers. Walks, too, keep bright and clean, rolling them well especially after frost, and if dirty a sprinkling of clean gravel may be given. The pruning of deciduous trees and shrubs should be completed without delay. These trees are often much neglected by being allowed to grow into ill-shapen specimens and irregular outlines; a timely attention to removing such branches as cross each other, cutting out old stunted growth and cutting back irregularities, will rectify this. The work must, however, be done judiciously. Trees and shrubs recently removed are the better if mulched over the roots with decayed leaves and any vegetable refuse that is in a partially decayed state; it facilitates the formation of roots by maintaining a more uniform moisture. Secure the stems thoroughly to stakes, nothing being so fatal to the trees rooting as allowing the heads to be blown to and fro by winds.

FRUIT HOUSES.

Vines.—Pay strict attention to stopping the shoots in the early houses. Every shoot allowed to grow a foot and then reduced to a few inches only first promotes and then suddenly retards root-action, giving a check to the Vines, which is not an unfrequent cause of shanking at a later period. Avoid, therefore, such a practice, but rather stop the growths frequently, which is equally necessary to prevent overcrowding of the foliage. Tying down the shoots should also be frequently and carefully attended to, as when they are allowed to grow considerably before they are secured to the wires there is much danger of their snapping off at their junction with the old wood. Proceed with thinning in the earliest houses. No well-defined rule can be laid down for thinning Grapes, as the different varieties vary much in form and size of bunch and berry. Young and very vigorous Vines produce loose bunches, which require very little thinning but considerable tying-out of the shoulders, and old Vines give close compact bunches, necessitating rather severe thinning to secure large berries. All shy-setting Grapes, such as Muscats, require great caution in thinning. It must be done very sparingly at first until it is seen by the fertilised berries taking the lead which to remove. Avoid cold draughts, which are more certain to cause rust than other too-often-accused causes, such as handling, rubbing with the hair, steam from water arising from heated surfaces, and sulphuring hot-water pipes, which are all best avoided; but rust we find usually follows the admission of cold dry air to the viney. Disbud and tie down in the succession house. The Vines started early in January will be in a forward state, especially Hamburgs, but if there are Muscats in the house they will only be showing fruit. Hamburgs not infrequently produce tendrils only, and Muscats become "deaf" and curl up. This arises mostly from imperfectly ripened wood and sometimes from a too low temperature; advance, therefore, the temperature to 60° at night, falling to 55° in the morning of severe weather, with 55° to 70° by day, increasing to 80° from sun heat, maintaining a moist genial atmosphere, ventilating moderately in bright but cold weather. If any Vines are breaking irregularly, or at the top only, depress the rods until the whole of the shoots are 2 inches long, and then secure the rods in their proper positions. The

fruit should be cleared from late houses without delay, pruning and dressing the Vines as previously advised, affording them a season of rest by keeping the house as cool as possible.

Peaches and Nectarines.—Attention must be paid to tying-in the shoots as they advance and to syringing, so as to keep red spider in check. Weak liquid manure may be given to the roots after the fruit is the size of small marbles. Take care that the roots do not suffer by want of moisture, as they too often do from the surface of the soil looking moist from syringing whilst the soil below is too dry. The night temperature may now be 65° to 60°, falling to 55° in the morning in severe weather, and 70° to 75° by day with sun. Proceed with disbudding in the second house, and in the case of the fruit setting very thickly remove some of the smaller, badly placed, and that on the under side of the branches. Syringe morning and evening after the fruit is set to clear away the remnants of the blossom and to keep down insects. If aphid appear fumigate with tobacco moderately, having the foliage dry, but the floors, &c., well damped. Discontinue syringing in the house started early in the month when the blossoms are expanding, sprinkling the floors, &c., in bright weather morning and afternoon, leaving a little air on constantly. Temperature 55° to 50° at night, or 5° lower in the morning in severe weather, and 55° by day from fire heat, advancing to 65° with sun and air.

Figs.—Those in pots started early will require syringing twice daily and due watering at the roots, which must not be allowed to lack moisture. Admit air at 70°, advancing to 80°, the night temperature being 60°, 5° lower in the morning in severe weather, and 65° by day from fire heat. Those planted out will be making growths, which may be pinched if strong at the fifth or sixth leaf, but it is not necessary to do this unless very vigorous. The terminal shoots may be trained in their full length, and the shoots which issue from the base of the terminals pinch at the fourth or fifth leaf. Avoid overcrowding by judiciously thinning the shoots.

Melons.—The plants will now be growing apace, and will be ready to plant out shortly. Early Melons do well in a low span-roofed house of about 10 feet internal width, which admits of a 3-feet pathway and a bed on each side. Two rows of hot-water pipes will be required for each bed for bottom heat, and one running all round the house by the front walls, with one on each side of the path for top heat. The pipes in the bed should be covered with brickbats or rubble 6 inches deep—unless they be enclosed in a chamber, when it is not necessary to employ rubble to surround and cover the pipes—and over the rubble place a layer of turves, grass side downwards, and then the soil, which should consist of mellow and rather heavy turfy loam, and be raised in hillocks or ridges 18 inches to 2 feet wide and 8 inches deep, and well rammed down. Keep the plants near the glass, stopping the shoots when they have grown about two-thirds the extent of the allotted space. Bottom heat 80° to 85°, top heat 70° to 75° by day, rising to 85° with sun and moderate ventilation, and 70° to 65° at night. As slugs, &c., are not infrequently brought in with the soil, draw a circle around the stems with soot and lime, both in a dry state. It will not only serve to keep depredatory vermin at bay, but will absorb moisture from the stem and prevent decay at the collar. Make up a bed of well-sweetened dung and leaves preparatory to planting in early March, keeping the plants intended for that purpose near the glass and shifted into larger pots or top-dressed, as inactive roots rarely take to fresh soil freely.

PLANT HOUSES.

Greenhouse.—Young stock of hardwooded plants, such as *Boronia serrulata*, *Pimeleas*, *Epacris*, *Gompholobium*, *Correas*, &c., should be potted so soon as their roots become active. Good fibrous peat is the best material, with an admixture of about a sixth of silver sand. The best peat for these plants is that which contains but little sand, being of a richer kind than the sandy peat, which is more suited to the hardwooded Heaths. In potting merely remove the crocks and loosen the sides of the ball slightly. The roots must not be reduced, and any that are very much pot-bound should only have a small shift; healthy plants may have a shift of 3 to 4 inches. Drain the pots well and ram the soil with a stick very firm, and keep the neck of the plants level with the rim of the pot and sloping from it to the sides, where it should be about an inch lower than the rim. See that the ball is thoroughly moist before potting, watering carefully for a time after potting. Any large plants in small pots may now be shifted into larger, especially such as *Eriostemon*, *Hedera*, *Leschenaultia*, &c. They will flower better and the operation is more safe than when deferred until after flowering.

Camellias, if the weather be bright and the roof is not partially shaded by climbers, will after this require shade if the bloom be intended to be of some duration and the colour good. Slight shade only is necessary. *C. Bealii* is perhaps the best late red, and *C. candidissima* the best late white; but we have *fimbriata* and *alba plena* until the end of April. The plants should have copious supplies of water, and a damper atmosphere is desirable, as the increased sun heat dries the atmosphere, causing short duration of bloom, and not infrequently a dropping bud. Early-flowered plants may be encouraged to grow by placing them in a moister atmosphere and temperature of 55° at night, rising 10° to

15°, shading from bright sun. There are few plants that bear heading down so well as *Camellias*. Any overgrown or straggling plants may be cut hard back, and if kept moist and in an increased temperature will break freely. They will not, however, flower well next winter, therefore a portion of the plants only at a time should be operated on. Any straggling strong growths on vigorous plants may be shortened back, in order to keep the plants presentable in form.

Epacris going out of flower, also winter-flowering Heaths, should have the flowers, or rather the seed-pods, picked off. Plants of these intended for early flowering may be kept rather dry for a few days, and then be cut back and placed in gentle heat to encourage growth. *Vallotas* very much pot-bound may have a shift into larger pots or have the bulbs divided. They do well in turfy loam with a little well-decayed manure, and are best under rather than overpotted. They require a light airy situation.

Pelargoniums of the Show class will, as the pots fill with roots, require more water; it must not, however, be excessive, which promotes the "spot," while if under-watered the foliage turns yellow. Fancy varieties must be carefully watered; they do not as a rule require so much water as the stronger-growing class. See to regulating the shoots and stopping for successional bloom, keeping the plants near the glass and well ventilated, insects, particularly aphid, being promptly met by fumigation.

Shift into larger pots *Calceolarias* that are now growing freely, and those showing for bloom assist with weak liquid manure. Vigorous plants not showing flower may have a shift from a 5-inch pot to an 8 or 10-inch; but plants in 7-inch pots are more useful for decorative purposes. Weak liquid manure will materially assist *Zonal Pelargoniums* having the pots filled with roots and advanced for flowering, also those in a flowering state, also *Cinerarias*, *Primulas*, *Cyclamens*, &c. Sow *Cyclamen* seed in brick moist heat, also *Cinerarias* for early winter flowering.

TO CORRESPONDENTS.

ERICA VAGANS (*Richmond*).—You cannot do better than pot your plant in a compost of good fibry peat (not black bog nor spongy peat) and a liberal admixture of clean silver sand. Be careful that your plant is neither overwet nor overdry at the time of potting. Drain the pot well by placing in it an inch or two of crocks, on which place some clean fibre, which can be shaken from the peat, to prevent the particles of soil choking the drainage. Pot very firmly, not filling the pot too full of soil, but leave space to hold water sufficient to penetrate the whole mass of soil. When you apply water let it be copiously, but do not give any until the soil is sufficiently dry to crumble when pressed with the fingers; if it is pesty the plant will not require water. Firm potting and careful watering are important points to be attended to. This *Erica* is a native of the heaths of Cornwall.

PRIMULAS (*W. W. B.*).—The rosy purple variety is extremely fine, one of the best we have seen. The whites are pure, but slightly deficient in substance. The carmine or pale scarlet variety is very distinct on account of its dark foliage, which is of the same colour as that of *Dell's Best*; the flowers are also good. By judicious fertilisation you will establish a strain of considerable value.

GOLDEN CHICKWEED (*G. R.*).—Apply to the leading London florists. Any of them could obtain it.

GASLIGHT IN CONSERVATORY (*G. R.*).—If the plan you mention conveys through a tube all the fumes from the burning gas into the open air outside, it will not injure the plants.

OUTSIDE BLINDS (*R. Hyslop*).—Light canvas will suit for making outside blinds for your conservatory. For affording a slight shade tiffany is suitable, but is not stout enough to be attached to a roller to be moved up and down frequently. The "Exotic Fern Manual" is not being printed.

CUCUMBER AND MELON PIT (*York*).—Full directions are in our "Garden Manual," price 1s. 6d.

HEATING A SMALL STOVE (*A Subscriber*).—Your little stove, containing some 700 cubic feet of air, should have 35 feet of 4-inch piping, or say three lengths of 11 feet, to enable you to keep a winter temperature of 70° to 80° with ease and economy. This temperature might be maintained with two lengths of piping, but not without much risk in severe weather, for such small glazed structures are necessarily more subject to external influences than large houses. A liberal amount of piping involves an extra outlay in the first instance, but as certainly points to subsequent economy of fuel. A flow and return pipe through or rather under the bed will afford ample bottom heat. Let your boiler be in a shed at the back of the stove close to the partition, so that you may take a pipe from it into the intermediate house, where a couple of lengths—just a flow and return—will be quite sufficient. You will require three valves, all of which should be in the stoker's and not in the houses: one to control the stove bottom heat, another for the upper pipes, and one for the intermediate house. These valves to be put on the flow pipes as near the boiler as possible in order to economise heat.

ALTERNANTHERAS (*M. T. L.*).—Any florist could supply you with them now.

LILIUM AURATUM (*H. Roose*).—The vermin on the bulbs you describe are wireworms. We should take up the bulbs, clear away all the soil from them, and replant them in soil not infested by wireworms. To promote the flowering of *Epiphyllum* the plants require to make strong growth during the summer by being potted in good soil and watered liberally, withholding the water in September and keeping the plants comparatively dry for two months.

GERMINATING POWER OF SEED (*C. S.*).—Of the vegetable seeds which you bought four years ago, *Pans* may be depended upon to grow fairly well, but none of the varieties of seeds will give plants equal in vigour to those from new seed. Radish will grow, and so will Spinach, Capsicum, Lettuce, Cucumber, Melon, Tomato, Cauliflower, Broccoli, Cabbage, Savoy, Brussels

Sprouts, and all other sorts of winter Greens, Mustard and Cress, Endive, Beet, Celery, Watercress, Ramplon, Fennel, Chicory, Corn Salad, Basil, Artichoke, Broad Beans, Carrot, Vegetable Marrow. Other vegetables are doubtful, so are flower seeds, and in the vegetables selected a broad margin must be allowed for failures and weakly plants. To avoid failure and disappointment sow immediately a pinch of each kind of seed in separate pots, which place upon a brisk hotbed, and all seed still retaining vitality will germinate in a few days.

HOT-WATER PIPING—GENERAL HINTS FOR AN AMATEUR'S VINERY (W. E. B.).—As we do not advise early forcing or a high winter temperature for such a small house, a flow and return pipe along both sides and one end of the house will suffice. Your Black Hamburgh will answer admirably for the roof, and a couple of Camellias will suffice as permanent occupants for the back wall, with four more to be kept in pots and trained upon the wall till its space is required for the permanent plants. Here are six good sorts—Zoraida Vanzi, Princess Mary, Fimbriata, Lavinia Maggi, Lavinia Maggi rosea, Elvira Bianchini. Your zonal Pelargoniums will make the house gay throughout winter, and you should have a few Cinerarias and Primula sinensis raised from seed sown in March, three or four Cyclamen persicum, at least one of the large white Carnation Souvenir de la Malmaison, and three or four Azaleas, such as Queen of Roses, Roi d'Hollande, Eveline, and A. Borsig. Tomatoes may be grown very well in pots in such a house for a year or two, but after the interior becomes shaded by the Grape Vine they will not answer so well. Sow the seed in March, pot the plants singly, and repot them as required, employing plenty of drainage and a rough rich soil, for the Tomato requires a generous diet, and can hardly be overwatered after the pots become full of roots. After the fruit is set and begins swelling substitute liquid manure for water entirely. The fruiting pots should be from 8 inches to a foot in diameter. One plant only in a pot.

SEEDS FROM THE NEILGHERRY HILLS (A Very Old Subscriber).—We cannot spare the space which would be required. Consult "The Cottage Gardener's Dictionary."

POULTRY TRESPASSING (S. F.).—You must not poison nor shoot the poultry. Your legal mode of proceeding is to give your neighbour a written notice that if his poultry trespass on your garden you will sue him for the damage they do. If they continue to trespass proceed against him in the County Court.

INSECT (T. S., Exeter).—It is the common garden mite, *Acarus hortensis*.

NAMES OF FRUITS (W. H. Ashwin).—5, Cluster Golden Pippin.

NAME OF PLANT (J. Atfield).—It is *Lonicera fragrantissima*. The Savoy sent is extremely curious, and will be submitted to the Scientific Committee of the Royal Horticultural Society.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE CULTIVATION OF BARLEY.

THE price of wheat having taken a lower range for some years past, and the strong probability of its being imported as one of the principal products of other countries, barley is now becoming one of the chief agricultural products of the kingdom, chiefly on account of the favourable soil and climate of a large portion of this country; and it is also very encouraging to the farmer, in consequence of the high price of malting barley, to study how to obtain a first-rate sample where there is so large a difference as 12s. or 15s. per quarter between malting and grinding samples.

Barley may certainly be considered as one of our most valuable grain products, not only on account of its supplying an useful and nutritious beverage to a large portion of our population, but also as being next to wheat the most valuable of the farmers' grain produce upon a considerable portion of the land of this kingdom; but the description of land best suited to it is that which consists chiefly of a sandy, chalky, or gravelly composition. All such light soils are recognised by farmers in general as kind barley land; nevertheless, we have found that it is cultivated upon almost every description of land in the country with varying results, though to grow it in perfection upon different soils a variety of modes of preparing the land is necessary, and also such rotations of cropping as are proved to be best adapted to the soil, having due regard to situation and aspect. In preparing any land for barley we should always keep one object in view, that of obtaining a full crop, as it must be recollected that many of the charges upon the land—such as rent, tithes, and poor rates—are the same whether we obtain a good or bad crop, and it too often happens that farmers fall short in their preparation for a full crop more from a deficiency in the outlay of capital and liberality in cultivation than from any want of knowledge of their business. Whenever the barley crop is attempted upon land naturally wet underdraining should be thoroughly performed before the seed is sown, for barley, above all kinds of grain, delights in a dry warm soil. Due regard should also be had to remove all couch grass and weeds of every kind, as the growth of such is sure to prove

a serious drawback upon the crop, and unless the land is fresh in chalk such weeds are sure to prevail, chalk having also the favourable effect of making the soil lighter, more porous, and freer to work. It is not usual in a four-course rotation to manure for this crop in a direct manner, nor will it be found desirable that the land should be very rich or highly dressed, otherwise more straw will be produced than will be conducive to the yield of grain, inasmuch as when barley is laid or lodged there is no crop suffers so much depreciation either in quantity or quality, but more especially the latter, for instead of fetching the best price for malting purposes it will be merely fit for grinding or distilling. The only exception which can be made to the foregoing observations is in the case of many kinds of shallow, poor, dry soils, for upon such land it would be almost impossible to over-manure or dress too highly, as in the majority of seasons an overburden of straw would not be produced.

We do not advise barley being sown oftener than once in four years, which is strictly in accordance with the Norfolk or four-course rotation—viz., first year roots, second barley, third clover, fourth wheat. This system no doubt is well adapted to good barley soils, yet it would not be advisable to sow the crop oftener upon the richest and most fertile soils, as they can be, and usually are, occupied by more valuable crops, such as—first year wheat, second beans, third wheat; or the following:—first year turnips, second wheat and dreg, third clover, fourth wheat. An exception to the rule of sowing barley only once in four years has come within our knowledge in the case of parties who are in the habit upon sandy loam soil of sowing barley after potatoes, and so on alternately, and this course pays well, the barley proving generally a good crop of malting quality; but it must be remembered that this exception in barley cultivation only applies to land in the highest state of improvement, the plan adopted being to dress heavily for potatoes, and either a light dressing or no manure for the barley. As parties who have adopted this mode of culture continue it, it is fair to infer that in particular cases it answers their purpose; and although it must be regarded as a divergence from the ordinary rules of cultivation, and not often tolerated in farm leases, yet to those who have full control of the land on a home farm it may be resorted to as equally justifiable as it is to sow barley after wheat, which upon some soils where it does not grow kindly after root crops is almost the only place in the rotation where it can be profitably introduced. The rotation alluded to is—first year turnips, second wheat, third barley, fourth clover. The practice for a long period has been very general to sow barley after turnips fed off by sheep upon all dry soils in almost every county in England, but we must observe that in our own management, and also in large districts of loamy soils that have come under our notice, barley after turnips fed off on the land is anything but a remunerative crop, as it grows very irregularly, some parts being very luxuriant, and often lodged in the grass state before coming into ear, other parts being very deficient, owing to the heading of the stock in wet weather. But it may be asked, If the barley crop suffers so much from this system upon the mixed or varying soils, why pursue it? The usual reply is that sheep must be kept, they being the rent-payers on the farm; but in many cases this idea is giving place to a plan whereby a portion of the roots are pulled away for cattle at the homestead and supplying the sheep with cake or corn whilst feeding off the roots, but the general effect of either system of feeding roots on the land is to render the crop of barley a very precarious one. Under particular circumstances, however, which render it desirable to continue the barley crop, a counteraction of high tillage will be found in the following plan:—Plough once only after feeding off the roots, but plough deep enough to bring up a little fresh earth, and sow a reduced quantity of seed at the earliest period the land can be made to work freely. It is a successful method of cultivating for barley upon good dry loams after a crop of potatoes, the rotation being—first year potatoes, second barley, third clover, fourth wheat, and this is certainly one of the best preparations upon loamy and mixed soils. It is, however, desirable that the

land should be cultivated by steam power or otherwise in the autumn after the wheat crop in preparation for potatoes, particularly as the early sorts are most successful in avoiding the disease. This course of cropping will be found especially advantageous upon all land subject to couch grass, or more than usually liable to the growth of weeds. Plenty of opportunities are offered for cleaning and preparing the ground after the potato crop is off, and the winter fallow succeeding reduces the land into a remarkably kind state to receive the seed at a very early period, which is so essential in obtaining a malting sample.

It is scarcely necessary to be named, were it not that many inconsistencies in cultivation are continued and considered by numerous farmers essential to the success of the system of preparing the land after root-feeding, in which we consider they are not borne out. For instance, in preparing the land it is a common practice to plough two or three times, with sundry harrowings and rollings after the roots are fed off, which we consider cannot be required for the success of the crop; for although the treading of the sheep in feeding off turns upon all light and dry soils may be deemed essential in consolidating the land and enabling it to retain the manure and to withstand the drought of summer, yet it cannot be said to require repeated ploughings, &c., the effect of which is calculated to increase the expense of tillage, delay the time of sowing, and in a dry season the barley may only partially vegetate, and the produce in consequence will be deficient, being also edge-grown and quite unfit for malting. The clover seeds when sown amongst the barley often do not vegetate and suffer from the same cause; it will, moreover, be found in a favourable season too encouraging to the growth of straw, the land being already in a sufficiently fertile state, produced by the usual cultivation for turnips. Instead of these repeated ploughings we have found it the best plan to wait until the land is sufficiently dry to work freely, then plough once, and should the weather be inclined to be harsh and dry the land should be worked immediately after ploughing and not later than the following day, otherwise light land will become too dry, and strong soils will harden and be rendered incapable of being reduced to a fine tilth so essential in the cultivation of barley.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—There is no more busy time for the horses than the present during the whole year. Ploughing for beans, peas, oats, and barley will now be going on, also drilling and harrowing in due course. The nature and condition of the soil will influence to a certain extent which crop shall be first put in. Long days—that is, working the horses until nearly dark, is sometimes necessary when the work is much in arrear; but we find the teammen sometimes objecting to work with the horses beyond the usual hours of labour. In order to meet this objection we often take a labourer to do some of the work properly belonging to the teammen, such as cutting-out hay, bringing in straw to stables for litter, preparing swedes or carrots, &c., for when this work is done for them we do not often find the teammen unwilling to continue the horse labour for some hours beyond the customary time. But in order to meet this demand of extra labour from the horses they should be kept in high condition, and more especially should they have a moderate allowance of roots, besides corn and chaff; and in some seasons extra labour contributed by the horses proves exceedingly valuable, and, in fact, is the only means of bringing up arrears of work.

Hand Labour.—Hedging, banking, &c., being now nearly concluded, grubbing may now be commenced; and it is very desirable on some farms that various fences should be removed, as it is not well to trust the sheep without hurdles in feeding either in summer or winter time, and many changes occur which make it advantageous to grub up fences, such as draining, for when the land is properly drained the ditches may be drained also, and the banks thrown down. We have on our own occupation grubbed some miles of fencing, gaining the land, saving expense of trimming hedges, saving also the repairs of gates and pales, and being able to lay the land out for ploughing in long reaches without the usual short work, and at the same time saving long distances for cartage of dung, and also corn and hay at harvest, without being obliged to take a circuitous route to reach the gateways between fields. Men should now be employed, if not already done, in preparing ground to receive cabbage seeds, &c., and if it is not provided for in a large garden, or in a garden attached to the estate to which the home farm belongs, by the land being already dug and tilled ready for the seed, it should be done off-hand, the sooner the better, as we do not like to defer the sowing seed to raise plants for setting out on the farm after this time, because it often happens that the first sunny weather which occurs brings out the turnip fly, which carries off the young plants, and an accident or mistake of this sort cannot always be rectified in the same season, and necessitates the purchase of plants instead of growing them. It is also essential that the land should be well prepared, and if done in the previous autumn so much the better; but it sometimes occurs that, however well prepared the ground

may be, the plants will not come on healthy and sound at root if the land is deficient in chalk or lime, and if plants are grown under such circumstances they are sure never to thrive when planted out, for many of them will club at root; therefore before sowing the seed let it be well understood whether the ground is fresh in chalk, if not chalk or lime at the time of seeding is the only safe remedy to obtain healthy plants. The seeds may be drilled with the small hand drill at about 14 inches apart, and the sorts of cabbage we prefer are the Ox-heart, the Champion Cattle cabbage, and the Drumhead savy; they give an excellent succession for cattle and sheep feeding. The Ox-heart we find the best early cabbage for cattle, as they come very quickly of good size and grow without many outside and wasteful leaves. Women's labour will still be required in various directions on the farm; in fact we always find that it is well to look forward and find employment for them regularly, seeing that so much of the lightest farm work at present wages to men cannot be profitably done by them, nor the farm and premises be kept tidy and decent without being very costly.

SEASONABLE AGRICULTURAL NOTES.

THE preparation of such land for barley as I named on page 117 is very much economised by not delaying a day after the land will carry the horses. Presuming that some attempt has been made to sow it with wheat in the autumn it will have been harrowed down; if so, so much the worse. How and when the land is fit for the horses' feet is a very nice point to decide. Some say he succeeds the best who keeps off strong wet land the longest. From years of experience I find a week of dry weather is sufficient when the season is well advanced to make the difference between a damp condition of plastic clay and a free and friable mould. When the soil will bear treading and will then crumble in the hand, then at once is the time to plough such land over again, presuming its previous crop had been anything but clover. If the latter, waiting yet awhile and then employing the chiseled-tooth harrow, is found in practice better than ploughing. Good stout young active horses, good ploughs, and good ploughmen are the desiderata for such land.

When land is well done and well worked it is half way to a good crop. The ploughing of such land must not be delayed a day. The frosts which follow soon put all right. The great secret for barley is a friable mould underneath, never mind a few rough clods on the surface. After the frost and when the land is again dry enough the chiseled-tooth harrow on wheels—that made by Ashton of Horncastle—is the best, as it can be regulated to a proper depth, for this purpose. The seeding will go on in its season; we are now only anticipating that, though short, distant time.

Depend upon it to carry on farming successfully now all things must be of the best and most approved principles—ploughs, harrows, drills, horse hoes, scarifiers, &c., accomplish work now in such a manner that would astonish our fathers. At all events, if the improvements of the past twenty-five years have not prevented farming from collapsing altogether in this country, they have to some extent been the means of maintaining the balance between the farmer's income and his serious losses of the same years. Successful farming consists in adopting all the available means which observation has placed at our disposal for increasing production and lessening the cost. The proper thing at the proper time is as essential as the showers of April and sunshine of May. The chain must be perfect; no patchwork or delay. The simple matter of ploughing being neglected at its proper time, began of when too late, is at the least the very reverse at which I wish to aim at. Nothing must be left to chance. A master's eye, his presence, and daily superintendence of the different avocations of the farm works wonders.

There is yet another place where barley is often well and profitably grown. In our four-field course, on land in good tilth, free from twitch, and in good heart, a crop of barley is taken after wheat, which is followed by turnips. In this case we will suppose it is either loam or good light land. Nothing more is requisite for such than crossing with the plough during February. Some people say it is best not crossed with the plough, but by either drag, cultivator, or wheeled harrow. Such a "cross crop," as it is called, would be all the better for having a dressing at sowing time of 1 cwt. of good Peruvian guano and 1 cwt. of nitrate of soda, and as seeds are not sown with this crop a cwt. or two of common agricultural salt might be added. In practice we find this crop of barley requires about one peck of seed less per acre than on heavy land. The strong land ought to be sown when it will work, but the seeding of it should be thicker than on good barley soils. As seed time arrives I will state when we in Lincolnshire begin, and the different quantities we find the most suitable for the varying soils of our county. Another item of great import is the change of seed from different climates. The different varieties also should engage the attention of the farmer more than they have hitherto done. The old Yorkshire Long Ear and Thanet barleys were popular a quarter of a century ago, but they have disappeared, and perhaps Hallet's Pedigree now rules the day.

All points considered it is perhaps the best for all good barley soils, but more of this hereafter.—*RUSTICUS, Lincoln.*

LANGSHAN FOWLS.

THE *Journal of Horticulture* of January 24th contains a notice of the Jardin d'Acclimation du Bois de Boulogne. The writer amongst other places speaks of a visit to the poulaillerie, where he saw a Langshan cock which he admired but could not tell whence it came. I am in a position to state that the Langshans in the gardens were procured from the yards of the late Major Croad in 1876, and that their importer has been awarded the Society's medal for their introduction into France. I am glad to hear the Langshan bears confinement well, for it is a most lovely bird and loves a free range. If your correspondent will be at the pains to visit some of the yards where the Langshan is kept in England I am sure he will have the gratification of seeing some magnificent specimens of this useful breed. Classes are now being arranged for them at the various shows, and I may add Mr. Buchan of Southampton lately won the first prize at Dorchester with a fine pair of birds.—*A. C. CROAD, Manor House, Durrington, Worthing.*

THE PRESENT ASPECT OF THE PIGEON FANCY.

I READ last week in "our Journal" a very striking and interesting article on "The Present Aspect of Poultry Showing," by "C." I must also say something as to the Pigeon-showing and Pigeon fancy of the present time. First let me remark, and with much pleasure, that I do not believe there ever were in England so many good fancy Pigeons as at the present time. Where twenty years ago there were a dozen, now there are a hundred. Then go further back—another ten years. Why, there are now a hundred good Pigeons where thirty years ago there were but five—if even five. This increase in good birds has, I fully allow, been caused very much by shows. Here is the good work they have done: they have strengthened or created a taste, and created also a trade. Then also the varieties of the birds are now known very generally. One no longer hears absurdly ignorant remarks at shows by those passing past the pens, as to what "the funny birds" are, &c. All this I willingly and gladly allow as to the past benefit of exhibitions.

At the present time the state of things in regard to Pigeon shows is this:—Although the novelty is gone, they, I think, are more attractive to ladies than poultry shows. There is no annoying crowing. They are also perfectly clean birds, and no nose, even the most delicate, is offended; also naturally they are far prettier birds, and more attractive to the casual and partly indifferent visitor or non-fancier; also their weight is little, and hence the cost of their carriage is far less than that of fowls, to say nothing of huge Geese and more huge Turkeys. All these things are in their favour; but a few exhibitors have risen, giants to all the rest, and to them as a rule the prizes have gone, hence the smaller fanciers have become discouraged. Indeed, I may exclude almost the word fancier from some great breeders and exhibitors of fancy Pigeons, who have "gone into them" as a business, just as another man goes into farming—the profit, not the fancy, being the consideration. Such great and supremely successful exhibitors have injured shows by discouraging others, although far from having injured them in another sense, for their birds have been better worth looking at than any others; still they prevent others sending their birds. Then, too, there is another reason—a painful one. The trimming, dressing-up, colouring, &c., have prevented strictly conscientious or less able makers-up of show Pigeons from exhibiting. A great deal of wrong-doing has been no doubt going on. Even books in which these tricks have been mentioned have served to deter honest people, who not unnaturally feel "what is the use of my competing in such company? my birds shall only be honestly shown, and I know that so shown they cannot win." Deceptive dealing has had an injurious effect, puffing-up birds in cheap advertisements as "of the best strains in England," "sure winners," &c., when really they were mere rubbish. I can only make one excuse for such advertisers; possibly they might not know what are really good birds, though I fear usually it is mere dishonest puffing. But if there is the deceptive seller, there is also that objectionable person the crafty-minded purchaser, who pleading youth or poverty implores you to sell him good birds at a very cheap price; or sometimes it is said "not for exhibition," and then comes the after-letter confessing that they were for exhibition, and complaining that they are not good enough. Then, too, there is the crafty-minded purchaser who sets a trap to catch some green vendor, possibly the vendor being a clergyman or a lady, and therefore supposed to be of a decided green tint. The applicant begins by stating that he wishes for "birds fit for the highest competition," giving all particulars to eyes, beak, colour, &c.; then he ends with an appeal to the supposed greenness of the seller to let him have them very cheap, as he is an ardent or a young (doubtful this!) fancier, or some other plea. Such letters vex fanciers who have

birds that have cost them a large sum of money, and who naturally and properly wish to sell them or their produce without loss.

Well, next what do I recommend as to the future? If poultry shows are not to be held in places where they were formerly, why should not Pigeons and cage birds form a show? I think this combination would be both popular and suitable. Hold poultry shows if you can, or fowls and cats, but when committees shrink any longer from venturing upon poultry I would say, Let them try Pigeons and cage birds. Why should not such a show be tried in Bristol? for hundreds, of ladies especially, keep or admire cage birds who know nothing of poultry.

In another article I shall hope to prove that, after all, shows are not absolutely essential to the maintenance and culture of fancy Pigeons. Glad should I have been if poultry and Pigeon shows could have gone on and prospered; but we must now, to a degree at least, make a change of front. I specially invite fanciers to write their opinions on this subject.—*WILTSHIRE RECTOR.*

THE POULTRY CLUB.

WE announced last week that the original members of the new Poultry Club are about to be elected. We wish the Club all success, and are sure that it may do a really good work if only fanciers in general are public-spirited enough to sink any individual crotchets or supposed interests, and to unite to rid their hobby of a certain opprobrium, which, whether justly or unjustly has—there is no denying it—begun of late to be cast upon it. For those of our readers who may not have followed the scheme from the beginning we will give a short sketch of its origin.

For some time past the system of trimming or improving birds (or call it what you may) for show purposes has certainly been on the increase. Most honourable men had often observed to us that in certain varieties it was impossible to win with birds shown in their natural state, and that so they had been obliged, in the phraseology of the day, to "follow the times," and embellish their birds in a way they did not at heart approve of. One or two flagrant cases of trimming were exposed at the Crystal Palace and elsewhere. In some of them the judges were not so eager as might have been wished to expose the fraud; in others, when they were willing to do so, they complained that committees were too short-sightedly timid to back them up, or had their schedules so badly worded as not to warrant a prize being withheld. Accounts, naturally much exaggerated, of the rogueries practised in poultry-fancying appeared in newspapers not generally devoted to such subjects, and it was at once seen by upright exhibitors that something must be done, or they might feel constrained to give up their hobby as having become a medium of fraud. Some combined action was necessary, but how to combine was the question. Our contemporary *The Live Stock Journal* invited discussion on the question, and a large number of letters appeared in his columns, most of them, as is usual in such cases, more full of righteous indignation than practical suggestions. Eventually the difficulty of a beginning was surmounted in a way we think sensible. A few fanciers above suspicion of interested motives last spring drew up a list of some fifteen names, most carefully selected as representative fanciers, to form a preliminary or organising Committee. Their chief duty was to discover how far the general feeling of poultry fanciers was in favour of attempting a club to remedy some of these abuses. It must be remembered that one or two such societies had been hurriedly started and had failed, and this had to be taken into consideration. This Committee was certainly not chargeable with any undue haste, for various circumstances, chiefly the difficulty of meeting in the summer months, retarded their labours, and no practical steps towards the formation of the Club were taken till the autumn.

Meanwhile we learn a large number of fanciers had signified their earnest desire to belong to such a society. A general meeting was held at the Crystal Palace during the show week, and the subject was discussed in its various bearings. Warnings were given by Mr. Tegetmeier and other experienced fanciers based on former failures, still those present seemed determined, as the Chairman (the Hon. and Rev. F. G. Dutton) well expressed it, to have another try. The meeting formally appointed a Committee to draw up a code of rules, almost identical with the Committee already informally appointed, and adjourned to Birmingham. There a scheme of rules drawn up with considerable care was, after much discussion and amendment, carried, as well as several resolutions. So scrupulous were the Committee about seeming a self-constituted body, although they had been regularly appointed at the Crystal Palace, that they only agreed to elect, as a safeguard, the original members, which they will do on the 26th of this month, and then resolved to retire, leaving the elected members to elect their own permanent officers and committee. So much about the constitution of the Club, which we must say seems to have been devised in a very careful and scrupulous, though perhaps in a somewhat cumbersome manner. Every precaution has been taken that the Society should be as general as possible, and unconnected with any newspaper or party, so that if ever it should become cliqueish fanciers in general will only have themselves to blame for it. All the members who subscribe

a guinea a-year will have a vote in the election of its officers and committee, who in turn will elect future members, while those who subscribe but 5s. will have the general privilege of members but not this vote.

We now come to the important part—viz., the objects and action of the Club when fully constituted. We confess that we see considerable difficulties in store for it, partially from its objects being misunderstood and partially from the great tact which will in the nature of things be necessary to carry them out. It is no business of ours to instruct its future executive, still we may with propriety point out one or two lines which we think it may with advantage take, and indicate the difficulties of which it must steer clear.

1. Trimming is one of the dishonourable practices which it must combat, and the question at once comes in, "What is trimming?" Well, the dubbing of Game cocks has always been allowed, is recognised by all judges, and (*pace* the Society for the Prevention of Cruelty to Animals) has a humane object. This we take for granted will be allowed. Then it has long been considered legitimate to shave the faces of Spanish. This we think an objectionable practice, and as novices were great losers by it; still our best judges sometimes disqualify Spanish as "over-trimmed," and thereby implicitly sanction some trimming. This will be a question, How far may any improvement of this kind be looked upon as a legitimate embellishment like the grooming of a horse and thinning its mane? Polish again have, we understand, the front of their tufts frequently pulled out. This we consider cruel and should vote against it. Hamburg cocks have their combs carved about. No sort of defence can be urged for this practice, and birds with gross hereditary faults may so be palmed off upon an ignoramus as perfect specimens. However, the whole matter will doubtless be discussed with the greatest and most honourable authorities on each breed, and the opinions of the most experienced judges would of course be asked as to where the line can be best and most effectually drawn, while their experience will make it more easy for them to say.

2. This question being decided, there will of course follow the difficulty of carrying out the decision. Much must be left to moral influence, and we have lately been gratified by several personal assurances from some eminent exhibitors that though they had in a measure gone with the tide and permitted or practised minor embellishments of their show birds, they will now that the Club is formed scrupulously discontinue them. Assuredly the Club should in all cases back up disqualifications made by judges, but must, of course, in visiting fraud with censure, discover as far as possible how far the exhibitor is really culpable. It has often happened that an innocent person has bought a trimmed bird, shown it in ignorance and been disqualified. Every means should be taken by the Club to expose all connected with such transactions, and so to track out the original offender.

3. If such a course be fearlessly and judiciously carried out we feel certain that many committees will be only too glad to place themselves under the patronage of the Club, and so relieve themselves of some of the responsibility of exposing frauds. If they do so honest exhibitors will patronise them, and we know well that there are many breeders of first-class poultry who are only deterred from becoming exhibitors by fear of the tricks connected with exhibitions. Thus in time the Club might become a court of appeal, to which disputed points could be referred. At all events it will be able to subsidise well-managed shows and such as honourably carry out its recommendations.

4. As a Club for mutual protection there will be many ways in which it may aid its members. Nearly every fancier of standing has had some difficulties to which he has yielded from dislike as an individual to risk defeat or loss, but when, if backed up by such a body, he might have gained his rights. The extortionate charges of railway companies might be reduced, or at least brought to a more uniform and consistent tariff, if an energetically conducted and largely supported club were to hold out threats of patronising particular lines where there is an alternative. Defaulting committees too (though we trust to hear of no more such bodies) would hardly defy the action of a club as that of Portsmouth defied a succession of individuals who prosecuted. Such are some of the lines, very roughly sketched, on which we think the Club may usefully work, and we wish it all success in its honourable object.—C.

NATIONAL PERISTERONIC SOCIETY.

THE PRESIDENT'S ADDRESS.—SUBJECT: PATHOLOGY OF PIGEONS.

IN seeking a subject for my inaugural address as President of this Society, I have carefully considered the matter with the view of choosing one that would be most interesting and beneficial to the majority of the members, and for various reasons I have thought it best to adopt that of the pathology of the bird. I do not intend to detain you with a lengthy paper, nor to describe the culture of the bird—a subject that has been fully and ably laid before you on previous occasions. I may, however, mention with regard to a breed that I made my speciality for years, that during what I may call the rage for shows some years ago the

divergence of opinion was so great amongst judges and fanciers that I deemed it advisable to make known what experience had taught me as to the standard or type of Dragon Pigeon to be desired, and I published my views. These did not, however, receive any recognition so far as I am aware.

I will now proceed to explain, in as clear a manner as I am able, the causes, symptoms, and treatment of the diseases of the bird, more especially of the respiratory organs, as observed by me during the many years I possessed a large stud. I will first describe catarrh—that is, cold and sore throat. The symptoms of this affection, which is more prevalent in the autumn and moulting season than at other times, are perhaps familiar to you all, but may be defined as follows:—A chilliness will be present, as well as cough and sneezing. The mouth will be open, and a discharge of mucus of an adhesive character takes place from the nostrils, mouth, and throat, in some cases almost filling the same, especially when acute disease of the parts occur, and signs of diphtheria are displayed. As a remedy I have given the following composition:—1 drachm of cayenne pepper, 2 drachms of powdered gentian root, and $\frac{1}{2}$ drachm of grey powder, with sufficient soft soap to give it consistency. This I divide into small pills, one being given night and morning. These will be found beneficial in checked or heavy moults. A small pinch of salt, powdered nitre, or saltpetre should be administered twice a day. In the latter stages glycerine may be used with benefit, to which in bad cases a small portion of belladonna may be added. When diphtheria (which can be detected by the faecal or disagreeable smell from the parts) is present, or large external swellings take place on or about the throat, place a piece of wadding previously immersed in cold water round the throat, keeping it in its place by means of a piece of linen sewn over it. No hard food should be given at these times. Eggs boiled with milk or arrowroot rubbed through a fine sieve I would recommend, and this may be given by means of a small indiarubber bottle as used for diffusing insect powder. No attempt should be made to remove hard substances from the parts in the early stages of the attack.

I now come to bronchitis. This complaint may be recognised by the feathers of the bird being ruffled, a depressed and general uncomfortable appearance, cough, increased action of the heart and breathing, accompanied by abnormal sounds, such as wheezing, rattling in the throat, &c., which are audible at some distance. Birds suffering from this disease are frequently found moping in a corner of their loft, or, to use a homely but expressive phrase, all in a heap, and become emaciated in a few days. For treatment I would recommend one cayenne pill daily, also the careful introduction into the larynx and trachea of a soft tail feather, dipped one day in spirits of turpentine, and the next in weak salt and water. This may be continued for three or four days. I have found the following pills very beneficial in some cases:—Assa-fetida $1\frac{1}{2}$ grain, ginger 1 grain, and sulphur 1 grain, mixed with soft soap or treacle and given twice a day. Binioidide of mercury ointment in a mild form should be applied over the surface of the ribs under the wing where there is a scarcity of feathers, and repeated if necessary. Cod-liver oil capsules may afterwards be had recourse to with advantage.

Next I will describe pneumonitis, or inflammation of the lungs, the characteristics of which are rigour or shivering fits, loss of appetite, increase and difficulty in breathing, and a similarity to the symptoms described in bronchitis, though of a more severe nature. The treatment I adopt in these cases is to place 2 drachms of nitrate of potash or saltpetre in a pint of water for the drinking fountain, or $\frac{1}{2}$ drachm of tincture of aconite to a quart of water may be substituted for this purpose. Pills containing $\frac{1}{2}$ grain belladonna extract, $\frac{1}{2}$ grain camphor, and $\frac{1}{2}$ grain carbonate of ammonia, divided into four, I administer twice a day. Binioidide of mercury ointment in a mild form may also be applied over the surface of the ribs, as recommended in bronchitis, and repeated for three or four days. In the course of a few days a cod-liver oil capsule may be given at night, or, what is preferable, one of Mr. Betty's tonic capsules. This disease is occasionally associated with scrofula, and causes the obliteration of the lung structure through its becoming firm and of a cheesy nature, differing from a purely inflammatory deposit in its uniform white colour and in its freedom from any blood-colouring matter as well as in the defined condition of its limits of extension. It is produced by hereditary predisposition, unhealthy habitations, and other causes. There are other diseases known amongst us only too well, one of which (inflammation) attacks the eye or eyes with severity, and often runs its course to the detriment and danger of the sufferer, and not unfrequently terminates in destruction or an unfavourable fungoid growth. The method I have found successful has been to give the following in a pill, according to the size of the bird:—Aloes two to four grains, ginger one grain, hydrargyrum cum creta or grey powder half a grain to a grain, and sufficient treacle to give consistency. A piece of wadding soaked in cold water should be placed on the eye and kept in its position by a piece of linen sewn over it. This prevents the bird bruising the part either with its claw or by rubbing it on the body, which must be avoided. After a few days, when the swelling has subsided, a lotion of black wash may be applied by means of a very soft feather carefully passed

over the organ once a-day. I have applied a weak solution of nitrate of silver in the same way, but this requires greater care. This disease, no matter what is done to prevent it, will at times extend and envelope the eye and its surrounding tissues as well as the bones of the orbit.

The ear is subject to an affection of a tedious nature termed canker, which is, I consider, of a scrofulous form, and requires great care and perseverance in its treatment. I would first recommend the administration of a purgative. The one I prefer is a compound aloes pill as before described. This purgative may be repeated occasionally if deemed necessary. Clean out the mucus with warm water and inject a solution of sugar of lead composed of three grains to an ounce of water, which should be warm to prevent as far as possible any shock or extra irritation. This may be continued for a few days, and then substituted by a solution of sulphate of zinc of equal strength, and applied in the same way. A very weak solution of carbolic acid may at times be used. I have frequently introduced into the ear at night a piece of wadding soaked in cold water, covering it with a dry piece and removing it in the morning, finding this give relief by softening the discharge.

Another disease that the Pigeon is very subject to is rheumatism and gout in the joints, more particularly in the wings, legs, and feet. This most frequently occurs at moulting time, through cold and inclement weather. The practice I have followed in these cases has been to give a compound aloes pill two or three times a week, at night; and in the morning following a cayenne pill. Bi-carbonate of potash or carbonate of magnesia introduced into the drinking water in the proportion of one drachm to a pint of water is attended with good effect in correcting the acidity in the blood and in its tendency to remove the deposits. The application of biniodide of mercury ointment to the joints affected, or the passing of a seton through the skin over the parts by means of a needle and piece of worsted, are methods I can recommend. In all cases the birds should be removed to some place distant from the loft, and be kept free from draughts and damp.

Before concluding my list of diseases I must not omit to mention one that at times affects our feathered friends—viz., meagrim. This is an affection of the brain arising from a derangement of the digestive organs produced by irregular and over-feeding, also by want of water. The symptoms are giddiness and stupor, in which they move round in a staggering manner with their heads inverted, the latter being caused probably by an effusion in the ventricle of the brain on the opposite side to which the head is inclined. These cases usually terminate fatally, but may sometimes be successfully treated as follows.—In the early stages by the administration of castor oil or compound aloes pills until the bowels are relieved. When the crops have been distended I have had recourse to opening them with a knife and removing the contents, with good results. This should be done on the upper part, between the shoulder and neck, care being taken to sew up the opening with a needle and silk. Pills composed of half a grain carbonate of ammonia, quarter of a grain camphor, and one grain of carbonate of soda, divided into eight, may subsequently be given two or three times a day as the case may require. A seton inserted under the skin only, across the back of the head, in the hollow space between the bones of the neck will prove useful, as will also some form of blister. Refrigerating applications (ice, ether, &c.) to the head in the early stages have a tendency to relieve.

With regard to hygiene, I would offer a few suggestions.—In the first place, a dry loft, well ventilated in the roof to allow of the escape of noxious vapours, and protected on the north-east side, should be secured. Great care should be taken at the moulting season to protect the birds from cold or inclement weather, as these are, in my opinion the causes of the greater number of the ailments to which the birds are subject. With regard to birds that are confined in lofts, I would strongly recommend a plentiful supply of grit, as without this the digestive organs become impaired and disease is the consequence. At breeding times carbonates and phosphates, such as are contained in oyster shells and old mortar, are indispensable for the proper formation of the shell. With regard to diet, I recommend, as the result of my experience, a good supply of vegetable (cooked or otherwise), and soft food such as bread, &c., once a day. This I consider necessary, as the exclusive use of hard food produces disease of the digestive organs and generally impaired health. I also recommend an occasional change of diet; peas or Indian corn soaked in water for three days and given moderately being useful in this respect. As a general food I have found tares the best. In the moulting season benefit will be derived from the introduction of carbonate of magnesia into the drinking water in the proportion of 1 drachm to a pint of water. A change of habitation of the birds, especially in the very sensitive ones, such as Carriers, frequently gives them an indisposition to feed, and unless steps are taken to remedy this, disease and atrophy will be the consequence. In such cases I have made a practice of feeding them myself at night, and for this purpose have used the soaked grain.

I have now, gentlemen, come to the end of my remarks, and have to thank you very much for your kind attention.

THE ALEXANDRA PALACE CAGE BIRD SHOW.

THE birds were shown in the conservatory, the best department of the Palace, with some good permanent aviaries in it and some passable plants. The cages were well arranged all on one level, and their occupants looked comfortable, for the temperature was pleasant and even, and there seemed no draughts. First came fifteen classes for Norwich Canaries, every one of them well filled, and in many of them nearly every bird was worthy of a notice. Norwich Canaries are always the favourites of the general public, their soft round form is so attractive. We thought the class for Evenly-marked Yellows about the best. It is amusing to listen to the exclamations of wonderment from visitors at the colour of the cayenne-pepper-fed birds, so utterly is it beyond anything conceived fifteen years ago in brilliance; in fact, this system of feeding has worked a perfect revolution in Canary-showing, for we now find special classes for birds not cayenne-fed. The class for amateurs' birds which have never won a prize was a very creditable one, and that for Yellow Norwich with dark crests very attractive. Belgians, the London Fancy, Lizards, and Yorkshire, were all well represented.

The ten classes for Mules were most interesting. First came the Yellow Goldfinch Mules, almost like Canaries with the red Goldfinch head, then the soft and pretty Buff Goldfinch Mules. The Dark Yellow Goldfinch Mules, little known save to fanciers, are very handsome, rich in colour like burnished copper. The Linnet Mules are less attractive. Last in the list of Mules came a class for mule birds neither of whose parents are Canaries. The first-prize bird in this class was a cross between a Goldfinch and Grey Linnet. We much preferred the second-prize bird—a lovely specimen of a Goldfinch and Bullfinch Mule—combining some of the beauties of both parents, most sprightly and elegant in motion. The peculiar Lancashire Coppies were rather good than numerous. British birds had many classes; that for Bullfinches was particularly good. Curious White and Pied Blackbirds, White Starlings, a Hawfinch, and a Black Bullfinch were the chief attractions of the variety class of British birds.

The foreign classes were by no means so well filled as the British. The first-prize Red-headed Cardinal was a singularly fine one. Only three pairs of Waxbills appeared, the winners being respectively Orange-checked and Orange-breasted. The Java Sparrows were all white. A pretty pair of Madagascar Love Birds were "too late." The Australian Parakeets were very beautiful, first being a Pennant's Parakeet of glorious blue and crimson hues; second a crimson-headed one, we fancy a Rose-bill. The class for "Any other variety" of foreign birds was perhaps the most attractive. The most remarkable entries in it struck us as being the second-prize Indian Bee-eater, the same exhibitor's Scarlet Madagascar Finch, and an exquisite pair of "Buetic Parakeets," shown by Mr. Groom. They well deserve their name, and are of the most delicate pink, blue, or grey hues. There were nearly one hundred entries in the Selling class, and nearly all seemed sold, as were a large number of Canaries in the general classes. Everyone can keep a bird, and such a show near the great metropolis gives a capital chance to buyers to suit their taste.

The attractions of the Show were added to by some "faked" Greenfinches lent by the proprietor of *Land and Water*. They certainly were embellished in a most artistic manner with strange parti-coloured pendant head-dresses, still it would be indeed a green fancier alone who could be taken in by such Greenfinches. We have, however, seen birds in the bird shops on the quay at Marseilles not unlike them. Hard by was a pretty automaton singing bird. We were not fortunate enough to hear it sing, but remember having seen and heard a similar one at the Exhibition of 1862.

VARIETIES.

COLONEL KING's farm on the Rio Grande, says an American paper, consists of 160,000 acres, all fenced. He has been growing in wealth since the war with Mexico, and now owns besides the land 20,000 horses, 80,000 cows, 75,000 sheep, and 80,000 mules. He employs 300 Mexicans as herders. Most of his land has been fenced in at an enormous cost. He despises "book learning," but has become well educated in the ways of the world. He lives extravagantly, and is literally "monarch of all he surveys."

It is not the quality of food, says a writer in the *Chamber of Agriculture Journal*, put into the stomach which fattens cattle, but that which is thoroughly digested and assimilated. When animals are in a state of rest, and consuming food so mixed, with water constantly before them, they take very little of the water unless the more nutritious food superadded be of a heating nature—as pea or bean meal—in too large a proportion; the safest practice is to combine crushed linseed with all these articles. Such consideration leads us to doubt the expediency of making the chief food of fattening animals stuff of which eight or nine-tenths consist of water, and more especially if unmixed with more solid food. The setting before a bullock half a hundredweight of cold roots the first thing in the morning, some hours afterwards their

allowance of more solid and nutritious food, and repeating the feed of roots in the evening, must be an irrational proceeding; while, on the other hand, a due admixture of the solid and fluid foods will probably aid the proper digestion of each.

— A CAREFUL experimenter, states *The American Cultivator*: reports that he fed two pigs, which at six weeks old were within a few ounces of the same weight, as follows:—One on skim milk with bran and oatmeal, and the other on an equal abundance of rich kitchen wash of unlimited quantity. The pigs were killed on the same day when just four months old; that fed on the wash weighing 48 lbs., the one on skim milk a little over 40 lbs. The meat of the former appeared very fine to the eye, but when roasted was coarse and greasy to the palate; while the other, though very fat, was extremely delicate both in flesh and flavour.

— LET it not be forgotten, says *The Agricultural Gazette*, that a small quantity of cake from the commencement of grazing not only economises roots but is conducive to the health of the animals, and gives additional nitrogen to the manure, without which we cannot expect to obtain an increased yield of corn. At the present moment cakes are relatively cheaper than other feeding stuffs. In fattening cattle we recommend mixing linseed cake with common cotton or decorticated. We should go in for raising all the meat we possibly can. But few come to grief who well stock their farms with good cattle, and let us not be frightened by that American bugbear, but rest assured that when the trade and commerce of England revive the world's importations will not prevent our home-fed meat from reaching a higher figure than it has yet seen.

— THE time to feed milch cows well is, says a good authority, during the whole winter, and if possible the animals should be made to gain in flesh if not already in good condition. Thus kept cows will nourish properly the coming calf, will have strength to undergo the strain on the system during calving, and will generally recover quickly; milk will be secreted naturally, and will increase until the flow reaches the full capacity of the animal, and continue so during its natural flow. With proper shelter the animal waste is reduced to the lowest point and profits show the largest. If we so feed as simply to supply the daily animal waste there is nothing left for milk. The entire food has been consumed in supplying heat, and the owner has not only worked for nothing, but loses the feed given.

— "H. C." WRITES as follows, in reply to a correspondent on chloroforming bees:—Tilt the hive slightly and run one teaspoonful of chloroform into the entrance, and immediately stop up the hole with tow or rag. As soon as the humming ceases operation can commence.

WINTERING BEES.

WITH reference to the above subject Mr. Pettigrew calls in question the correctness of my statement, "If cold is so prejudicial to bees how comes it that power is given them to resist the intense frosts of the fearful winters of Russia and North America with impunity?" and adds, "Is not this a mere assumption? Do bees bear these winters with impunity? If they do, where shall we find the evidence?" Every bee-tree in the backwoods of Canada is a standing proof that they survive without the slightest artificial aid; if they did not, as a matter of course they would entirely disappear. I am well aware of the pains American bee-keepers are at to ventilate and winter their bees successfully, besides those out of doors, in houses and cellars, but not by keeping them warm as recommended by Mr. Pettigrew, wrapping them up with carpets and sheepskins. On the contrary his own authority, Mr. Quinby if I mistake not, affords the freest ventilation by taking out the house windows, removing the floor boards, and leaving the hives inverted quite open. I cannot say I join with Mr. Pettigrew in his admiration of Mr. Quinby's "great merit" as an apiarian writer, but at the same time I must confess it has struck me as singular that Mr. Pettigrew should cling to some of his crudest of theories, even after Mr. Quinby had abandoned them himself as untenable. Your correspondent as I expected remembered perfectly the terrible frost of the morning of 24th December 1860, and narrates, "That frost killed more than three-fourths of the bees and hives in the north of England. That frost doomed thousands of hives to extinction. The country was nearly swept clean out of living bees by the cold of that night." Now it so happened that although the thermometer sank with us to several degrees below zero on that memorable morning, the ten colonies composing my garden apiary never came through any winter in finer order, and why? Because that externally as well as internally were thoroughly dry, confirmatory of the opinion I started with, that it is not cold but damp that kills. The fearful mortality described by your correspondent is easily accounted for at such a temperature when one pictures to the mind's eye the too common neglected style of the cottage apiary, with its dank damp-soaked straw skeps through the dilapidated straw hackles or old bag or carpet saturated coverings, entirely preventing the escape of the condensed internal vapours, as with the descending thermometer our poor little favourites die hard in their efforts to keep up the temperature.

That distinguished American apiarian Rev. L. L. Langstroth, a strenuous advocate for winter ventilation, writing on the 30th January, 1857, says:—"This month has been the coldest on record for more than fifty years. My hives have been exposed to a temperature of 80° below zero. . . . No. 1 was again examined, and the bees found in good condition. The central comb was almost filled with sealed brood nearly mature, all the combs were free from mould, and the interior of the hive was dry," and on the same page the same apiarian adds, "Mr. E. T. Sturtevant, of East Cleveland, Ohio, so widely known as an experienced apiarian, in a letter to me thus gives his experience in wintering bees in the open air: 'No extremity of cold that we ever have in this climate will injure bees if their breath is allowed to pass off, so that they are dry. I never lost a good stock that was dry and had plenty of honey.' He goes on to narrate how that in the winter of 1855-6 he had twenty stocks standing in a row. 'One was a hive suspended 20 inches from the ground and without any bottom board. The chamber for surplus honey boxes was open to the north, and had eight one-inch holes all uncovered.'" Not to encumber space, suffice it to say that the nineteen hives all perished through the severity of the winter, while the one remaining open and exposed came out strong and healthy.

To take a case nearer home, a bee-keeping friend in a neighbouring county wrote me so lately as the 9th inst. deploring the loss of a favourite hive as follows:—"I must blame myself for the death by following out Mr. Pettigrew's plan of coddling. Three weeks ago about one-third of the bees were dead, and fearing the rest would succumb I shifted its mouth from the opening in the window sill and heaped on woollen cloths. Yesterday being a fine day all were dead but about fifty, which were all damp."

Mr. Pettigrew, while commenting on my observations on runaway swarms preferring to take up their quarters in the coldest or north aspect of our own and neighbour's roof while all other aspects were alike open to their choice, does not doubt the "truth" of my remarks, but thinks it "a mere fancy" on my part of the bees so coming to enjoy "the most thorough and undisturbed dormancy with the consequent minimum consumption of store;" but the fact remains that they did so come, and in no case to people empty comb, and even if they had would only go to prove they inherited the like predilection for such exposure as preceding generations. I might have added that at the same exposure they also enjoyed the maximum shade during the working season. Summer suns never roasted out my garret tenants to swarm, nor winter's blinks heated the slates to bring them forth to drop at a lower temperature than 50°, the evils of which I notice Mr. Pettigrew, in common with all adherents to the "warm" theory, suffer to their cost.—A RENFREWSHIRE BEE-KEEPER.

THE INTRODUCTION OF THE LIGURIAN OR ITALIAN BEE INTO ENGLAND AND GERMANY.

THE following account of the introduction of the Italian bee into Germany from the pen of Dr. Dzierzon, on the occasion of the twenty-fifth anniversary, which occurred on the 12th inst., having been translated from the *Bienenzeitung* by my friend Mr. Henry Dieck, I thought it of sufficient interest to claim a place in your columns, more especially as the notice of bee-keepers in this country was first drawn to this variety of bee through the medium of your Journal nearly nineteen years since.

Many of the readers of "our Journal" may recollect a notice which appeared on the 19th July, 1859, announcing that a new kind of bee had been offered to British bee-keepers, signed "H. T.," and inserted by my friend the late Mr. Henry Taylor, author of "The Bee-keeper's Manual," and contributed to the pages of this Journal. This was an extract from a letter addressed by M. Hermann of Switzerland to my firm, and attracted the attention of your able correspondent the late Mr. Woodbury, who immediately sent to the address given for a queen. Thus a new era in bee-keeping was commenced in England. Bearing in mind this interesting circumstance, it occurred to me that the opinion of the great apiarian of the good qualities of the Italian bee after an experience of a quarter of a century might very appropriately appear in the *Journal of Horticulture*.—ALFRED NEIGHBOUR, 140, Regent Street, London.

THE TWENTY-FIFTH ANNIVERSARY OF THE INTRODUCTION OF THE ITALIAN BEES.

"I had been practising bee-keeping for about twenty years, and had written my first work on bees, entitled 'Theory and Practice,' without being aware of the existence, in addition to our common grey or black bee, of other races and varieties of the honey bee of quite a different colour. I certainly knew from the *Bienenzeitung* of the peculiarity of the heather bee to make preparations for swarming by breeding drones in hives in which there is a young queen hatched in the same year, while the common bees never do; and I had also read in Virgil while yet a student that there were two kinds of bee kings, those shining like gold, and others of a dark colour and an inactive disposition, the latter being compared by the poet to a fatigued traveller who goes along

labouring through the dust. This description, however, I looked upon rather as a poetic licence, and thought it applicable to young queens of generally a bright colour with frequently rather yellow rings, and to old queens mostly of quite a dark colour. When, however, I had become acquainted with the Italian bee by actual observation, it was quite clear to me that the poet when describing the two kinds of bees had in his mind the two varieties of bees—viz., the golden yellow one and the common grey or black bee, which are both met with in Italy at the present day, and to the former of which he decidedly gave the preference.

"The introduction of the Italian bee into Germany has been quite an event in the history of native bee-keeping. If I am not mistaken, I was told by Von Hruschka that a monumental stone had been placed in the apiary of Mr. Prolius of Mira, on the spot which had been occupied by the hive that was sent to Silesia. But if this event appears worthy to be celebrated by the senders of the bees, how much more important ought it to appear to the receivers. At the beginning of the present year just a quarter of a century had passed since this memorable event, which certainly deserves to be kept in mind and to be specially mentioned in a prominent place of the organ of German bee-keepers. I will first give the history of the introduction of the Italian bee, and then mention the consequences of its introduction—the influence it has had on theory and practice.

"The first information of the existence of a differently coloured bee in several parts of Upper Italy I obtained from an article in the *Bienenzeitung* by our great bee friend, Capt. Conrad Von Balenstein of Chur in Switzerland. He related how during the campaigns in Italy he had become acquainted with a bee with bright yellow rings on the abdomen, how it proved to be an excellent means of deciding many a question respecting the propagation of bees which at that time was doubtful, and how on his return home he had a stock of yellow bees brought to his apiary from beyond the Alps. From that time the Italian bees occupied my thoughts, and I meditated on the ways and means of obtaining possession of such a colony. In the beginning of the year 1853 my ardent wish was fulfilled in a manner which will be described in a future issue."

NEW EDITION.

The Apiary: or Bees, Bee Hives, and Bee Culture. By ALFRED NEIGHBOUR. London: 1878.

HAVING spoken approvingly of former editions of this work we need only make the following extract from the preface—"The present issue of our handbook may be fairly said to be really a new work. Not that the greater portion of it has been consecutively rewritten, nor yet that the larger half of the former matter has wholly disappeared; but the additions of entirely new sections and half-sections, the transpositions with a view to facilitating reference, the erasures of what is either out of date or only repetition—in short, the thorough overhauling of the text from beginning to end—are such as to render the form in which it is now presented a new book rather than an ordinary fresh edition."

OUR LETTER BOX.

SPANISH, MINORCA, AND ANDALUSIAN FOWLS (H. S. S.).—They are described in our "Poultry Book for the Many." The book you name can be had in sixpenny numbers.

BIRD HOARSE (Bird Fancier).—It is usually caused by the bird's cage hanging in a draught, sudden changes of temperature, or a damp aviary. We have found great advantage by putting some tar in the water from which they drink, which has quite cured some cases if taken early, and before the lungs become seriously affected. Bread and milk, and plenty of chickweed and groundsel, are also beneficial. One gentleman strongly recommends the use of rice water as a cure for asthma in Canaries.

FOWLS LOSING FEATHERS (Constant Subscriber).—We expect the feathers do not drop, but are pulled out by the other birds. It is a very common thing with fowls in confinement, but we have never known it happen with birds at liberty. It is a sign the secretions are at fault. Either the food they get is wrong, or they are debarred from something they require. We think your feeding likely to cause it. Indian corn is a capital help, but fowls fed on it entirely become excessively fat, and that induces disease of all sorts, among others a distaste for food. If at large they would find the natural remedy. In confinement they take that which most resembles it—viz., feathers. They will strip each other; but as the practice generally originates with one or two birds you must watch, and when you see one picking another remove her. Your feeding is bad; have your barley ground, it will pay for grinding. Give barleymeal or ground oats morning and evening, maize or table scraps at the mid-day meal. If they have no access to grass let them have large sods cut with plenty of fresh earth and thrown into their runs. Give neither rice nor middlings. It is impossible to say how much sixty fowls should consume unless everything is known about their runs and their opportunities of getting food. We have had Langshans, but could not discover they were in any way superior to ordinary breeds. In appearance they are, we think, inferior to most.

WEAK HIVES (Apis).—The sooner you unite the bees of your two hives the better, for they are beginning to breed. The way we unite bees at the present time is very simple and successful. Both lots of bees are sprinkled with good warm syrup well minted at sunset. The doors of the hives are closed and all taken into a room or hothouse and left there for an hour or two. The syrup makes them both merry and noisy. The hive of which the bees are to be surrendered is lifted off the board perpendicularly 2 or 3 feet and brought on it with a great thump, causing almost every bee to fall on the board. The other hive is lifted off its own board and placed over them.

This is but the work of a minute of time, done in candlelight, and as soon as it is done we pick up the candle and leave the bees to themselves to arrange the terms of union and goodwill. Hundreds of hives have been united by us thus in winter and spring without a single case of failure. If all the bees are not shaken out by the first thump they are cast out in front of the united bees by another attempt, and they soon are attracted to the hive by the noise. Next morning before daylight they are placed on their stand in the garden. Your idea of placing the one weak hive on the other is not a good or safe one. In the work of uniting swarms it is desirable to kill the oldest queen, and this is easily done in autumn when we have daylight; but in candlelight it is very difficult to see a queen in a swarm, however small, and is rather dangerous to search for the queen in candlelight, as the bees fly and crawl towards the light.—A. P.

DESERTED HIVE (Henry Coy).—If the combs of your deserted hive are young—built last year, you may put a swarm in it at the swarming season. If the combs are dark-coloured and old a swarm will do better in an empty hive than amongst them. By using empty hives we are certain that swarms begin their career with good constitutions and free from disease of any kind. If the weather become unfavourable for comb-building the administration of 2 or 3 lbs. of sugar will enable them to build some pure virgin combs. Old combs should never be used for supering.

BEE STINGS (F. J.).—"B. & W." says that his bees are always at war with him. He adds, "I have never been able to conquer their antipathy, so I take good care to quiet their nerves with a dose of smoke, and to protect myself before I do anything among them. I fear you must do the same; yet my old friend Mr. Woodbury could do anything with his own bees, whereas in attempting to deal with mine he was stung, which looks as if it were possible to accustom them to the presence of their owner and his manipulation; but I suffer so much from irritation after being stung that I have come firmly to believe, at least in my case, that discretion is the better part of valour."

METEOROLOGICAL OBSERVATIONS.

REMARKS.

- 13th.—Dull damp morning; brighter with a little sunshine in afternoon; fine but damp in evening.
 14th.—Very wet morning; fine in afternoon and evening; very dark for about five minutes at 4 P.M.
 15th.—Damp morning but fair; rain commenced 1.30 P.M.; fine moonlight evening.
 16th.—Dull and damp in early morning; after 10 A.M. fine and sunny; rather cloudy in afternoon; drizzling rain in evening.
 17th.—Beautiful day, bright sunshine, and quite spring-like; moonlight night.
 18th.—Another bright, fine, and pleasant day throughout.
 19th.—Very foggy until 2.30 P.M., clearer afternoon; fine evening.
 Much warmer, especially on Sunday and Monday. Air damp throughout the week.—G. J. SYMONS.

COVENT GARDEN MARKET.—FEBRUARY 20.

A VERY quiet market this week, with all classes of fruit now coming short. Outdoor vegetables are plentiful and prices low, but forced goods are in demand. Large quantities of Broccoli are arriving from Cornwall and the Channel Islands.

From observations taken near London during forty-three years, the average day temperature of the week is 49.5°; and its night temperature 32.7°.

MUSHROOM CULTURE.

AMONG the many productions of the garden to which a gardener has to direct his attention the Mushroom ranks with the most delicate and highly-prized, especially by those who have a liking for this most delicious vegetable; and yet, notwithstanding this, how seldom one sees an article devoted to its culture compared with the numerous opinions and experiences of different gardeners relating to vegetables that do not rank so high.

The culture of the Mushroom is one of the most interesting duties with which I, as a gardener, am acquainted, and if your space will admit of a few details I shall have much pleasure in giving them.

I will commence with spawn. "The most essential requirement to grow Mushrooms successfully is good spawn," says "A KITCHEN GARDENER," and who will dare to deny the truth of this statement? But I must confess that after all good spawn as regards Mushrooms is only on a level with good seeds in the culture of other vegetables, and unless the good spawn and the good seeds have the proper treatment the one will not give satisfaction more than the other. Spawn to be good should not be in a too advanced stage; in fact, as long as the fibres are just discernible and have worked all over the cake, that is all that is required, as if the fibres are too large the spawn will not keep good so long, nor will the products be so certain. It is also necessary that it should be kept perfectly free from damp.

Whilst dwelling upon this head a few remarks upon the making of spawn bricks will not be out of place. The compost should consist of one-half of good stiff loam void of fibre, one-fourth of fresh cow dung, and one-fourth of horse droppings from the stable, with which there should be enough of short straw to hold the whole together when made into bricks. This compost should be well mixed and knocked up like mortar, and allowed to lay in a heap a day or two; the compost is then ready for making into bricks. I omitted saying that a little water may be used in the mixing, but no more than is absolutely necessary. A mould similar to those used by brickmakers should next be provided, but not made quite so deep nor so heavy as those used for clay. Having a heap of the compost on the potting bench, a pail of water, and a little sand handy, the operator may commence (spawn) brickmaking in earnest. Fill the mould with the compost, ramming it well into the corners so as to turn out a perfect brick; work the mould to and fro a time or two, keeping it firmly pressed to the bench, and with a piece of board made to fit loosely in the mould smooth the top; make two holes in the brick with the finger, slightly sand it, place the board on, move the whole sharply to the left, raising it at the same time, and with the two thumbs on the board press out the brick on to a handbarrow, which should be slightly sanded, and so proceed until a sufficient quantity be made. The pail of water is necessary for wetting the bench, and the piece of board to facilitate the smoothing part of the business. An

active man may soon produce enough bricks for any ordinary demand.

The bricks should then be placed in a dry airy situation, but not in the full glare of the sun, as they require to be dried gradually. Just before they are quite dry fill the holes with spawn from a brick which is known to be good, pressing it very firmly, and sealing it in with a mixture of clay and cow dung. This done, place the bricks on edge until the fresh paste is dry, when the whole should be collected and closely stacked in the Mushroom house to heat; if there is not enough bulk to cause heat of themselves the temperature of the house should be raised to meet the case. If a temperature ranging from 70° to 75° is maintained in the stack, in a month or six weeks the majority of the bricks will be found white with spawn and have a strong smell of Mushrooms; these should be put away in a dry place until required. By adopting this method the cultivator knows the sort of spawn he has to depend upon, and it is a method that I can from experience strongly recommend.

Preparing the material for making the beds is the next point to be noticed, and in this I differ slightly from the generality of cultivators, who do not hold with letting the dung ferment to any great extent. The method I adopt is as follows:—Every morning I have all the droppings from the stable collected and thrown into a heap, which is turned every morning, when fresh droppings are added, mixing the old with the fresh, beating it slightly with a fork. This is continued until sufficient droppings are collected; it will then require turning once or twice more in order to sweeten the last-added droppings.

Making the bed. Here also I differ from some who advocate deep beds. In my house I have three beds 4½ feet by 6½, and in measuring the depth previous to writing this to be the more accurate in my statements I find they are only 8½ inches deep, including soil, and the quantity of Mushrooms gathered from these beds for three months past is ample proof that a greater depth is not necessary.

The material should be made as firm as possible in the beds, and the temperature narrowly watched, and so soon as it has declined to 80° no time should be lost in inserting the spawn, which should be about the size of a hen's egg, and inserted 2 inches deep and 9 inches apart over the bed. This done tread the bed firmly, leaving it perfectly level. In the course of a few days the soil, which should be rather stiff than otherwise, may be placed on 2 inches deep and be made firm and level. The bed should then be covered about 2 inches deep with hot droppings that are suitable for making a bed; the whole is then complete. On the same day of the month following on which the bed was spawned the covering should be removed. I repeat the same day of the month, for I venture to say if these rules are strictly carried out by that time the spawn will be showing through, and if the covering be left longer much of the crop will be damaged.

I have a bed at the present time which was spawned on the 9th of January and to-day (February 16th) it is completely covered with Mushrooms, some of which are as big as a large shirt button.

The temperature of the house should range from 55° to 60°, and as little fire heat as possible should be employed.—
G. W. PRIOR.

PRUNING ROSES.

I THINK someone last year about this season wrote to the Journal expressing surprise that no one had written any hints on pruning Roses. Lest he should again bring this charge I beg to offer a little advice on this point. At all events, what I have to say is the result of much experience and also very severe loss.

All kinds of fads have I tried in pruning, and most of my experiments have been accompanied by the loss of a very large number of trees; also, I must tell your readers that I never write advice on any critical matter of Rose culture without strengthening my own opinion by asking the advice of great trade growers.

I remember when I was a curate in Sussex being called upon to read a paper at a clerical meeting upon a most difficult subject. This I managed to do with great success by calling in the aid of my kind old vicar, who let me pick his brains by the hour together. When complimented on the paper I freely acknowledged that in fact I was giving them the ideas of the good vicar as well as my own, and that they owed to him and not to me any benefit that they might have derived from the effort. "Never mind that," was the reply; "we would much rather hear the vicar through you." So in a similar way I may say to anyone who may feel inclined to kick at a conceited parson who lives in the "wylds" of Dorset from offering his advice upon any point which is interesting at the time, that it is not only my duty as a member of your staff to express my ideas, but that I take great care that those ideas shall be sanctioned by the experience of others whose sole business in life is to cultivate thousands of Rose trees.

First, then, as to the time of pruning. Writing these notes on February 19th, I say without the slightest hesitation that now is the time to commence pruning for all those who live in the south. What do I mean by the south? Well, I would define the south by the old historical division—south of the Trent.

I do not advise people who live in Yorkshire or Lancashire and the adjacent counties, and of course further north, to prune for another month, but all others should begin now. I am not only speaking to exhibitors, but to all Rose-growers.

I am aware that many cultivators of the garden Rose (if I may use that expression to distinguish them from exhibitors) prune in November, or in the autumn; but even then, I suppose, will find it necessary to re-prune in the spring. I state the present as the time to commence pruning for this reason—the Manetti cannot bear late pruning. I am writing principally of this stock. Mr. George Paul has over and over again impressed upon me and my friends that it is almost fatal to defer pruning till late in the spring. Mr. Walters of Exeter gives the 12th of February as the best date for commencing work in these parts, and no one is more successful than he in growing good plants. Commence pruning, then, now at once with the Manettis. Leave the Briars till all the former are done, and leave your Teas for another month or six weeks.

Next as to the mode of pruning. Shall I cut hard or easy? Shall I cut my plants almost down to the ground, or merely snip them as a Billy goat would if turned loose in the rosery? Before I answer such a question as this I must know what sort of plants I have to deal with. If they are a lot of young beauties bought last autumn from the great nurserymen—what we call one-year-old cut-backs—then be very tender with them; spare the knife, take much time, handle them with the greatest care. Take hold of the plant with one hand and cut each shoot down to a sound outside eye. Any direction as to number of eyes it is impossible to give, for the principal aim is to find a good, bold, sound, outside eye. By outside I mean one that looks towards the sun or light. If, however, I have to deal with old well-established plants, jolly old customers that look at you as much as to say, "Come along with your knife and do your worst. I don't fear you; I will soon turn your steel and make you weary of pruning me!" As for eyes they have none; their hides are too hard, their bark as well as their "bite" is very severe, and their thorns are like those of the Prickly Pear, so cut away at them, and the eyes will in due course appear, followed by most luxuriant growth.

But among Hybrid Perpetual Roses there are certain sorts which require different treatment to the majority. For instance, spineless or softwooded Roses like Comtesse d'Oxford, Victor Verdier, Mdle. Eugénie Verdier, Marie Finger, and such like will not stand such hard pruning as the others. Then weak growers must be differently treated. You must not attempt to deal with Marquise de Mortemart as you would Abel Grand. You must be very tender to the former—just pruning it, no more. The robust growers like Madame Rothschild do not require the hard treatment as such vigorous fellows as Edward Morren or Charles Lefebvre.

The Teas when their time comes must, of course, meet with very tender treatment. You have here to deal with most delicate ladies, and you must trim their hair with great care and give them every attention, and not think for one moment that you can handle such aristocrats as you did their bucolic brothers. Spare the knife here; just tip the shoots and thin-out the weak and decayed wood.

Let your reason guide you in all you undertake, and you will, I think, succeed in doing justice to your plants.—
WYLD SAVAGE.

DUKE OF BUCCLEUCH GRAPE.

VERY rarely indeed do I write a line on any subject that I am not intimately and practically acquainted with, therefore I had better be honest and state that I have never grown a rod of the Duke, so that my remarks may go for what they are worth. "Not worth much," perhaps some may be ready to say, yet possibly they may be worth as much as those of some disappointed growers; at any rate, they are not born of prejudice.

I esteem the Duke of Buccleuch the grandest white Grape in cultivation, yet I do not grow it, and for the sake of consistency I may state that it is because I have not a chance of doing so. I am not one of those so circumstanced as to have the privilege of ordering and growing every new Vine that "comes out," yet I am glad to have some compensatory advantages. Noblemen and gentlemen have their fancies, and the nobleman for whom I have had the pleasure of growing Grapes for several years will not permit any other sorts than Black Hamburgh, Muscat of Alexandria, and Lady Downe's in his vineries. With those he is satisfied, and boasts that he has a better supply of Grapes than have others who grow several varieties.

But to "the Duke." Although I have not grown this, the best-abused Grape in cultivation, I have seen it grown—seen it succeed and seen it fail, and I am sorry to say that the failures have preponderated. Several gardeners will probably be surprised to hear that Mr. Douglas cannot grow the Duke. I am not surprised, for according to his teaching he grows Vines under a high temperature, which will produce good Black Hamburghs, but I am very doubtful if the treatment is so suitable for "the Duke." It would be instructive to know under what conditions as to temperature the Duke of Buccleuch is grown by Mr. W. Thomson at Clovenfords, Mr. D. Thomson at Drumlanrig, and by "COLUMBUS." I shall be much surprised if their success has been attained by the aid of such high night temperatures as I presume by his writings that Mr. Douglas adopts in his Black Hamburgh houses. The Duke is a Vine of exceedingly succulent habit, and a high night temperature and much atmospheric moisture are, I think, foreign to its requirements. I doubt if this Vine, like other new and highly cherished plants, has not been injured by kindness.

From its nature, too, it is reasonable to suppose that it cannot endure crowding so well as many other Grapes. It must have abundance of space, which, in conjunction with a comparatively low night temperature and very little of atmospheric moisture, conduces to short-jointed growth and fruitful wood, the reverse of these conditions producing wood of a contrary character. "The Duke" has generally been either planted in old Vine borders (which seldom results satisfactorily), or has been worked on old Vines and has not received that amount of space and light that would have been secured in new vineries.

I had written thus far on the arrival of the Journal containing the reply of "COLUMBUS" to Mr. Douglas, and I perceive the discoverer (not of a new continent, but of a mode of growing successfully a new Grape) has anticipated my inquiry respecting the temperature, which I am not surprised to see is a low one. Mr. William Thomson states the treatment the Duke receives is "of the most ordinary kind," which I pre-

sume includes a low night temperature. Will Mr. David Thomson, who I know grows "the Duke" successfully, oblige by communicating his experience on this matter? I ask this because the best Vine of the Duke and the finest Grapes I ever saw were growing in the vinery of an amateur which did not receive any artificial heat at all.

There is another aspect of the question that may be worthy of some consideration. Has not the Duke sustained injury by high-pressure propagation? Experience teaches that a Vine cut from imperfectly ripened wood does not make such a satisfactory cane as that from an eye which has been taken from wood thoroughly matured. Such was the demand for the Duke when its fame was first proclaimed, and subsequently ratified by the visit of Mr. Barron to Clovenfords and the award of the Fruit Committee of the Royal Horticultural Society, that every available portion of cane was propagated from, whether the wood was ripe or unripe. I do not suggest that this was done by the raiser of the Duke, but by those who purchased the Vine "for stock." I think I may go further than that, and presume that many Vines were raised by striking the young shoots when they were not much thicker than knitting needles, a mode which is not uncommon in increasing the stock of new Vines which have won high honours, but withal, as I believe, an unnatural mode, which promotes a debilitated constitution. It is an axiom that a bad cutting cannot make a good plant, and hundreds of the Duke of Buccleuch Vines have been raised from bad cuttings. Vines raised from highly forced young shoots can hardly fail to be succulent in their nature, and I for one cannot regard them as attaining with any certainty a sturdy habit, hardy constitution, and a fruitful character. There must be a cause for the Duke succeeding in some places and failing in others, and since failures have occurred with admittedly good cultivators it is reasonable to suppose that the cause is a constitutional one, and that the evil or weakness, or whatever it may be called, has been acquired since the Vines at Clovenfords were officially inspected and favourably reported upon by a competent authority. It is difficult to either prove or disprove that high-pressure propagation is a chief source of the evil that so many complain of; but if it is, the evil will in time cure itself, and the Duke, as "COLUMBUS" observes, "will find its proper level." But, apart from the constitutional aspect of the question, I think that a high night temperature is contrary to the natural requirements of the Vine generally and to the variety in question particularly. I am anxious to hear what other cultivators have to say, and shall be particularly glad if Mr. D. Thomson will tell us just what he thinks on the whole subject.—A NORTHERN GARDENER.

NATIONAL AURICULA SOCIETY, SOUTHERN DIVISION.

THE scant encouragement given to the exhibition of this beautiful spring flower by the two great metropolitan societies (owing no doubt to the force of circumstances) led, as we know, last year to the establishment of a branch of the National Auricula Society in London; and through the energy of Mr. E. S. Dodwell and the liberality of such generous patrons of horticulture as Messrs. McIntosh, Whitbourne, Wilson, and others, a most liberal schedule was prepared, and considering the season a successful exhibition was held at the Crystal Palace. The same arrangements have been made for the present year, although the Hon. Sec. has unhappily been laid by with severe illness and has not consequently been enabled to canvass so extensively for the Society as he has done before. Deaths, too, have occurred amongst the subscribers, and therefore it is very desirable that all who feel interested in the growth of this beautiful spring flower should aid the movement. The schedules are issued, and can be obtained from Mr. Dodwell, 11, Chatham Terrace, Larkhall Rise, Clapham, S.W. Should the season be propitious we may hope that the 25th April will see a still larger display of Auriculas and Polyanthus at the Crystal Palace than even that of last year.—D., Deal.

OUR BORDER FLOWERS—POPPYWORKS.

THE Horned Poppies are a very small family of plants, but are none the less interesting on account of their limited numbers. We claim at least one of them as our own. The plants are found on some of our seacoasts, and when seen in their native homes have a very striking appearance. *Glaucium luteum* is covered with a fine glaucous hue, and has dew-like

bespangled sea-green leaves, which give the plants a very ornamental appearance. The whole plant abounds in a yellow juice, which is very fetid and possesses poisonous properties. *Glaucium luteum* is an attractive seaside plant. The flowers are very short-lived, but are produced in rapid succession, affording a fine display for a long time. The flowers are succeeded by a large seed pod often a foot in length, having the form of a horn, hence the appellation of Horned Poppy. The plant requires room to develop itself in cultivation, when it often attains the height from 2 to 3 feet. When well grown in the border and shrubbery the plants are very effective. They

Fig. 25.—*Glaucium luteum*.

can also be turned to good account for edging or bedding purposes as white-leaved plants, but to have them dwarf for this purpose the flower stems must be pinched out. *Glaucium fulvum* is much the same in appearance, having somewhat deeper-coloured flowers. G. Fisheri is the most attractive from its having much deeper-coloured flowers, nearly approaching an orange colour.

The plants are easily increased by seed sown as soon as ripe. The seedlings appear in the autumn, and flower early in the following season. When sown in spring the plants flower in the autumn. They are also increased by side shoots taken off with a heel, smoothed with a sharp knife, the cuttings being inserted in sandy soil in well-drained pots, and placed in a cool shaded pit or frame. The plants thrive in any ordinary garden soil, but are the better for liberal treatment. They are regarded by some as biennials, but I have had them last for years, and I cannot but regret that they are so seldom seen in cultivation.—VERITAS.

VEGETABLE CULTURE.

CHAP. IX.—THE ONION.

SOME suppose the Onion to be indigenous to Africa, but this and the date of its introduction into this country are not definitely known. It is well known, however, that it has been cultivated in Britain from a very early date. There are very few soils or situations in which it will not succeed to a certain extent, but the size and quality of the bulbs are influenced greatly by soil and situation, especially the former.

The best soil for producing a heavy crop of Onions is a moderately heavy loam. A soil half clay is neither good for the seed germinating nor for the bulbs swelling freely; at the same time the Onion must have something substantial to do well, and a light sandy soil with little in it will never produce a satisfactory crop. Respecting the two extremes, when a clayey soil is the only one available the part intended for the Onion crop should be dug up roughly early in autumn, and at the same time a large quantity of good manure—coal and wood ashes, road scrapings, and stuff of this description—should be incorporated with the soil. A week or so before

sowing time a quantity of old decayed vegetable soil, any old soil in which plants have been grown in pots, and a general mixture of open materials of this kind, should be spread over the surface and worked in with a fork. Onions equal to the best I have seen have been produced on clayey ground when treated in this way. Extremely light soil is more difficult to deal with than heavy. In the place of wood and coal ashes, road scrapings, or other light material, a quantity of heavy soil and strong manure should be dug in, and this should only be a few inches below the surface. Before sowing, a liberal quantity of thoroughly decayed manure should be forked into the surface, and the seed when sown should be covered over with old vegetable soil.

We always sow Onions after Celery and the plan answers capitally. The soil is very heavily manured for the Celery, and after it is cleared off the ground is merely turned up roughly without adding any manure. It is generally about the beginning of February before the Celery is cleared off the part we want for the Onions. After lying rough for two weeks or more according to the weather a thin coating of the old decayed vegetable soil is spread over the surface with a sprinkling of soot and a little lime, and the whole is lightly forked-in a few days previous to sowing. Moderately heavy soil generally contains more grubs and insects than very heavy or light soil, and the addition of a little lime and soot is an excellent precaution against the subsequent depredations of all such pests. Indeed it is a very safe plan to apply these two useful ingredients to all kinds of soil intended for Onions. In all cases the soil should never be dug over unless it is dry. This must be particularly attended to when the ground is being forked over immediately before sowing the seed, because when the soil is trodden on and worked when it is wet or adhesive it cakes and hardens as soon as the weather is dry for a week or two, and this is anything but beneficial to any kitchen garden crop, more especially the Onion.

Spring Onions may be sown at any time from the middle of February until the end of March. When the soil is dry enough no opportunity should be lost after the first-mentioned time. The most convenient way is to sow in beds. The number and length of these must of course be regulated according to the demand and the proportion of ground to spare, but the width of the beds should be between $3\frac{1}{2}$ and 4 feet, with 15 or 18 inches of footpath between the beds. In making the beds first measure them off and place a small stick at the margin of each; then stretch the line along to show where the alley will be, when the soil to about the depth of 2 inches should be thrown out of it on to the beds. This may be done roughly until the beds have been got into form and the seed sown, when the edges of the beds should be cut straight and the alleys be neatly raked. The seed may either be sown broadcast or in rows. For convenience in after-culture we always adopt the latter plan. After the bed has been roughly formed drills 6 or 8 inches apart and about $1\frac{1}{2}$ inch deep are drawn across the bed; the seed is then sown thinly in the drills. When the soil is very good the seed may be covered over with it to the original level of the bed, but when heavy the drills should be filled up after sowing with some light old soil from the potting shed. In light soils, when the surface is very dry after sowing the seed, the whole bed should be firmly trodden with the feet and afterwards raked smooth. Heavy soil should not be trampled on. In sowing broadcast the surface of the bed should be made moderately fine, and the seed must be covered with about half an inch of soil from the paths. After finishing the beds at sowing time they require no further attention until the plants are an inch or two above the ground. When they are sown broadcast little or nothing can be done to them when of this size, but when in rows the Dutch hoe should be carefully run between them. This is a great benefit to the plants on all kinds of soils, but more especially on heavy ground. After the first hoeing this operation should be repeated every ten days until the plants are about half grown, and after that the beds should always be kept perfectly free from weeds and open on the surface.

Thinning should begin when the plants are 3 or 4 inches high. At first only those which are nearly touching each other should be drawn out. These thinnings make excellent salad. The second thinning may take place a week after the first. This time the plants should be left about 2 inches from each other. This allows them to grow to a considerable size, but as soon as they are beginning to meet again every other plant must be pulled out. As they have a good hold of the ground by this time they should only be drawn out

immediately after rain when the ground is soft, otherwise many of them will snap off by the smallest part of the stem and grow again. This last thinning will leave them 4 inches apart, and useful-sized bulbs can be grown at this distance, but those of a large size must have more room. The most profitable way of growing them, however, is not to thin them out systematically, for it will be observed that some of them are nearly as thick in the neck or stem as they are where the bulb should be, while others are small-stemmed and much larger at the root. These "thick necks" never make good keeping bulbs, but they do very well for drawing for immediate use; and every one of them should be drawn out as they are wanted, to give more space to those forming large bulbs. Broadcast plants must be thinned-out in the same way, and they should be left as evenly over the bed as possible.

By the beginning of August the crop should be fully grown, and that month should be devoted to their ripening. When the growing season has been very wet it very often happens that by the end of August, although the bulbs are fully grown, the tops are quite green, and when this is the case it is not wise to pull them up, but the stem should be given a twist and the top be laid flat down on the ground. After lying for a fortnight the root will be quite ready for lifting, but this should only be done when they are quite dry. As soon as they are pulled up they should be laid on their sides on a gravel walk or any dry surface fully exposed to the sun. Here they should be turned over every other day, and allowed to lie for eight or ten days, when they may be removed to a dry airy shed or loft. They keep well in a place of this kind during the winter provided frost is excluded from them. They should not lie in heaps for any length of time. The best way of preserving them is either to spread them out thinly or make long ropes of them and hang them up. The best should only be done the latter way, and the worst kept loose to be used first. When properly kept, Onions will remain fit for use all through the winter and on to May.

This is the manner in which the bulk of the Onion crops are grown; but most practical gardeners grow what is called an autumn-sown crop, which serves several useful purposes. The autumn sowing should be made during the first or second week in September. The ground should be prepared and the beds made in the same way as for spring sowing; but a very small bed will suffice at this time, as the plants are not thinned-out, but allowed to remain in the bed during the winter and transplanted early in spring. If the position of the seed bed be well sheltered and the ground is not retentive it is not necessary to protect the crops in any way during the winter. As soon as the ground is in good working order after the beginning of February a piece of it should be prepared in the same manner as for sowing the spring crop. Rows are then marked 15 inches apart, and the plants are lifted and dibbled into these 5 or 6 inches apart. As the season advances the hoe must be run through the beds frequently. In April those showing thick necks may be pulled out and used, and the others will have formed good-sized bulbs for use in May and June. Onions cultivated in this way generally attain a greater size than those from the spring sowing, and for exhibition purposes well-fed autumn-sown bulbs are preferable to those sown in spring.

When the ground has been prepared as directed few or no insects will disturb the plants, otherwise there is a small white maggot which cuts the plants off at all stages of their growth and sometimes destroys the whole crop. A few Carrots are sometimes sown with the Onions for the worms to feed on instead of eating the Onions, but this is only a partial remedy. Where it is impossible to prepare the ground properly before sowing the seed, as soon as any of the plants show the slightest sign of becoming yellow mix a quantity of soot and lime together. Spread this between the plants and hoe it in. The first shower will take it to the roots and give the vermin a check.

Giant Rocca, Large Flat Tripoli, and Giant Madeira are the best varieties of Onions for sowing in autumn. For sowing in spring preference should be given to James's Keeping, Nuneham Park, Bedfordshire Champion, Danvers Yellow, and Improved Banbury. The small Silver-skin is the best to grow for pickling. It is treated like the others, excepting that the seed should always be sown broadcast and the plants be grown closely together.

The Potato Onion grows in clusters, which are divided and planted annually. It may be planted at the same time as the autumn-sown Onions are transplanted from the seed bed;

indeed, we generally follow up these on the same piece of ground with the Potato Onions. The whole crop is lifted in June or July and stored like the other crop. When any are used the clusters are divided and a few of the best left for planting again. When planted the bulbs are not wholly covered, but about the time they are fully swelled all the soil is removed from round the bulbs, so as to allow them to swell freely and ripen at the same time.

It is so unnecessary to grow the Tree Onion, and it is so very little cultivated, that making no remark on it here cannot be regarded as an important omission.

Garlic and Shallots succeed well when cultivated like Potato Onions, that those who are successful with the one will not fail with the others.—A KITCHEN GARDENER.

JUDGING ROSES.

I HAVE been much interested in the discussion on Rose judging provoked by Mr. Curtis, and quite agree with my good friend "WYLD SAVAGE," that the plan proposed by that excellent rosarian is simply impracticable; neither do I think that such a minute account of points is, as a rule, at all necessary, except in cases where the competition is unusually close. In order to ensure Roses being judged correctly, and to the satisfaction of the exhibitors generally, care must be taken in the selection of the judges, and only those should be chosen who are successful exhibitors themselves and who live amongst their Roses. It is only men like these who really know what blooms each variety is capable of producing, and to them alone should such responsibility be entrusted.

I quite agree with "D. Deal," that "good judges need not be taught;" but, as at some country shows there may be a difficulty in procuring the services of efficient men, it may be advisable for the National Rose Society to lay down some rules for their guidance, and the first golden rule I should like to see laid down is that form should be the first consideration, and I cannot give a better definition of form than by quoting from Reynolds Hole's charming "Book About Roses," where he says "A show Rose should possess beauty of form—petals abundant and of good substance, regularly and gracefully disposed within a circular symmetrical outline." The next consideration should be colour, which must necessarily include freshness, and the last consideration should be size. That form is, as "WYLD SAVAGE" says, "the great desideratum of a Rose" is forcibly shown in the lovely Marie Baumann as compared with the giant Paul Neyron, the former possessing all three qualifications, the latter possessing colour and size, but wanting form; by comparison wanting everything.

Having tried to show what in my opinion a perfect exhibition Rose should be like, the next point in judging is to find out which stand contains the greatest number of perfect Roses as well as the smallest number of imperfect or weak blooms; this, of course, can be done by counting, and will often decide the matter, but in cases where the numbers are nearly even a more exhaustive scrutiny is necessary, and I think the only satisfactory course to be pursued then is to go carefully over each stand and give points to each bloom—viz., three points to a perfect bloom, two to one not quite so perfect, and one to only a moderately good one. Should the points still remain even the judges must then consider which stand taken as a whole has the freshest colour, the greatest size, and the best foliage, and to do this properly the stands must be placed beside each other in the same light, as a little difference in positions often has a great effect on the appearance of the Roses. Having taken all these points carefully into consideration I think the judges will then be able to make a satisfactory award.

With regard to giving additional points to Tea and Noisette Roses I am sorry to be entirely at variance with "WYLD SAVAGE." If you give them because these varieties are more difficult to grow you must (as a former writer well puts it) extend the same favour to some of the more delicate Hybrid Perpetuals. What can be more lovely than a good bloom of Madame Furtado? and a shyer grower I do not know. On cut-back plants I find it simply impossible to grow it, and yet I suppose no one would think of giving more points to a bloom of that Rose than to one of Charles Lefebvre or Alfred Colomb. Fond as I am of Teas and Noisettes I cannot see any reason why they should have such undue preference; they have a great advantage over Hybrid Perpetuals, inasmuch as they can be shown in classes with them and yet have exclusive classes of their own as well.

Some writer suggests that allowance should be made for the different distances Roses have travelled, but that is simply unfeasible, as judges certainly should not know to whom the different stands belong, and, even if they do, Roses must be judged as they appear at the time of judging; if it turns out that the winner of the first prize lives at the greatest distance (and I have often known such to be the case) all the more honour to him.

There is one other rule which I hope to see made and rigidly enforced, and that is that any duplicate of a Rose shown under another name should disqualify the exhibitor. A duplicate under the same name may be an accident, and I should be disposed to give the exhibitor a chance of replacing it. I have seen prizes given to stands containing more than one duplicate, which the judges probably failed to observe. The blooms of many varieties being very similar their distinctness can only be recognised by their foliage or wood.

Whatever rules may be determined upon by the National Rose Society will, I feel certain, be welcomed by all exhibitors if they tend to ensure what we all earnestly wish—that the best Roses may win.—R. N. G. BAKER, *Heavitree*.

I DO not apologise for joining late in the discussion on Rose judging, in which, and kindred other subjects incidentally cropping up, I take a great interest, because articles, as a rule, in our Rose journal are prone, meteor-like, to disappear too suddenly before their full bearings have been discussed and settled. This happily cannot be said to have been the case with the present series, which has been kept up with great spirit.

As I differ in one at least crucial point from many writers I will venture to give you my view—(1), I object strongly to the National Rose Society issuing through their Committee any code soever of laws in the direction of Rose judges, and I would add as a rider (2), I would not have the names of Rose judges necessarily published as a suggestive piece of advice or warning (as the case might be) before any given exhibition, for the following reasons: Because an honorary secretary (as Mr. Gould pertinently writes), if he knows his work, makes choice of judges who know their work, while, if they do not, no code of laws will fit them for their office. Again, if particular judges have peculiar fancies, I am afraid that, whatever "M. N. R. S." may think to the contrary, no high central authority will have any effect on their decision. The crotchety man will be crotchety still, and so wedded to his opinion as never to consent to be divorced from it. I may be wrong, indeed I sincerely hope I am, but when I see our presidential Mæcenæ cease overlooking fully developed blooms, our controversial Rupert deifying Teas, "H. C." tabulating by point cards, and "C. P. P." making allowances, then, but not before, will I pin my faith on a code of rules for the direction of Rose judges.

Yet this discussion must already have done an immense amount of good, in a quarter, too, most wanted, I mean in helping and guiding many exhibitors and enlightening the public generally. I ask pardon of the latter humbly, but, as an old honorary secretary who has served them well and judged occasionally from the earliest days of the good old Birmingham to the last National Rose Show, I must say that with few exceptions the general public know as little of the comparative merits of a collection of exhibition Roses as they would of a box of Oranges or pen of Southdowns; and it is to the lack of the A B C of Rose lore that the indifference of the public is to be traced towards our beautiful Rose shows, and, as a sad consequence, their hopeless position in an *£ s. d.* point of view.

Viewed in this light I hold an elementary code of rules, intended for general application and circulation (inexpensively with the annual schedule), would be an immense boon to rosarians as a class, while a dogmatic code of rules would either fall as a dead letter in its application to Rose judges, or, if effectual at all, as an apple of discord. Holding such views *Quæta non movere* is the motto of—THE HEREFORDSHIRE INCUMBENT.

NOTES AND GLEANINGS.

THE Hon. and Rev. J. T. Boscawen communicates the following interesting fact on RAISING LILIES FROM SEED:—"Last autumn," remarks Mr. Boscawen, "I let a *Lilium giganteum* shed its seed when green or nearly so, and I have quantities of little plants self-sown well up already. This proves what I have previously said, that if Lily seed is sown before

it is quite ripe it will take but one year instead of two for the seedlings to come up." I have found this was the case with many plants difficult to raise."

— THE Hon. A. Leslie Melville, in confirming the estimate of Mr. David Thomson of the great decorative value of *AZALEA SOUVENIR DU PRINCE ALBERT*, informs us that when he first saw this Azalea in M. Van Houtte's nursery at Ghent some years ago he purchased a small plant for himself, and the finest specimen he could obtain, and sent it to Windsor Castle as a present to Her Majesty. Subsequently on requesting his niece, who was in waiting on Princess Christian, to visit the royal gardens and inspect the plant, the gardener apologised at his inability to show it to her because he had to send the best plant he had to place on the table of the King of the Belgians, who was on a visit at the Castle, and that happened to be the specimen Azalea sent from Ghent. The following year Mr. Melville sent his gardener to Ghent, who related the above circumstance to Mr. Van Houtte. The great horticulturist was so elated that he exclaimed, "The King of the Belgians is my King, who admired the plant sent from here to your Queen. Come in; here is bed and board for you as long as you like to remain at Ghent." We concur in the estimate of Mr. Melville and Mr. D. Thomson that this Azalea is very valuable for decorative purposes. It is semi-double, white, heavily flaked with bright rose, and is distinct both in flowers and foliage.

— AS PLANTS FOR THE ADORNMENT OF ROOMS, either by being placed in windows or occupying vases in corridors, &c., we have not seen any more suitable than the examples of *Dracæna terminalis* which were exhibited at South Kensington last week by Mr. B. S. Williams. The plants in question were splendidly cultivated, for although they were from 2 to 3 feet high and had remarkably stout stems, and the lowermost leaves issuing almost from beneath the soil, the pots in which they were growing did not exceed 5 inches in diameter. The foliage was excellent, the lower leaves being of that bright bronze hue indicative of robust health, the terminal leaves being bright scarlet. The plants were rendered additionally suitable for the purpose alluded to by the healthy carpet of *Lycopodium denticulatum* growing on the surface of the pots.

— THE great value of *CHOROZEMAS* for early spring decoration was strikingly exemplified by the fine specimens staged at the last meeting of the Royal Horticultural Society by Messrs. Standish & Co. of Ascot. The plants referred to were not remarkable for their great size so much as for their general health, condition, and excellent training. They were somewhat oval-shaped and about 2½ feet in diameter. The foliage was of the richest green, and the flowering sprays were not closely tied to a trellis, but were sufficiently free to display their natural elegance. The species was *C. ilicifolia*. We recently observed in the nursery of Messrs. Carter & Co. at Forest Hill some small plants in 4 and 5-inch pots of *C. varia grandiflora*, which were flowering freely. Such plants are not only valuable for general decorative purposes, but afford sprays for cutting as bright as they are elegant. *Chorozemas*, owing to their ready growth and free-flowering properties, are eminently worthy of the attention of cultivators for spring and summer decoration.

— WE have received a copy of the eighth edition of "CARTER'S PRACTICAL GARDENER," and, to quote from the letter accompanying it, "since the sale of this work has now reached the large number of forty thousand copies we do not consider any further recommendation is required." We may observe that this success is a proof that the public can appreciate what is useful and practical, and that excessive adornment and unmeaning display, which while they may "catch the eye" of a peripatetic public, are not essential to secure the support of discriminating readers, whose object is to obtain information to aid them in making their gardens profitable and pleasurable. We predict that of "Carter's Practical Gardener" still further editions will be required, and we think that a book so serviceable in its nature and varied in its subjects is worthy of an index or a table of contents.

— A SMALL volume, entitled "POTATO PESTS," has been published at New York by Dr. Riley. It relates to several insects which prey upon the Potato, but principally to the Colorado beetle.

— A CORRESPONDENT in referring to the rapid GROWTH OF LONDON states that a large portion of the land that Messrs. Bagley have so long and successfully cultivated at Fulham as market gardens is being converted into brick fields, and that

the firm have secured 150 acres of land in the neighbourhood of South Fields, Wandsworth, for the cultivation of vegetables. Our correspondent observes that in a few years all the market gardens of Fulham will be built over. There are some hundreds of houses in contemplation at the present time, which must necessarily drive cultivators further away from the metropolis.

— IN order to render intelligible the award of a cultural commendation which the Floral Committee of the Royal Horticultural Society awarded to Mr. Johnson on the 19th inst. for plants of *DAPHNE INDICA RUBRA*, it is necessary to say that the plants were only five years old, yet were close pyramids about 18 inches in diameter at the base, and 2 feet high. The foliage was large, glossy, and of a dark green colour, and the flowers were numerous and fine. Considering that this is proverbially a slow-growing plant, the specimens exhibited well merited the mark of recognition accorded. When thus well grown this good greenhouse plant is highly attractive, and its powerful yet delicious fragrance imparts an additional charm to an old favourite which well repays for any skill bestowed upon it by its cultivator.

— THE round beds in the central transept of the CRYSTAL PALACE are now very gay with bulbs and forced flowers, such as are generally employed for decoration at this period of the year. But a plant which is not by any means so commonly met with as its merits deserve, and which shows to much advantage associated with the other flowers, is *Begonia manicata*. The tall flower spikes of this *Begonia* and the cloud of delicately-tinted miniature flowers not only contrast effectively with the large foliage of the plant, but, as rising above the more massive flowers with richer colours, enhances the beauty of a floral group. The plants are found to continue in beauty for a considerable time in the moderate temperature of the Palace. They require, however, being grown in a warmer house until the flowers commence expanding. It may be observed that unless this *Begonia* is well grown its effect is unsatisfactory, but when it receives correct and generous treatment it invariably commands a large share of appreciation.

— BY a clerical error Brown's *Exquisita Primula* as flowering in Messrs. Carter's nursery at Perry Hill was described on page 149 as being rosy purple in colour. Its colour is a bright magenta crimson with a yellow eye. The flower is large and of good substance. It is one of the brightest and best of *Primulas*.

— A MOST successful instance of flowering the *EUCHARIS AMAZONICA* in a pot is to be seen in the gardens of J. Boustead, Esq., Wimbledon. Year after year this plant becomes more floriferous, while it retains its exuberant growth of foliage. This plant fills a No. 2 or 18-inch pot, and its diameter through the foliage measures from 5 to 6 feet, and as a rule bears three crops of flowers annually. During April and May last year the plant had twenty-eight flower spikes, in the following September forty-two flower spikes, and during last month forty more, making a total of 110 flower spikes within the year, which is equivalent to 550 single blooms, and the last batch of flowers were even of larger size and stronger than the blooms that appeared in the summer, no spike having less than five flowers. Mr. Jordan would do good service by detailing his successful mode of culture of this much-prized flower.

— THE Société Centrale d'Apiculture et d'Insectologie has had constructed a pavilion in the Champ de Mars for the purpose of exhibiting in 1878, in the most complete manner, everything relating to the education of USEFUL INSECTS, especially bees, and the means of preservation of all kinds against noxious insects.

— ALLUDING to *BEGONIAS* AS WINDOW PLANTS as mentioned on page 102, an amateur speaks approvingly of B. SAUNDERSII SEMPERFLORENS. This *Begonia*, he says, is one of the most valuable because of its dwarf habit, its shining foliage, and its great freedom and long-continuing flowering properties. The flowers are white, and being erect and arranged in close heads at the extremities of the shoots are well adapted for bouquets. Our correspondent recommends this *Begonia* not for window decoration only, but also for conservatories large and small. "It should be cultivated," he says, "wherever attractive decorative plants are required, and where cut flowers are cherished."

— A CORRESPONDENT ("EDAX") states that SPARMANNIA AFRICANA merits all that was said about it on page 91, and is worthy of much more extensive cultivation.

than it receives at the present. He is of opinion that it is not the seldom-seen-and-uncared-for plant that has been represented, but is to be found in many places where fine old-fashioned plants are cared for and the cultivator has not quite devoted all his attention to the red, white, and blue. "EDAX" has seen the *Sparmannia* in the north of England cherished as an heirloom in many cottage homes, and hopes with "J. P." to hear still more of this fine old plant, which forty years ago was cultivated as a choice stove plant.

— WE have had intimation from several districts that WINTER CUCUMBERS have not been satisfactory during the present winter, and we have had more than the usual number of inquiries relative to unhealthy plants. The cause of failure is perhaps attributable to the great prevalence of dull weather. Gardeners can supply artificial heat in clear cold weather, but they cannot obtain the light that is necessary to grow Cucumbers well when clouds prevail over a long period during December and January. Failures, especially during a dull season, frequently occur also from the plants having been raised too late in the autumn. We have observed that where the crops have been good throughout the present winter the seed was sown towards the end of July, and a strong growth was made before the dark days and long nights of winter.

— ALLUSION has recently been made to the practice of SHADING CAMELLIAS. Some of the most healthy Camellias, writes a correspondent, that he has seen are in the Royal Gardens, Windsor, "in a very light house facing the south, and yet the plants are seldom if ever shaded." A plant of *C. reticulata* growing in a brick pit at Chiswick, with its foliage trained close to the glass and facing due south, is never shaded, and the leaves are quite fresh and healthy. "AN OLD GROWER" states that much of the scorching of Camellias is due to an insufficient supply of water during the growing season. If the plants are thoroughly watered, he says, to prevent the young growths flagging, the leaves are seldom seriously disfigured by scorching. The safe course to adopt is probably to water copiously yet judiciously, and to shade intelligently.

— WE have received from Messrs. James Fussell, Sons, and Co., Mells Iron Works, Frome, a short treatise on SCYTHES AND MOWING. The history and manufacture of the implement are referred to, and the various uses to which the scythe has been applied are noticed, also the fixing and sharpening of the blade are detailed and illustrated by several engravings. These figures become the more necessary because, owing to the general employment of the mowing machine, the majority of young gardeners possess little or no practical acquaintance with the scythe, but who may nevertheless be called upon to use it, for, as is suggested by the treatise, there are thousands of hilly lawns and knolls where the mowing machine cannot be worked which must continue to be kept close by the scythe, and a knowledge of this old implement is therefore essential to all gardeners.

THE ROYAL GARDENS, KEW.

THERE has lately been a good deal of agitation among the inhabitants of Richmond and Kew about opening Kew Garden as a public recreation ground from ten in the morning instead of from one, as it is at present. Like most agitations of a local character and of no great moment it has been conducted with the usual amount of noise. Meetings have been held and deputations have waited on the First Commissioner of Works; flowers of local oratory have been cultivated, and the "rights of the people" have been asserted, as they always are when a small section of the community wants to appropriate public property for their own benefit. The only argument we have heard in favour of this movement is that some speculating builders having succeeded in forming a neighbourhood along the road between Kew and Richmond, the inhabitants who have become possessed of these houses are endeavouring to increase their value by adventitious means, and these are to urge the Government to open the Royal Botanic Garden of Kew from morning till night, that these people and their domestics may disport themselves at the national expense. Such a proposition, even at first sight, seems monstrous, and when it comes to be investigated one cannot but be surprised at the presumption which these people are capable of.

To convert the Royal Botanic Garden of Kew, the most renowned in the world, into a public recreation ground for the population of a great city like London, would at once be a prostitution of the use and object for which it was founded,

and a serious obstacle to the advancement of that science which has been there fostered for upwards of a century with results so brilliant. Such a thing is not required by the inhabitants of London. They are already provided with parks in all directions within convenient distances of their homes; and on ordinary occasions when they want to go the country there are plenty of places, such as Epping Forest, Hampton Court, Bushey Park, and Richmond, where the nation has provided them with space enough for recreation. But it is not for the benefit of the masses of London that this movement is now set on foot; it is for the languishing populations of Kew and Richmond, which are already so amply provided for. Kew Green, with its beautiful turf, well-kept paths, and shady trees, under which are convenient resting places, is surely enough for all the requirements of the inhabitants of the Royal village, of whom there are not so many; and Richmond Park may well satisfy the people of Richmond. What need, then, is there for the opening of the Royal Botanic Garden as a recreation ground, which was founded for totally different purposes, and which is maintained by the nation with a totally different object?

Supposing such a thing were unfortunately to happen that the national collection were to be opened to the public all day long, the staff, whose present employment is to be one half the day engaged in their legitimate work and the other half caretakers, would require to be all day care-takers, while another set was required to attend to the cultivation and management of the establishment. It is known by experience that grounds like those at Kew, beautiful as they are, have not yet had the soothing and humanising effect on the British rough that optimists think they have. Lord Stamford found that at Enville, and has been obliged to close his beautiful grounds altogether. If, then, a great additional outlay is to be incurred so as to secure that proper care be taken of the valuable national property at Kew, is it to be tolerated that the people of Great Britain are to be taxed to this extent that the handful of people who live on the Richmond road and their nursemaids may have three hours longer use of the Botanic Garden than they have now? It is too absurd to be thought of, and we hope that the First Commissioner of Works will not be induced to divert from their legitimate use the unrivalled national collection so that a few of the local inhabitants may be relieved of what they have talked themselves into considering a grievance. It becomes all who are interested in the advancement and the protection of scientific inquiry throughout the country to raise their voices against this mis-appropriation.

FRUIT TREES IN PLEASURE GROUNDS.

"AMATEUR, Cirencester," in speaking approvingly of Mr. Cole's suggestion of combining beauty with utility by planting fruit trees in pleasure grounds, has through the Editors requested further particulars respecting the combination of evergreens and fruit trees recorded on page 65. I have been unable to attend sooner to the letter of request which has been forwarded to me, and while I can answer the questions that "AMATEUR" has submitted, I am not certain that I can make the mode of planting intelligible. I will, however, try to do so.

The combined fruit and shrub garden does not exceed an acre in extent, and is irregular in form. The ground was first trenched quite 18 inches deep, and the trees and shrubs were planted in a small state from 4 to 5 feet apart, but eventually half of them were removed and planted in other positions, so that the fruit trees and evergreens in the garden alluded to are now on an average about 9 feet apart. The fruit trees now range from 5 to 8 feet in height, according as they have been pruned as bushes or pyramids, and there is ample room to pass amongst them for pruning and gathering the fruit. At the back of the enclosure fruit trees preponderate, and they diminish in numbers towards the front, which is planted wholly with evergreens and a few flowers.

The subject can be made more plain and the example more easy to be worked from by supposing the garden is formed into a square and the trees and shrubs are planted in straight rows. In that case the position is as follows:—At the extreme back a belt of Laurels form the boundary: the Laurels next the fruit trees are slightly pruned to keep them "within bounds," but they grow upright as high as they like or can. At the front of the Laurels and 6 or 8 feet from them comes an entire row of *Beurré de Capiaumont* Pear, which is compact in growth and forms natural pyramids. The next row is of *Victoria Plum* and shrubs alternately, the latter consisting of green

Hollies, Yews, and Arbor-Vitæ, which require little pruning, but they are pruned as is found necessary. Then comes another row similarly planted, but the fruit trees are Cellini Apples; and in front of this again are shrubs and dwarfed Apples, Cox's Orange Pippin. The next row has twice the number of evergreens that it has fruit trees, then come two rows of shrubs more closely planted, which brings us to the flower border. The shrubs employed are mostly of close upright growth, such as Thujas, Hollies, Irish Yews, Arbor-Vitæ, and Junipers, the front rows having greater variety, including Box, Aucubas, and Golden Queen Hollies.

Such is the principle that was adopted and which can be carried out with such modifications as are necessary in a shrubbery of any shape or size. The fruit trees have succeeded excellently, and certainly the garden is not less admired because of their presence amongst the evergreens in such large numbers.

A chief cause contributing to the success of the combination is that the ground was well prepared; and perhaps not of less importance was it that the fruit trees and evergreens were all planted at the same time. Probably were fruit trees planted in an established shrubbery with the soil already permeated by the roots of shrubs that the trees would not grow nearly so well; but when all are planted at the same time and have the same chance of occupying the ground with their roots there is no real danger that the evergreens will injure the fruit trees by appropriating the "lion's share" of support.—A SQUIRE'S GARDENER.

EARLY PEAS.

YOUR correspondent Mr. Campbell adopts the right way of growing Peas early. They require no nets, no boxes, no glass, which for young early Peas is a delusion. For a dozen years here I have grown them *à la* Campbell, and they have always done well. Just now my First Crop, Ringleader, and William I. are about from 3 to 4 inches high, hardy and strong, without any protection whatever. My first border (south) is about 100 feet by 10. I find by having a quantity to pick from early, if only a dozen pods are ready in each row, I can gather a dish many days earlier. I also grow Little Gem in the Cherry house in boxes, and gather from them about the middle of April generally. These, if closely picked and well watered, last for a long time, and very useful they are.—AN OCCASIONAL CORRESPONDENT.

RASPBERRIES

PROVIDED Raspberries are planted in deep and well prepared soil, and have proper attention both in summer and winter, I think they will succeed on the same plot of ground as long as will any other crop. I have had in my care a bed of Raspberries that was known to be upwards of fifty years old, and better crops of fruit I never gathered than from that bed. In summer the young shoots which clustered around the stools were thinned out when about 6 inches high instead of being left, as they too often are, to form a dense thicket during the summer, only to be thinned out in the winter. The ground between the rows was very slightly pointed over with a fork, and manure, and occasionally a slight sprinkling of soil, was spread on the surface annually; also, as the district is a dry one, a liberal dressing of salt was applied to the ground in April. The old stools under that treatment produce canes 6 feet in length, which are quite as fruitful as canes in another plantation which is only five years old. But while I consider that Raspberries receiving good cultural attention will occupy ground profitably throughout the lifetime of the cultivator, I should still consider it prudent in making a new plantation to select ground that had been occupied by some other crop. It is by permitting the young growths to be excessively crowded during summer and mutilating the roots by deep digging in the winter that makes the ground miscalled "Raspberry sick," but the Raspberries are not so much sick of the ground as of the unnatural treatment to which they are not unfrequently subjected. The beds of wild Raspberries to which "WILTSHIRE RECTOR" has alluded are probably older than the rector, and I think it would not be difficult to find evidence that natural plantations of Raspberries which now yield fruit plentifully are centenarians.

Every cottager who has ground space at his disposal should grow Raspberries, and if he has not stakes nor wire for supporting the canes they may safely be left to support them-

selves. It is to be feared that a lack of stakes, &c., is a great impediment to Raspberry cultivation, and yet more Rasps are produced without the aid of stakes or wires than with them. If the young growths are timely and sufficiently thinned during early summer the canes become sufficiently sturdy to carry all the fruit they can produce and to resist the effects of the most boisterous winds.

A few years ago I obtained canes of all the sorts grown in Mr. Pearson's nursery at Chilwell for the purpose of testing the merits of the different varieties. After several years of trial I reduced them to the three following, which are placed in the order of merit:—1, Carter's Prolific; 2, Northumberland Fillbasket; 3, Fastolf.

I esteem the first-named the most serviceable variety in cultivation, and I am surprised to find that it is not mentioned in the new edition of Thompson's "Gardeners' Assistant." It is not by any means a new variety, but is so well established that it is grown by the acre in Kent, and is, I am informed, one of the most profitable of the sorts grown there for market purposes.—A MIDLAND-COUNTIES FRUIT-GROWER.

MY own experience of growing Raspberries leads me to think that "WILTSHIRE RECTOR" is wrong in saying that ground becomes Raspberry-sick, and that hence they must not be grown too long in the same place. Mine have been grown in the same quarter for thirty-five years, and yet we always have an abundant crop of splendid fruit.—R. N. G. BAKER.

IRISH YEW.

IN your answers to correspondents, in reply to "COUNTRY VICAR," you state Irish Yews may be raised from seed. I have sown berries of the Irish Yew, and although the seedlings were of more upright growth than the common Yew, none approached the form of the Irish Yew. The original Irish Yew is, according to Loudon, a female plant, and I presume all which are descended from it will be females, having their flowers impregnated by male flowers on plants of the common Yew or other varieties.—G. C. S.

PELARGONIUM ECHINATUM.

SINCE Zonal Pelargoniums have of late years absorbed such a large share of attention some of the less gorgeous species have been comparatively neglected. A plant nowadays to meet with favour at the hands of general cultivators must be of quick and easy growth and be capable of making an imposing display, or must otherwise be adapted for some particular decorative purpose: in a word, it must serve some really useful and practical end or it is cast aside to make room for others of greater popularity. Thus have many dainty gems of the floral world been pushed off the stage in favour of something more utilitarian in its nature and more commanding in its appearance. It is not necessary to say one word against Zonal Pelargoniums. They have probably done more to make English homes and gardens bright and beautiful in summer than have any other plants; and they, as every year's experience more fully proves, are almost equally adaptable for contributing of their beauty in greenhouses, &c., in winter. Let them be grown in all their massiveness of truss and great variety of colour, but let some others of the genus be grown as well as they. Others are grown. Those beautiful varieties known as Show and Fancy Pelargoniums will always assert their claims to cultivation and will command attention; it is not necessary, therefore, to urge their acquisition.

But there are Pelargoniums less frequently seen than those above alluded to, and which are not only distinct and attractive, but which are really serviceable. Of such is the species figured—*Pelargonium echinatum*. For affording charming cut flowers during the winter months this species is particularly valuable. Its clear tall flower stalk and pleasing and delicately coloured truss render this species almost indispensable where flowers for bouquets and vases are cherished during the late autumn and winter months. It is only in comparatively few gardens where this attractive Pelargonium is cultivated; but that its value is becoming more generally recognised is found by the increasing demand for plants. As an instance of the rising popularity of *P. echinatum* and its varieties Mr. Cannell has found it necessary to encourage the growth of his large stock, and to sacrifice the flowers in order to increase the number of cuttings and to establish young plants.

Unlike the Zonal and Show Pelargoniums, which are usually

increased by inserting cuttings in autumn, *P. echinatum* must be struck early in spring; the plants have then time to form growth during the early summer months, and to enjoy a natural period of rest in late summer preparatory to flowering during the dull period of the year. To cut down and attempt to strike this species in the autumn would be tantamount to

cutting off the young growths from Show Pelargoniums in March and then to expect the old plants to flower freely in May; the present, therefore, is an excellent time for propagating plants of *P. echinatum*. The cuttings may be struck in heat and the plants be grown-on similar to Zonal Pelargoniums—that is, be placed on shelves near the glass in a light

Fig. 26.—*PELARGONIUM ECHINATUM*.

house having a genial temperature, afterwards removing them to frames, and eventually placing them in the open air. They will cease growing during the hot days of summer, but in the autumn will start the stronger for their short period of rest. When this autumn growth commences the plants should be repotted by shaking most of the old soil from their roots and placing them in the same sized pots, when a rich compost being employed, and a moderately heated and light structure being provided, they will produce trusses of bloom throughout

the winter that cannot fail being appreciated for bouquets and for vase decoration.

Besides the species, which has pearly white flowers feathered and spotted with maroon on the upper petals, two darker varieties of great beauty have been raised by Mr. Sampson and are being distributed by Mr. Cannell—namely, Spotted Gem (which has received a first-class certificate), rosy magenta spotted and striped with dark crimson; and Rosy Morn, rosy violet shaded with carmine and spotted and feathered

with crimson. *P. echinatum* was introduced from the Cape of Good Hope in 1789, and received its specific name on account of the hooked spines which form on its stem apparently in the place of stipules.

STEAMING AND DAMPING VINES—HIGH TEMPERATURES.

[It seems to me that if we could discuss such questions as this from some common standpoint it would greatly aid us in our investigations, and help us to remove many questions that gardeners have been wrangling over for years out of the region of doubt and speculation. It is hardly likely that we shall convince each other by simply recording our own opinions, which may or may not be based upon false premises, notwithstanding apparently corroborative experience which no one would perhaps gainsay, while doubting the conclusions drawn from it.

With regard to the subject which heads this letter, I suppose we are all agreed that that treatment which secures the best and most permanent state of health and fertility in the Vine is the best for everybody to practise. The question, then, is first, What is the best state of health? and secondly, What kind of treatment is most likely to secure it? Is good health and sturdy vigour denoted by broad flabby leaves and attenuated long-jointed wood, or by leaves of moderate size but otherwise well developed, of good colour and substance, and short-jointed wood and plump buds? If by the first, then the correct treatment as dictated by everyday experience would be high artificial temperatures and a steaming atmosphere; if by the second, moderate temperatures and a rather dry atmosphere, with freer ventilation. I am not sure that I have stated the case in a perfectly clear and intelligible manner; but when I first began to experiment in this matter I put the question to myself something after the above form, and I need hardly say that both reason and experience led me to the conclusion that the low night temperature and comparatively dry atmosphere system was the best under the exceptional conditions which the Vine is subjected to under glass in this country; and though I have both read and heard much discussion on the subject since, my conviction has not been in the least shaken, but rather confirmed.

Hot-water pipes are simply a necessary evil, as is proved by the everyday practice of steaming and damping to correct their ill effects, which practice has become engrafted in the Vine-growers' creed, its origin having so far been lost sight of. Hence many young practitioners have no reason or explanation to offer for it—they just continue it as a matter of course because they have been taught to practise. One phase of the question really is, Whether shall we continue to keep up high night temperatures by means of hot pipes, and steam and damp to prevent the same from doing injury, or do with lower temperatures and less fuel, and obviate the necessity of so much steaming and damping? It looks an absurd question to put, but it is just what it amounts to. It is not a question of a gardener here and there producing fine Grapes by either plan. We know that plants will submit without apparent injury for a time to unsuitable treatment, but to those who point to their fine examples produced under the high temperature and damping system I would say, You have produced them by your good management in other respects, and not in consequence but in spite of the steaming and damping which you have subjected your Vines to.

As regards my own practice, I never damp our vineries except when they are shut up to economise sun heat, and then it is necessary to prevent scorching; but the weather I prefer is balmy dry summer weather, when we can throw the vineries wide open and leave them open night and day without fire heat and without damping of any kind. Supposing such conditions to be most favourable to the Vine, can the other extreme be right?—J. S. W.

NOTES ON NORTH DURHAM AND NORTHUMBRIAN AMATEURS AND FLORISTS.—No. 1.

PANSIES.

In general north-country amateurs and florists are scarcely known or heard of beyond their limited range of local acquaintances, yet many of them are men of horticultural calibre and skill; and perhaps their feats may have seldom been chronicled in any horticultural periodical, nevertheless they would rank with amateurs of perhaps more favoured districts.

Many of them are generally plodding men of industry, who work from early morn to sunset, and let it be said to the credit of the pitmen also, that several of them are as fond of flowers as they are supposed to be of their collic dogs. It is a consoling fact, and I believe one that has its advantages on society at large, that if the poor plebeian once turns his mind to the study of Nature in the forms of her simplest flowers, the effect on him and his locality will be highly beneficial, and that local flower shows are the means of promoting and developing this taste is beyond doubt.

The subject of these notes, Mr. Thomas Battensby, Hag Hill, Axwell Park, Blaydon-on-Tyne, is a carpenter by trade, and at present clerk of the works of the Axwell Park estate. He is a real specimen of the intelligent industrious amateur, and as such made his *début* in the horticultural arena in the cultivation of the Pansy some twenty years ago. Inheriting an innate love of and thirst for knowledge, his ideas soon led him into more lofty aspirations, and perhaps no amateur is more deserving of the cognomen "practical" than he is. Whether it be as a florist, a grower of vegetables, or a cultivator of plants, his name has ever formed an important figure at all shows betwixt Bishop Auckland and Alnwick; but in the cultivation of the Pansy and *Gladiolus* he has been very successful, especially in the former; in fact, he has never been beaten, and he has also raised many show flowers.

CULTIVATION OF THE PANSY.—Mr. Battensby's mode is as follows:—He prefers good, light, retentive soil, and the manure old hotbed dung, or else old decomposed cow manure, which he thinks is better still, to be spread about 3 or 4 inches deep, and the ground dug about two spits deep early in the season, and afterwards forked over five or six times during the winter. This he considers of paramount importance, as it causes the soil and manure to be thoroughly incorporated, and also gives the soil the full benefit of the atmosphere, believing also it is valuable in checking or destroying that dire enemy of the Pansy the wireworm. Mr. Battensby generally commences planting his Pansies about the beginning of April in beds 2 feet wide with alleys between them, enabling the plants being easily attended to. The plants are placed a foot apart in the bed. He allows about four shoots to each plant, and one flower to each shoot. He mulches the surface of the beds with horse droppings, which he considers prevents the movements of slugs, and waters the plants with diluted urine and soapsuds. This he uses two or three times a week, to which is added a little soot for the sake of imparting colour. He syringes the plants frequently on the evenings of sunny days. He is a successful hybridiser, the flower to be hybridised being covered with glass; each class of colour is kept separate, and the best flowers on the strongest plants are selected for crossing and seeding.

As regards insects, green fly he suffers but little from, as he finds they seldom attack plants in robust health. For slugs he keeps a sharp look-out after dark. Wireworms are also sedulously watched for: on the first appearance of the slightest flagging he at once resorts to a searching investigation at the roots, and generally finds the enemy concealed about an inch below the surface. He only shades his flowers in case of rain, and generally uses glass with a current of air underneath.

He is an advocate for Pansies being shown on boards or green stands, each flower being placed upon a piece of white card. For spring planting he does not take off the cuttings before October, preparing a cold frame by digging-out the natural soil for about 1 foot, and filling-up with good sifted loam, leaf soil, and sand. For blooming early he takes off the cuttings early in the summer, and after they are struck plants them in the beds in September. He never grows his Pansies two years in the same piece of ground.

The following are a few of the flowers which he has raised; they are all show varieties, for he is not an ardent admirer of fancies:—Lady Hutt, white self colour; Robert Scott, dark purple; Elizabeth (good), white ground and purple belt; J. C. Murray, yellow ground and bronze belt; Miss Clavering, pure white (good); Mrs. Adams, a cream self; Sir Henry A. Clavering, Bart., yellow (best yellow). In addition to these he also has about two dozen seedlings to name. He also grows the following flowers of other raisers:—

Selfs—Robert Black, dark purple; Locomotive, dark; Robt. Scott, purple self; Lady Hutt, white; Thos. Cassells, cream; Sir Robert Napier, black self; Mrs. Knight, and Miss Muir. *White Grounds*—Miss E. Cochrane, Miss Adamson, Sunny Park Beauty, Miss Ira Clark, Mrs. R. B. Matthews, Miss Bessie McAslan, Lady Lucy Dundas, and Miss Todd. *Yellow*

Grounds.—J. B. Downie, Defoe, Robert Burns, Normand, Perfection, Novelty (Hooper), J. C. Murray, and Mrs. Russell.

I will next refer to Mr. Battensby's mode of cultivating the *Gladiolus*.—B. C.

NEW PLANTS AND FLOWERS.

BILLBERGIA PALLESCENS. *Nat. ord.*, Bromeliaceæ. *Linn.*, Hexandria Monogynia.—“It was introduced more than twenty years ago from Central Brazil by M. Libon. A specimen flowered in the Kew collection last November.”—(*Bot. Mag.*, t. 6342.)

IRIS CRETENSIS. *Nat. ord.*, Iridaceæ. *Linn.*, Triandria Monogynia.—“This pretty little Iris has a wide distribution round the eastern shores of the Mediterranean, as it occurs in Greece, Asia Minor, Crete (where it ascends the hills to 5000 feet above sea level), and the Ionian Islands. It has been confounded with the South Russian and Transylvanian humilis and the Algerian unguicularis, but is quite distinct from both, and the three inhabit different geographical areas.”—(*Ibid.*, t. 6343.)

IONE PALEACEA. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monogynia.—Native of Upper Assam. “There are two other Mishmi species of Ione described by Griffith and Lindley, and there is also a Sikkim one (*I. cirrhata*, *Lindl.*), found by Dr. Hooker, which has oblong leaves and very differently formed sepals, resembling the rude drawing of Griffith more than that of *I. paleacea*. Our plant was received from Dr. King of the Calcutta Botanic Gardens, and flowered in October of last year at Kew.”—(*Ibid.*, t. 6344.)

PLEBOMA GAYANUM. *Nat. ord.*, Melastomaceæ. *Linn.*, Decandria Monogynia.—“*Pleroma Gayanum* is one of the least conspicuous of the genus. It is a native of Cuzco, in Peru, where it was discovered by the French botanist and traveller, Claude Gay, and has been since collected by Lechler. The plant here figured was imported by Messrs. Veitch through their collector Mr. Davies, and flowered with them in October, 1874.”—(*Ibid.*, t. 6345.)

CROSSANDRA GUINEENSIS. *Nat. ord.*, Acanthaceæ. *Linn.*, Diandra Monogynia.—“This charming plant was described by Nees von Esenbeck, forty years ago, from dried specimens in the Hookerian herbarium received from the coast of Guinea, but from which the beauty of its foliage could not be inferred. Since then it has been collected by that most successful of all travellers on the Guinea coast, Gustav Mann, who found it in the mountainous region of the island of Fernando Po, at an elevation of 2000 feet, and in the Sierra del Crystal range, in lat. 1° N., in 1862.”—(*Ibid.*, t. 6346.)

PANDANUS UNGUIFER. *Nat. ord.*, Pandanaceæ. *Linn.*, Dicoelia Monandria.—Drs. Thomson and Hooker found this species in Sikkim, from the Terai up towards Kursiong to about 3000 feet; and in the Khasia Mountains at Joowye about 4000 feet; and at Nowgong, and plentifully elsewhere in those regions. Sikkim plants sent to Kew by the late Dr. Anderson when superintendent of the Calcutta Botanic Gardens first fruited in July, 1873.—(*Ibid.*, t. 6347.)

GARDEN ENEMIES.

WHATEVER differences of opinion may exist as to the value of small birds, snails, grubs, and caterpillars can have few defenders. These are admitted garden enemies, and much trouble is caused and loss experienced by their nocturnal expeditions. Various means are recommended for destroying slugs, &c., but those who have had the most experience in battling with those voracious and almost ubiquitous garden pests generally arrive at the conclusion that the old plan of “catching and killing them” is the most effectual for saving the crops, hence hand-picking of caterpillars, &c., is recommended by most practical men as being the most satisfactory means of eradicating the pests in question. But hand-picking of slugs, while not being objected to by garden labourers and boys, is naturally regarded as repulsive by those amateurs who have to rely on their own hands for preserving their flowers and vegetables from destruction by grubs and molluscs. To such cultivators the little implement figured would be very acceptable. It is so simple that no difficulty can be experienced in the making of it, and that it answers its purpose well we have had sufficient experience. The grub-picker is 7 inches in length, and is made of iron wire about three-sixteenths of an inch in diameter, bent and rivetted as shown in fig. 27. The points are formed of two triangular-shaped

pieces of sheet copper about 1½ inch in diameter at the base and soldered to the ends of the wire, which are flattened for that purpose. The points of the triangles are slightly rounded, which enables them to be used more freely amongst the stems of plants.

Fig. 27.—The Grub-picker.

As the spring is approaching, and with it those garden enemies that cause such injury and not unfrequently total ruin to valuable and cherished crops of young seedlings, the time is not inopportune for introducing a simple implement which, if it does not render grub-picking pleasurable, enables that necessary work being performed with cleanliness and expedition.]

FERMENTING MANURE ON VINE BORDERS.

“FERMENTING manure and leaves promote the formation of roots near the surface of Vine borders” are the words given on page 74 in reply to a correspondent, and it is further remarked that “the practice is a good one if properly carried out.” Undoubtedly it is, and the obverse is equally true—that the practice is a bad one if it is improperly carried out. Much good and much harm has been done by placing hot manure upon Vine borders: good when placed on at the right time and of the right temperature; harm when it has been placed on too soon, kept too hot, or removed injudiciously. Most gardeners have made mistakes at some time during their practice, especially those who have been zealous in their calling, and such men generally become successful sooner or later. It has been said that the man who has made no mistakes is not likely to have made many experiments, but has been content to follow the beaten path of steady mediocrity. This is a safe course no doubt, but now-a-days the ambition of a gardener must be to pass the “steady mediocrity” stage, or he will be left behind in the keen race where the competitors so greatly preponderate over the prizes to be won.

In no practice of gardening has greater advance been made during the past quarter of a century than has been accomplished in Grape-growing. During that period not only have the greatest crops and the heaviest individual bunches been produced, but the practice has been established of having Grapes “all the year round.” The achievements of successful cultivators have been recorded by the horticultural press, and a stimulus has thus been given to young men to excel in that which is now regarded as about the most important phase of their calling—the art of Grape culture.

It is more than twenty years since I was first impelled to "go ahead" in Grape-growing, and soon after I commenced I made a mistake. Grapes were wanted in May, and by way of "giving them a good start" I covered the border thickly with hot manure almost as soon as the rods were pruned in November. The manure was placed on the roots too soon; for although fresh roots formed freely enough, covered the surface of the borders, and penetrated the manure, yet the Vines broke weakly, and the crop was a miserable failure. I was perplexed, and in my trouble took counsel of an old and intelligent practitioner, who told me, in terms that I shall not soon forget, that I had "drawn the life out of the rods." This, if true, was the "descent of sap" with a vengeance, for he asserted, and I have never been able to contradict him, that the sap stored in the rods for commencing the formation of fresh shoots was drawn downwards and spent in the extension of roots. From that time to this I have never placed heating material on the roots until after the vineries have been kept close and the eyes have shown signs of swelling. I have never had a failure since adopting that practice; but I have seen one. Some years ago I witnessed hot manure being piled on a Vine border in the autumn. I ventured to point out the possibility of a mistake being committed, but received a "mind your own business" sort of reply. The placing-on of the manure was a mistake nevertheless, for the Vines were half killed, and their manager went half crazed. The injury in that case did not result by "drawing the sap" out of the Vines, but was a simple case of first extreme heat having been applied to the roots, and as soon as the error was seen a rushing to the other extreme and removing the manure; indeed, to use a plain term which scarcely exaggerates the case, the roots were first roasted and then frozen. The Vines, as may be supposed, were permanently injured.

Many gardeners who are unable to obtain fermenting material for covering the Vine border look on those who have such fine "heating stuff" with envious eyes. Except when Grapes are wanted at the end of May or during the first days of June it is really unnecessary to cover outside Vine borders with hot dung and leaves. For ripening Grapes in July I have found, after thirty years of experience, that the fermenting material can be very well dispensed with. Instead of applying a hot covering in spring to drive the heat downwards into the border I have found greater benefit result by covering them very early in the autumn, before the sun heat has escaped from them, with a good layer of rich half-decayed manure, and there letting it remain to supply nourishment to the roots and to decay and form a layer of rich soil. I think the value of applying fermenting material to the surfaces of Vine borders is over-estimated, and I am sure it can both be applied too soon and removed too soon. On the other hand I have experienced the benefit of the practice, but under circumstances which I cannot detail now.—YORKSHIREMAN.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Old garden ground that has been long under cropping will be improved by an application of lime, especially land that has been heavily manured and which it is intended to plant with Potatoes. Lime acts as a corrective of an excess of decaying vegetable or animal substances, and in its quick state is very fatal to slugs and obnoxious to a variety of grubs. We advise, therefore, an application at the rate of eighty bushels per acre now, or so soon as the ground is in good working order. We are particular to apply it in dry weather, spreading it equally over the surface whilst fresh, pointing it in at once with a fork. In the case of large plots harrowing will embed the lime sufficiently deep. An application of this kind need not be made oftener than every third year. Ground containing much vegetable matter, as that recently taken in from pasture, is beneficially acted upon by lime, but in no instance should manure and lime be applied at the same time; therefore our remarks apply to ground which was well manured in the autumn and to such as is rich in organic manures, which require liberating to render them available as food for plants.

Cauliflowers wintered in frames which have been injured to the weather as previously advised may have the strongest plants transferred to handlights, four or five plants being placed under 2-feet lights; or they may be planted out on a warm border 2 feet apart and 18 inches asunder in the rows, having protection in case of severe frost. This will afford more room to those remaining in the frame. Those under handlights should be thinned and have the soil stirred about them to encourage growth, giving them also a sprinkling of soot. Parsley sow in drills 18 inches apart, or if for transplanting it may be sown broadcast, which is desirable

in soils where the crop is subject to canker. The new Fern-leaved is very fine for garnishing. An open yet sheltered situation should be chosen. Have all vacant ground as it becomes cleared of the crops manured and dug or trenched preparatory for others, and ply the hoe frequently between the rows of growing crops, maintaining neatness by clearing away weeds and decayed leaves from Broccoli, Greens, &c.

FLOWER GARDEN.

The ground amongst shrubs should now be lightly forked over, but only sufficiently deep to impart a fresh appearance and to bury any small weeds. Weeds of a perennial tap-rooted kind should be forked out. Deep digging among choice shrubs by destroying the surface roots is a great mistake. Before pointing over in poor soils a top-dressing of rich compost will be advantageous. Thin and cut back any shrubs, especially common kinds, which unduly encroach on choicer or weaker specimens. A judicious application of the knife for a few years will give to most shrubs and trees the form desired, and the growth so equalised will be retained with very little after-attention. Some discrimination will have to be made between pruning the pyramid and round-headed trees so as to form the most symmetrical shape, as indicated by their respective habits: the great points to be avoided are stiffness, formality, and unnatural shapes. Bare ground among shrubs may be occupied by the spring-flowering plants, such as Winter Aconites, Snowdrops, Primroses, Daffodils, Violets, &c., which are natural to such situations, but to be effective they should be planted in masses. When so grouped such flowers greatly enliven a shrubbery.

Herbaceous Phloxes are now moving. Old plants will have grown considerably aboveground; they should be taken up and divided, replanting them in fresh soil well enriched with manure. Plants not over-large should have the shoots freely thinned out, leaving the strongest only, with a view to the production of fine heads of bloom. Cuttings of choice varieties may now be inserted, and if they are well grown they will produce much finer heads of bloom than old plants. Push forward the pruning of climbers and other plants against walls or trellises in the open, leaving the strongest and best ripened wood only to be trained-in, avoiding overcrowding. Roses of the Tea-scented or Noisette class should have the ripest and strongest wood only retained, laying the growths in their full length, removing only the unripened points of the shoots. To spur a majority of climbing Roses is to secure a fine growth of young shoots but no flowers. No time should be lost in replanting Box edgings, relaying turf, and completing the planting of all deciduous trees and shrubs.

Roses are moving. Any contemplated planting of new beds or borders or filling up vacancies should be completed as soon as possible. Roses prefer soil of a retentive kind, but it must be well drained. In making new beds or borders incorporate some strong manure with the soil. Many herbaceous plants are commencing growing, and should in the case of tender kinds have a light mulch of some protective material, such as partially decayed leaves or bracken in a dry state. The borders should be dressed, and if required re-arranged. Any plants that are too large may be taken up and divided, planting the tallest growers at the back or centre of the border or bed, disposing them so as to appear to the best advantage when flowering. All plants of this kind are benefited by the application of fresh compost and having short manure lightly pointed in about the roots.

FRUIT HOUSES.

Pines.—Proceed with the potting of the suckers or rootless plants, for which a bed should be in readiness as before advised; 5 to 7-inch pots will be sufficiently large. They must be perfectly clean and dry; drain them an inch deep, avoiding small pieces of crocks, and place a little rough compost over the drainage and sprinkle with soot. Ram the compost (turfy loam) firmly around the base of the sucker, and plunge the pots in the bed. Do not apply water until roots are formed, which will be in about ten days in a bottom heat of 90°, when water should be given as required. Maintain a brisk bottom heat, with the top heat 60° to 55° at night, and 65° by day from fire heat. Any plants in small pots in an enfeebled state should be shaken out, disrooted, and treated as advised for the suckers. Healthy plants which have been wintered in small pots may now be shifted into larger; from 8 to 10-inch pots are suitable for Queens, the stronger-growing kinds having pots proportionally larger. The soil should be lumpy, rejecting the "dust," and be pressed very firmly round the old ball of soil. Plunge them in a bottom heat of 90°, having the top heat 60° at night, or a few degrees less in cold weather, 65° by day from fire heat and 70° to 80° from sun heat. The earliest-started plants will be in flower; avoid wetting the fruit whilst in that state, but maintain the moisture by sprinkling, increasing the temperature about 10°.

Strawberries.—Advantage should be taken of every opportunity to increase the temperature by sun heat rather than endeavouring to keep it down by a large influx of cold air, which is very inimical when the flowers are expanding. Plants swelling off their fruit should have weak liquid manure. On no account must the roots become dry, yet a sodden state of the soil is quite as pernicious as drought. The watering should be copious until the

fruit changes colour, after which the supplies may be less frequent; a drier and lower temperature is also necessary to secure high flavour. Our early fruit is had from plants in pots on shelves, and as we have vineries and Peach houses started at intervals from December to March a succession of Strawberries is maintained from early March until the fruit ripens in the open ground. As fire heat is employed in all the houses we now place a quantity of pots at this time in a ground vinery, at which time the last batch is placed in the late Peach house and vineries. It is now a good time to introduce Strawberries to the shelves of the orchard house.

PLANT HOUSES.

Ferns.—Proceed with the potting of these plants at once, especially those required in quantity for furnishing purposes. *Adiantum cuneatum* is still one of the best. Plants which have been kept cool and dry for a time may be divided, those in 6-inch pots being separated into four, larger sizes into correspondingly more pieces, and be potted singly into $\frac{1}{4}$ to 6 or 7-inch pots, according to the size of the pieces and the purposes the plants are intended for. They are placed in a house having a temperature of 60° to 65° by fire heat. Water is given sparingly until growth takes place, and then is applied more liberally. A good moisture is maintained by sprinkling the house frequently. Air is given moderately. Ferns grown for cutting should not be grown in much shade and a close moist atmosphere, as the fronds so grown soon wither when exposed to light and a dry atmosphere. *Adiantum assimile*, *gracillimum*, *formosum*, *concinnum latum*, *trapeziforme*, *tinctum*, and *farleyense* are very useful, all of which may be increased by division. *Davallia Mooreana* is very useful for cutting, as indeed are most of the *Davallias*, also *Pterises*, which are best raised from spores. *Lygodium scandens* is very desirable for twining round stems of stands, &c., on dinner-tables, and is increased by division. *Gleichenias* endure well in a cut state. They also are increased by division, but the less of it the better. Lumpy peat is required for them. Bold, wavy, pendant fronds are represented by *Goniophlebium subauriculatum*, *Nephrolepis davallioides*, and *Woodwardia radicans*, the two former being increased by division and the latter by young plants borne at the point of the fronds. Where much furnishing is done a quantity of hardy Ferns should be grown for the purpose, particularly the varieties of *Athyrium Felix-femina*, *Lastrea dilatata cristata*, *Polystichum angulare* vars., the crested forms of *Scolopendrium vulgare* and *Adiantum pedatum*, all of which may be had in good order early in the season by forwarding them in a warm greenhouse temperature, they too requiring light and ventilation if the fronds are expected to be at all durable. *Selaginellas* also should be grown in quantity, particularly *S. apoda* and *denticulata* for surfacing, *S. cæsia* being fine for brackets; one of the best for cutting is *S. Willdenovi*. Fibrous peat is suitable for a majority of Ferns, but *Adiantum farleyense* and *A. cuneatum* do well in fibrous loam. Drain the pots well, and in the case of plants not grown for special purposes give a moderate shift. Have the shading ready, but use it only during hot sun to prevent scorching. Maintain a moist atmosphere, watering carefully until the roots are established in the fresh compost. Do not remove the disfigured fronds until they lose their vitality, as it has a weakening tendency; especially is this the case with Tree Ferns.

Stove.—*Isoetes gracilis* divide into small pieces, and pot in 8-inch pots; also place about half a dozen cuttings in the same size of pot of *Panicum variegatum*. These, with some of the *Selaginellas*, are useful for fringing stages, &c. *Paulinia thalictrofolia*, take cuttings of the young growths and grow-on in the light. The leaves are finely divided. Sprays of this and *Cissus discolor*, also *Passiflora trifasciata*, are useful in a variety of ways; or the plants may be grown in small pots. *Plumbago capensis* starting into growth, take cuttings off with a heel of ripe wood, and strike in brisk moist heat. Pot-off when rooted, and grow-on. Old plants should be encouraged to grow by a brisk moist heat with plenty of light, and will come in early. Those planted out top-dress. Cuttings or eyes of *Ficus elastica* strike readily in brisk heat, also *F. Parcellii*. *F. repens* should be grown so as to have long sprays. Shift *Gloxinias* into larger pots, and start another batch; also *Caladiums*. The *Achimenes* started early should be transferred to the pots or pans they are to flower in. Do not crowd the plants too much, and stop them when 4 inches high. Start another batch for the principal summer display. Proceed with the potting of such plants as require a shift, which is only to be done in the case of such as have the roots in an active state. The soil for potting stove plants should always be warmed before being used. Most evergreen stove shrubs prefer peat; it should be lumpy and have a free admixture of sand, the drainage being thorough. *Marantas*, *Crotons*, *Dracenas*, and *Pandanus* shift into larger pots. Repot *Alocasias*, which do best in two parts of fibrous peat, two parts of chopped sphagnum, and one part of well-decayed caked manure, with a free admixture of broken crocks and a sprinkling of sand and charcoal. *Alocasia macrorrhiza variegata* does best in two parts of turfy loam with a third of decayed manure and a sprinkling of sand. *Gymnostachyum*s and *Vriesias* do well in lumpy sandy peat well drained, also *Aralias* of the *Veitchii* type. *Ardisia crenulata* is best raised from seed sown in

shallow pans, potting singly in small pots when the plants are large enough to handle. Last year's seedlings shift into larger pots ($\frac{1}{4}$ will be sufficiently large), keeping them near the glass. The temperature may now be raised to 70° to 65° at night, 75° by day, rising to 85° or 90° from sun heat. Sprinkle the paths, &c., two or three times a-day according to the weather, ventilating carefully. *Clerodendrons* and all quick-growing plants will be benefited by the application of weak liquid manure at every alternate watering. *Passifloras*, *Ipomeas*, and other roof climbers should now be cut in, and the borders have a few inches of the surface soil removed and replaced with fresh compost, giving also a good soaking with tepid manure water not too strong.

Pits and Frames.—Admit air freely to plants in frames, removing all decayed leaves, and water more freely as the sun is more powerful. Violets may have the lights removed in bright mild weather, and should have an application of weak liquid manure occasionally. Shift Intermediate Stocks into larger pots, or if planted out lift them with balls and place three plants in 6-inch pots. They do best on a cool bottom. To *Campanula pyramidalis* give larger pots as required, also to *Humea elegans*, these doing best in cold pits with frost only or barely excluded. *Schizostylis coccinea* after flowering should be hardened off preparatory to being divided and planted out, also Christmas Roses. Lilliums will now be moving, and should have the soil kept moist, also *Tritonias*. Pot *Tigridias* and *Gladioli* for planting out after a time for early bloom. Sow plentifully seed of such annuals as *Mignonette*, *Nemophilas*, and *Schizanthuses* for early flowering in pots, not omitting the ornamental Grasses, such as *Agrostis nebulosa*, *A. pulchella*, *Stipa pinnata*, &c. Cockscorn and *Celosia pyramidalis* sow in heat, also *Petunias* double and single, which are fine for pot culture. Pot a few plants of *Campanula calycanthema*, placing them on a cool bottom, and give them weak liquid manure occasionally after the roots are working freely. Other hardy plants will suggest themselves as desirable for forwarding for an early bloom in pots.

TRADE CATALOGUE RECEIVED.

R. Pennell & Son, Lincoln.—*Spring Catalogue of Flower and Vegetable Seeds and Gladioli.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

SALIX BABYLONICA (G. S.).—This is rather a tender tree, and even in the south its young shoots are frequently injured by frost and canker ensues; consequently, unless your position in Scotland is very much sheltered it would not be safe to plant this Willow extensively. The same remarks apply to *Escallonia macrantha*.

ROSES.—Some correspondents would be obliged by Mr. M. D. Sewell stating the stocks on which his Roses are worked and what manure he uses. Bracken can be obtained from the heaths near London. Roots are formed chiefly during the spring and summer.

MELONS (A Young Correspondent).—You can grow them well if you can command a minimum temperature of 60°.

GASLIGHT IN CONSERVATORY (G. R.).—The small escape of gas when lighting it cannot injure the plants.

GAS LIME AS MANURE (A. S. M.).—Twenty bushels per acre will be sufficient to destroy the grubs. The white eggs on your Vines are probably deposited by some weevil, but no one can decide until they produce larvae.

SEEDS, &c., FOR TEXAS (Concha).—Take seeds in small brown paper parcels. Scions stuck in a potato will keep fresh, and you must graft on stocks of the same or closely relative genera. You will find good instructors in Texas.

MUSHROOM (H. W.).—The specimen sent to us does not appear to be the true Mushroom.

ERYNGIUM AMETHYSTINUM.—"G. D." wishes some of our readers would state where seeds of this plant can be obtained.

EUCALYPTUS GLOBULUS.—"E. P." asks where this tree grows unprotected, and where plants of it can be purchased.

CYCLAMENS (G. S.).—Your request shall have our attention.

HARDY PERENNIALS (J. A. C. F.).—Any of the chief florists can supply them though not in their catalogues.

IVY EDGING (Idem).—Small plants should be inserted about 6 inches apart, larger plants at proportionally greater distances, pegging down the growths if they require it.

CHRYSANTHEMUM CULTURE (G. B.).—Our "Florists' Flowers for the Many" contains instructions for growing Chrysanthemums. The practice of successful cultivators is also fully detailed in two numbers of the Journal—Nos. 819 and 820, of December, 1876.

ERRATUM.—At page 143, right-hand column, ten lines from top, for "12 inches apart" read "2 inches apart."—A. K. G.

CRESTED FERN (*G. D.*).—The frond sent of your seedling Fern (*Pteris serrulata cristata* or *lacinata*) is very distinct. We have seen many crested varieties of this Fern, but not one having such finely divided fronds as the specimen before us. If the plant is a good grower and retains its character it will be very acceptable for decorative purposes.

SMALL GREENHOUSE HEATING (*H. H. W.*).—Write to the makers you name, stating the size of house and asking for particulars and prices. The plant you refer to is probably one of the numerous varieties of *Coleus*.

GLOXINIAS (*W.*).—The following are twelve good and moderately priced varieties:—*Erect flowers*—Candeur, pure white and rose; Mr. Baines, purple and scarlet; Esperance, delicate rose, mottled; Pegase, white and scarlet; Prince Leopold, purple and scarlet; Skeltoni, crimson, primrose, and lilac. *Drooping flowers*—Alice, mauve and buff; Crème et Violet, purple and violet; Charles Dickens, purple shaded violet; Goethe, white and rosy vermilion; Ida, creamy white and blue; and Rose d'Amour, white and crimson lake. Your other question is answered in "Our Letter Box."

RAISING YEWs FROM SEED (*A Country Vicar*).—We have gathered bushels of Yew berries and raised thousands of seedlings, we have also gathered berries of the Irish Yew and sown them, but only a comparatively small number have germinated, and scarcely any of the seedlings have been true to character, probably because the flowers have been fertilised by pollen from the common Yew. Although some of the berries to which you allude may have been swallowed by birds, that process is certainly not essential to the germination of the seeds. We do not think there is any foundation for the assumption respecting the other seeds you name.

VIOLETS (*C. C. J.*).—We cannot inform you of the address. Correspondents do not covet such applications. The varieties required could be obtained for you by any of the florists who advertise in our columns.

FAILURE OF ROSE MADAME CHARLES WOOD (*A Leek Rose-grower*).—We can only attribute the failure of your plants of this Rose to the presence of some noxious substance in the soil. It answers very well with us planted among numerous other sorts. All the "Rose" nurserymen offer it for sale at a low rate, which would not be the case if it was generally a bad grower; and Messrs. Wood, who have raised and sold large quantities of it, inform us that they have never had a complaint of it, nor do they regard it as a delicate Rose. We shall be glad, however, to hear what other rosarians say respecting the growth of this Rose.

HEATING PROPAGATING BED IN A GREENHOUSE (*P. L.*).—A charcoal stove placed under the bottom of the bed would probably answer tolerably well provided you can shut it off from the remainder of the house. Convey the fumes through a pipe outside the house, and keep the stove supplied with fuel. A flow and return pipe taken under the bed from your kitchen boiler would answer much better and prove both a saving of labour and fuel.

CULTIVATION OF ROSES FROM CUTTINGS (*A. J.*).—Your Roses in pots which are growing freely from cuttings made last August require no pruning now. When the roots reach the sides of the pots repot in rich loam, first placing a handful of rough rich manure over the drainage, pressing down the soil firmly and keeping the surface quite an inch below the rim of the pot, so as to ensure thorough watering. Give bountiful supplies of clear liquid manure. Keep the foliage clean, and secure an equal distribution of vigour and symmetrical plants by nipping off the tips of leading shoots or any others likely to become too rampant. If you intend the plants for open beds harden and plant out early in April, taking especial care to have plenty of manure in the soil and also to give sewage. Regulate the growth as required, and strong handsome plants may be obtained in a single season.

WATERING A VINE BORDER (*J. L.*).—Clear water will answer perfectly well for young Vines just planted in fertile loam. It is only as a curative for poverty of soil that we ever advocate the use of sewage or liquid manure of any kind before the Vines are in fruit, then pour on as much of it as you like till the fruit colours, provided the border is well drained.

GRAFTING STANDARD ROSES (*Tyro*).—The best time for grafting the Roses is March, but the scions should be selected now and be placed in soil in a cool moist border to keep them fresh, yet more backward than the stocks. The prunings of Roses may be used as scions provided they have two to three buds that turn outwards. Both ends of the scions should be cut, and those shoots that are moderately thick are the best, but the wood should be young. One scion should be placed on each side of the slit made in the stock if it is thick enough to admit of it.—H. W.

RABBITS DESTROYING CROPS (*A Regular Subscriber*).—You have no legal remedy. A dog chained in the garden would prevent the rabbits trespassing.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE CULTIVATION OF BARLEY.—(Continued.)

In reference to the application of manure for barley, it is not often required upon well-tilled farms, especially when sown after turnips fed off. It is, however, different when sown after wheat; the barley will then require a moderate dressing, say 2 cwt. of Peruvian guano, or 1½ cwt. of nitrate of soda and half cwt. of mineral superphosphate per acre. We have known either of these applications answer well, the cost being nearly equal, and they may be sown broadcast just behind the drill and harrowed-in. Other circumstances may occur to render manuring desirable, and the dressing recommended will be found the best and most economical in any case. The mode of laying the land and the size of the ridges at the final ploughing before seed-time is a matter of consequence; for although barley is a summer grain, and the size of the ridges is not of so much consequence for that

crop, yet, as it is usual for the clover to be seeded with it, it is requisite that the land should be laid in such a manner and the ridges of such a form that the clover plant may be uninjured by stagnant water during the winter months, and also that the ridges should be made of the size required for the succeeding wheat crop, because when it is intended to sow wheat at one ploughing after clover the size of the ridges cannot be easily changed.

Let us now refer to the advantages and risks of early sowing. The time of sowing barley is usually regulated by several causes, but chiefly by the nature of the soil and influence of the weather. Upon what is termed good barley soils the best time for sowing is as soon after the middle of February as the land can be made to work freely and the seed can be deposited in a fine and dry bed. It is sometimes sown as early as the middle of the month of January, when the weather has been fine and seemed to invite the seedsman; but there can be no advantage in sowing thus early, the risk being great, not so much of destroying the crop as of injury from a series of checks upon the growth of the plant by frost. As it is usual to sow clover or grass seeds in the barley crop, and the time best suited for this operation being the period of sowing the barley, there would be great risk of the young clover plant being destroyed by frost if sown so very early. The period for sowing may be said to extend from the middle of February to the middle of April, but after that time our experience teaches us that in the majority of seasons a good malting sample will not be obtained. It is seldom that an early season can be obtained upon strong soils, for although the land may be forced into an early tilth in some years, yet the nature of the soil opposes the favourable progress of the plant if sown previous to the middle of March. The bulk of the crop will be found to differ from a variety of causes, such as the preparation of the land, the effect of climate, the sort of seed, and the attack of wireworm and other enemies to which the plant is liable.

We will now refer to the varieties of seed best suited to the soil and climate of different districts, which can only be ascertained by the practice and experience of the cultivators themselves, who are ready to admit that however successful any variety may prove in its produce as adapted to a particular soil or situation, that a continual deterioration goes on unless a change of seed from varying soils takes place. The propagation of different varieties of barley are constantly going on, some maintained for a time and then disappear. Amongst the many sorts now in cultivation must be noticed Chevalier, American, Nottingham, Golden Melon, and Moldavian, with some others. The Chevalier certainly stands highest in estimation for malting purposes, and probably also as giving the best return for cultivation, and particularly that called Hallett's Pedigree, which is known to have been selected and propagated from the Chevalier sort originally, and it is now the best variety for all dry and kind soils which prevail in the eastern and south-eastern counties, for under Mr. Hallett's judicious selection from the best, longest, and strongest ears and stalks, and the kindest and plumpest grains, it has now attained a value which it never could have done by the old plan of simple selection of sort only, for until the Pedigree stock became available the ordinary Chevalier had receded in cultivation, more particularly on loamy soils. In those districts where it has not succeeded the sorts in favour are the Nottingham, American, and Moldavian (often called Thanet). The latter is a short small grain, and will bear later sowing than any other sort with which we are acquainted. The two former varieties are better suited to the stronger soils and moister climate of the western, northern, and some of the midland counties, especially the American sort, for it produces long strong straw and good ears, but the grain is generally coarse, and although it gives under good cultivation a large yield, yet the grain is not so much esteemed for malting as Chevalier and Golden Melon, which is probably the same variety, only the latter name is given it by some recent propagator.

The quantity of seed required will range from two to three bushels per acre according to circumstances, such as early or late sowing, or whether sown broadcast or drilled. It is, however, some-

times dibbled. When sown broadcast upon poor soil not highly manured at an early period, three bushels of seed may be necessary; when drilled upon land in general in good condition two bushels will be found sufficient, when dibbled eight pecks is considered enough. The object in view in dibbling barley is not only a saving of seed, but giving the opportunity of more effectually eradicating weeds, such as charlock, &c., by hoeing. We do not, however, consider that barley will answer so well in thin seeding as most other kinds of grain, by reason of a thin plant tillering so much as to cause the grain to ripen unevenly, rendering the sample coarse and flinty and unfit for malting, and also diminishing the crop.

Barley is unlike wheat—it is not subject to smut; yet some farmers make a practice of steeping their seed for the purpose of preventing the black ears, but we do not consider it is an ascertained fact that they are propagated by contagion like the smut balls in wheat, being rather to be attributed to a combination of causes, such as the weather, the state of the land, the time of sowing, and the lack of change of seed. Barley is also subject to mildew or blight, commonly called "red rust," which usually attacks the plant about one period, just before coming into ear. When the crop is very gross sudden changes of temperature in the weather will often produce it, more particularly when grown on land with a northern or north-eastern aspect. One of the greatest requirements is how to produce the best malting sample, for it is well known that much the largest portion of the general growth is beneath the malting quality. But there is one idea which strikes us as worth following out, for it is an admitted fact that barley when grown in admixture with oats (commonly called *drege*), and sown early, is sure to be a good sample, and this fact seems to point to thin seeding, or, what is preferable, wide drilling; and we know cultivators who drill barley at 12 inches between the rows with about two bushels of seed per acre upon both strong and light land, and the substance of the sample has proved much greater than when sown broadcast or closer drilling has been adopted. There also seems to be no reason why the practice of sowing oats and barley in admixture in the proportion of two-thirds oats and one-third barley should not be extended, for the sample of barley is next to a certainty to be of the best malting quality. It may be adopted with great advantage upon strong or loamy soils, as we have frequently grown from ten to twelve quarters per acre when mixed seed was sown. The next question arises, How can the crop be separated so as to take out the barley from the oats clean enough to offer as a sample for malting? and we recommend that it be done as follows:—Pass the mixed corn through the barley *aveller* or *hummeller*, which denudes it of all the beards, leaving only the clean grain, and then by the use of Coleman & Morton's patent adjustable rotatory corn screen, the barley will be separated from the oats so perfectly as to realise the top price for malting purposes. This screen should also be employed when the samples of barley are uneven, for at a small cost instead of selling a sample as grinding or distilling grain, the best barley can be separated and sold for malting, and the thin grain sold or used for inferior purposes, and it will be noted as not being expensive when the screen will effectually separate the grain at the rate of from fifty to sixty bushels per hour.

The time and mode of cutting and harvesting differs from some kinds of grain in being depreciated by early cutting. It should always be allowed to stand until dead ripe if the grain is required for malting purposes, the corn will then become mellow and kind. A common rule as regards ripeness is indicated by a wrinkled and shrivelled appearance of the skin of the grain, when the ear droops pointing to the earth. The mode of cutting barley is generally by the mowing machine if it is intended to be carted as loose corn, and if the weather proves fine it is the better for laying a few days, as the dews at night time improve the malting quality. When, however, the crop is tied into sheaves and set-up in stooks it will not all suffer from wet weather, but when it lies on the swarth the whole of the grain is often discoloured. The thrashing and dressing of the crop is of consequence, and until the past few years barley was thrashed with the flail in some districts, and no doubt fewer broken corns occur in the sample than when thrashed by steam machinery, but the cheapness and expedition of the work done by the machine is so much greater that the old flail is now almost entirely thrown away and has fallen into disrepute.

WORK ON THE HOME FARM.

Horse Labour.—If any chalking is left undone it should now be attended to, and if no frost comes to shake the lumps, they should be broken fine into pieces about the size of a turkey's egg; the act of ploughing will then bury the chalk lumps, which it always ought to do, because any pieces left on the surface after cultivation will often become almost as hard as stones in consequence of exposure to wind and rain and summer sunshine. The horses will also be employed in ploughing and working the land for fodder crops, such as summer vetches with oats mixed, $1\frac{1}{2}$ bushel of vetches and 1 bushel of Black Tartarian oats per acre. When, however, the vetches are required for feeding dairy cows the seeding should be $1\frac{1}{2}$ bushel of vetches and 1 lb. of tall rape per acre. The rape holds up the vetches well

and proves one of the best fodder crops which can be given to dairy cows for the production of butter or milk to be sent to London or elsewhere. It is now a good time to sow *Trifolium* of the early crimson-blossomed variety, for although it is usual to sow this crop in the autumn, it is more certain to succeed when sown in spring, having then few or no enemies—such as slugs, &c. The land, however, will require to have been ploughed beforehand and settled-down close, then harrowed and rolled until perfectly fine. Then, at last, use the ring roller, sow the seed 20 lbs. per acre, and harrow-in with chain harrow. At eleven or twelve weeks end this crop will be a full one, especially if the land is in good heart and condition; if not, 2 cwt. per acre of nitrate of soda should be sown and harrowed-in at the time of seeding the *Trifolium*. As fast as this crop is cleared it may be sown for turnips, or with vetches and oats, or tall rape as above stated. We saw last October a splendid lot of fodder of this kind sown the first week of July. There is now plenty of work for the odd horse, and the employment will consist of carting couch or weeds to a heap, or on to pastures, carting hay, chaff, &c., to sheep in the field, roots to the cattle in the boxes and yards, and for breeding sows. Much odd work will have to be done if it is intended to keep-up a decent and cleanly appearance of the homestead.

Manual Labour.—This will consist of filling, and laying-out and spreading chalk, the women assisting in breaking the largest lumps. This will now be the best time of the year for doing any draining on the arable land, at least for setting-out the work, for any land that is in fallow if it requires draining the first drying winds in March will be sure to show the wet spots, and bird's-eye springs if any, for after the winter's rain the fine weather succeeding, the driest land will look white and dry, whereas the wet spots or parts will remain of a darker colour for a considerable period, and this enables the farmer or bailiff to set out the work with an exactness not so easily accomplished at other times of the year. The men may now proceed to cut the drains in order that the following work afterwards may be completed in time for the root or other crops to succeed the work of draining. The tiles for the work having been brought to the farm during the winter, the odd horse may now draw them to the field where they are wanted. The men who are in attendance upon the dairy cows, the fattening and store stock in the sheds and yards, will now be fully employed. The store pigs and breeding sows will require constant attention; the latter as soon as the young pigs are weaned should be turned into and fed with roots, &c., in a yard with hovel attached for shelter at night and in rough weather. The yard of any required extent should be fenced close with strong iron cattle hurdles, and may be littered with long dung direct from the stables, and in this way the accumulating dung will be well preserved, the pigs constantly treading it down and adding to its value by their own droppings and consolidating the mass, which would under other circumstances deteriorate by heating, &c. When the sows are about to farrow they should be moved to a comfortable pen for that purpose (and which will be described at a future time); here they remain until the young pigs are weaned, when they return to the open yard again, and we have always deemed this to be especially desirable, as they are found not to breed well and bring but few pigs at a farrow when kept in close pens without exercise, a certain amount of which we have found to be essential to the well-doing of all breeding animals.

THE PEACOCK.

It has always seemed strange to us that this magnificent and aristocratic bird should be so seldom seen. So glorious are its hues and so elegant its motions, that even people who may be utterly uninterested in ordinary poultry cannot fail to be fascinated with it. Not only when strutting on a terrace or spreading his tail is a Peacock a bird of beauty, but his flight too is light and graceful. We have often watched a large company of them at a farm near Oxford, glancing in the sun as they flew from stack to stack with the greatest ease. It is true that they are bad gardeners, but not worse than other kinds of poultry of less beauty which are tolerated; and doubtless many of our readers would sacrifice a few leaves and buds for the sake of such pets, or possess premises sufficiently spacious to afford ample room for the perambulations of a few Peacocks without allowing them in the region of the dressed garden. For those who are so fortunate we will give a few notes upon them.

The Peacock is a long-lived and hardy bird. The chicks may easily be reared under a Turkey hen among her own progeny, and will develop powers of flight with marvellous rapidity. They detest all restraint, and soon learn to perch on high buildings, and there defy winds and frost; still they may easily be tamed to extreme familiarity, and are not only companionable in life but if killed young are a lordly and delicious dish on the table. Of course they have their faults. Some old cocks become cruel; but, as with Turkeys, the produce of a cock known to be amiable should be sought for. Again, their voices are not generally thought melodious, though we never could dislike them, but always thought there was something charmingly and mysteriously weird in their

cry, and quite agree with Mr. Dixon, who says that only nervous and fastidious persons object to it.

For lovers of the rare and curious we will mention a few of the Peacock's varieties. The Common Peafowl (*Pavo cristatus*) is too well known to need any description.

The Pavo spicifer or Peacock of Java is by far the handsomest species we have seen. We suspect that this is the same bird as that vulgarly called the Japan Peafowl. There is a beautiful pair of them in the Regent's Park Gardens, which we saw last week in glorious plumage, in spite of their miserably narrow quarters. The neck of the cock is an indescribable mixture of sheeny gold and green, his head and face curiously parti-coloured with well-defined patches of rich yellow, blue, and violet, his back of glossy copper, each feather laced with black. The hen's general colour, unlike the sober tints of her common cousin, is the same golden green as that of the cock's neck; her head has likewise the same bright yellow patches, and both her flights and those of the cock are copper-coloured.

The Pavo nigripennis or Black-winged Peafowl is a native of Sumatra. The common Peafowl is least gaudy in its wings, which are of brownish grey hues not unlike those of the hen Pheasant; but this bird excels in this very point, his wings being of a glossy black shaded with Prussian blue.

Then comes the White Peafowl. In this bird certainly some of the Peacock's peculiar glory is lost; still its white is a singularly pure white, and the eyes of the tail are like glistening gold. By far the best specimens of the variety we have ever seen were those of the Vatican. It may not be uninteresting to relate that the Pontiff who has just gone to his rest was very fond of his poultry and Pigeons. We had the privilege once of spending an afternoon in his gardens, to our mind the most perfect in Europe for their varied charms, and of being shown all the birds. At the end of the great terrace, which runs at right angles to the galleries and looks down upon the sunken gardens, is a grille gate; hither the Pope often walked in former days, and latterly was carried in his chair. On each side were high-domed aviaries full of Ring-doves, Jacobins, and Fantails. Through the gate was the great poultry yard, a truly royal one, and a perfect paradise for its inmates, planted entirely with grand and luxuriant orange and lemon trees, among which a perfect troop of white Peacocks, Guinea Fowls, and other poultry desported themselves. A fountain played in a central pond, wherein white Chinese Geese and other fancy waterfowl revelled.

Lastly, the Pied Peafowl is, of course, a crossbred bird between the latter variety and one of the coloured birds. In our opinion it loses the beauties of both parents. If these stray notes should tempt anyone to go more deeply into the fancy of this gorgeous habitant of the east, and to study its sub-varieties, we shall be truly glad.—C.

VARIETIES.

WE have received a copy of Messrs. J. K. & R. R. Fowler's *Descriptive Catalogue of Prize Poultry and other Pedigree Stock*, which embraces all the best breeds of poultry, ducks, geese, turkeys, pigs, and cattle. When we state that the owners of the Prebendal Farm, Aylesbury, have since 1871 carried off as prizes 104 silver cups, 358 first prizes, 276 second prizes, 179 third prizes, and over 600 high commendations, we need not say more as to the quality of the stock these gentlemen supply.

THE agricultural schools for improvement which were established on trial in Nassau, Germany, some ten years ago appear to have been a great success. In the winter of 1869 only nine schools were in existence, in 1870 the number had increased to ten, in 1871 to forty-two, in 1874 to ninety-one, and in 1876-7 to ninety-two. Last winter these schools were attended by 1457 pupils, of whom 1830 were between fourteen and twenty years of age, 94 between twenty and thirty, and 33 more than thirty years old. The teachers are paid according to results, which are tested by periodical examinations made by appointed inspectors.

AN American writer concludes an article on strikes and restricting the hours of labour as follows:—The loss of so many hours of daily labour is just so much loss of real property in the world, and so long as the workman lives he is just as much a loser as is the capitalist who employs him. Unreasonably high wages are as reactionable as any other extreme. Could organised strikers compel capital to pay more than their labour was worth, the workman would not be long in finding out, by the increase of his butcher's and grocer's bills, that he had only had his labour for his pains. All associate interests to be lasting must be upon an equitable basis. The bargain that is one-sided and unreasonable can never be made permanent. The laws of compensation are inevitable. Justice will assert itself at last. There is a third silent partner to every bargain that was ever consummated.

WITH forty-seven millions of arable acres at command, the population of Great Britain and Ireland is largely dependant upon foreign supplies for daily food. The extent of this dependence is not generally understood; but last year Great Britain expended for foreign food no less than £96,879,000. The year

before the money paid for similar articles amounted to £87,129,000. So in one year there is an increase of hard cash paid away to foreign lands of nearly ten millions, or there was within a few hundred thousands of an increased outlay of ten per cent. These startling facts are surely enough to make everyone pause to consider what we are doing at home to allow this outlay to be possible. Freetraders have said over and over again that such an expenditure is the best thing that could occur, as the money is scattered abroad in new countries, and new markets are created. But it seems to us that if a large share of this ninety-seven millions sterling had been earned by the agricultural labourers and tenant farmers of Great Britain for subsequent distribution by them equal markets would have been created at home, and the manufactured articles thus in increased demand at home might have been supplied at a less cost for carriage.—(*Irish Farmer's Gazette*.)

A CORRESPONDENT of the *New York Tribune* gives the following results of experience in ploughing:—1, Plough only when the ground is dry enough to leave it mellow. 2, Plough so as to leave the upper or richer element as Nature does, at the top. How can deep furrows be made without leaving the upper surfaces at the bottom? Use the subsoil plough, and you are all right; when the soil is deep, deep ploughing will do, and it will do with heavy surface-manuring. The nearer the surface the fertilisers are, the better the crops will be. I have had good crops of corn with late fall ploughing, and in spring spreading and harrowing in the manure. Many farmers think the manure lost by evaporation unless it is pretty well buried, but if too deep nothing but a miracle will raise it.

CLOTH FROM FEATHERS.—A new industry is said to be extending rapidly in Paris: it consists in the manufacture of a cloth five times lighter and three times warmer than wool, from the feathers of domestic and other birds. The material is waterproof and takes dye readily.—(*Journal of Applied Science*.)

IN the London hay markets prices for good meadow hay were dearer on Saturday last, while straw was rather lower. Prime clover 100s. to 134s., inferior 85s. to 95s.; prime meadow hay 85s. to 96s., inferior 70s. to 80s.; and straw 44s. to 53s. per load.

AMONG other disadvantages, says the *Agricultural Gazette*, which a warm winter brings with it is the too rapid growth of turnip greens. Swedes that have been left unpitted have made alarming progress during the last fortnight, and there seems to be a good chance of their deteriorating sadly in quality, unless steps are taken to check their advance. Such a season as the present teaches that swedes, which must be fed off late, ought to be pitted if it is desired to realise their full value. If it is inconvenient to pit swedes, running may be checked by giving each root a shake in the ground, and the same effect might, we think, be produced by removing the mould-board from a plough and running the share in a line just below the roots.

THE history of Peruvian guano, says an American contemporary, is an interesting one. None was brought from the granitic rocks of the Chincha Islands to Europe for trial till 1840, when twenty casks were imported into Liverpool. The next year the shipments amounted to several cargoes. The exclusive right of digging and shipping guano for the term of nine years was sold at this time by the Peruvian and Bolivian Governments for the sum of 40,000 dols., but the contract was soon after repudiated by the former, as the increasing demand for the article developed the immense value of the deposits, which lie to the depth of 50 or 60 feet. The accumulation of the three hundred years preceding 1804 having formed only a few lines of this thickness, the monopoly was soon revived, however, the Peruvian Government confining the exportation and sale to a single house in London and another in New York. Upon the Chincha Islands it was estimated that there were 57,000,000 tons of guano.

WINTERING BEES.

AN experience of many years has satisfied me that no degree of cold ever encountered in this country is prejudicial to bees during the winter provided their hives are dry in the interior. In the winter of 1860-61 my bees were exposed to thorough ventilation. One colony was in a box of inch deal 11½ inches square inside by 9 inches deep. It was exposed to the full rigour of the season, with an aperture 4 inches square open in the crown board, and with the entrance of the full width, so that the external air circulated freely through the hive. The box itself was painted, but had no kind of external cover or protection. The rain and snow were kept out by a simple sloping loose cover fitting loosely on the top of the hive, which was situated in the open garden.

At the end of January I found that breeding was going on in spite of this free ventilation. I pursued this system of thorough ventilation until the winter of 1875, and never lost a single stock except by lack of food. Wooden hives properly ventilated seem to me quite equal to those made of straw. In 1863 I obtained a frame hive from Mr. Woodbury made of yellow pine. This hive has been almost constantly tenanted winter and summer up to the present time, and is now practically as good as ever.

Some time afterwards Messrs. Neighbour & Son began making square straw frame hives, and I obtained several of them, hoping to find them superior to wooden boxes as winter domiciles for bees. Year after year I worked them side by side, but could not perceive that the straw had the slightest advantage over the wood. During winter both were equally dry if ventilated, and during the spring, after the ventilation had been stopped, the condensation was quite as great in the corners of the straw hives as of the wooden one. All my bees are now domiciled in wooden hives, though I have several good straw frame hives in my loft.

At present I am trying the system advocated by Mr. Abbott. The slides of my Stewartons are withdrawn, and the crown boards of frame hives removed in November, and the hives are covered with two or three thicknesses of carpet during winter and spring. Boxes thus treated are, I find, perfectly dry during the winter, and almost equally so in the spring; but when the population is rapidly increasing in March and April with warm days and cold nights, a little condensation takes place in the corners of square hives, which is nearly or entirely avoided in octagon boxes. When the quilt is used as a winter cover it is essential that the exterior of the hive should be thoroughly ventilated, so that the vapour rising through the carpet can be carried off at once. If the hive is covered with a close-fitting top, or if any impervious substance is laid on the top of the quilt, condensation takes place and the carpet becomes mouldy and saturated with moisture.—J. E. BRISCOE, *Albrighton, Wolverhampton.*

THE INTRODUCTION OF THE LIGURIAN OR ITALIAN BEE INTO ENGLAND AND GERMANY.

(Continued from page 160.)

"In September of the year 1853," continues Dr. Dzierzon, "the fourth meeting of the German bee-keepers was to be held in Vienna. While preparations for this meeting were going on I was asked to send there some empty Mobil hives (hives with moveable combs), as well as some colonies occupying hives of this kind which at that time were but little known; and when I was required to state the price, I requested that a stock of Italian bees might be sent me in exchange, adding that in my humble opinion it would not be impossible to overcome the difficulties of transportation from Mira near Venice to Silesia, *via* Trieste and Vienna. Some time after this I received a letter from Vienna advising me that the desired colony had arrived there and had been delivered to the railway company to be forwarded to me. This joyful message, however, was succeeded by days of anxious waiting—a snowstorm had stopped the traffic on the railroad. I sent to the station at Brieg every day, and I made inquiries by telegraph, but was unable to learn anything of the whereabouts of the stock. At last when I had got tired of sending to the station the stock was delivered at my house. In the evening of the 12th February, 1853, it stood in my sitting-room, and to my agreeable surprise it was safe and sound.

"The ständer hive in which they arrived, and which was about 3 feet high and made of boards scarcely an inch thick, was placed upside down, and the ends of the combs which were somewhat inclined over each other were found to be united by the bees to one another so firmly that it was not easy for the combs to have got damaged. The first sight of the bees was a great surprise to me. I had not expected to find such a difference and such beauty of colour. I also very soon noticed their gentle disposition combined with extraordinary activity. About the beginning of March, when the ground was still partially covered with snow, and my other stocks gave no signs of activity, yet the Italian bees were busy in the hazel bushes, and they got on exceedingly well notwithstanding their having been thrown back a little by being removed into a Mobil hive—a spacious Lager stock. As soon as I noticed drone brood in the hive I caused the bees to rear young Italian queens, and thus obtained twenty-seven pure Italian colonies. I might have obtained a far greater number even in the first year, but to my not exactly agreeable surprise all the drones were suddenly driven out of the parent hive about midsummer, this being probably the time when the drones are killed in Italy. I now left the stock undisturbed, and it completely filled its spacious hive with comb and became so heavy that it required the greatest exertion to lift it. In the following year when I had a larger number of parent hives at my disposal the increase was of course much more rapid, and I was enabled to send a good many small colonies as well as fertile queens only to every part of the country. I have no doubt that at the present time the Italian bee is known and cultivated in most parts of Germany where bee-keeping is practised.

"The introduction of the Italian bees into Germany may justly be regarded as an event of great importance. It has awakened and increased the interest taken in bee-keeping, and prepared the way for a great advance in the theory as well as in the practice of bee-culture. Without the Italian bees bee-keeping would not possess half its charm—to me, at least, it would not. To watch the beautiful Italian bees, especially the first generation of a young queen, playing in bright sunshine is a most interesting

sight to me of which I never get tired. But what interests us most is that the Italian bee, compared with our common grey bee, allows us to make many observations, such as on the duration of life of bees, the origin of drones, &c., and it has been the means of clearing up almost all the formerly disputed points respecting the propagation of bees. If the great authority on bees, Baron von Ehrenfels, had been acquainted with the Italian bees and had made experiments with them, he could not possibly have expressed the opinion that worker bees, if not accidentally dying a violent death, might attain the age of a queen bee, and consequently live four years or longer. At present it is known to everyone who has had an opportunity of introducing Italian queens into stocks of common bees at different times of the year, that worker bees may live six months and longer during the time of rest in autumn and winter, but in the busy time of spring and summer their strength gives way so quickly and their wings become so worn out that they do not live beyond two months. Twenty-five years ago people had not yet settled the question as to the origin of the drones. From the fact that worker bees in hives where they have no queen in the course of time begin to lay eggs, which, however, produce drones only, many bee-keepers supposed this also to take place in hives where the queen is alive and well, it being inconceivable to them that one and the same queen should be capable of adapting the sex of the eggs to the cells. Even Baron von Berlepsch was for a long time of this opinion. But after I had sent him two Italian queens in the autumn of 1853, if I am not mistaken in the time, and when he saw Italian drones appear in the hives to which those queens had been introduced as early as March in the following year, he became convinced that the theory which I advocated was the right one, the queen being the mother of all the bees in the hive, male as well as female. My theory about the drones, according to which they proceed from unfertilised eggs which leave the maternal ovaries capable of developing into male bees or drones, has also been confirmed by the yellow Italian bees, in so far as the drones always belong to the race of a pure mother, no matter whether she has been impregnated by a yellow or black drone, a mixing of the races being noticeable among the female offspring only, because the latter can only be produced from fertilised eggs. By means of the Italian bees it was also strikingly illustrated by Von Balenstein that the old queen if still alive, which was doubted by many bee-keepers, leaves the hive with the first swarm, for after a first swarm and a second and third swarm had issued from his Italian stock the pure Italian offspring were propagated in the first swarm only, whereas a mixed offspring appeared in the parent hive and in the second and third swarms, because the young queens had been impregnated by drones of common bees, which existed in greater abundance than the Italian drones.

"The progress in the theory of bee-culture which had been so much advanced by the Italian bees could not, of course, remain without influence on practical bee-keeping, the former surely being the foundation of the latter. A more correct theory could not therefore but be followed by a more judicious practice. But directly even the introduction of the Italian bees has had a favourable influence on the practice of bee-keeping, because these bees are not only prettier in outward appearance, but they possess qualities which make them a valuable acquisition for practical purposes. It was said at the last annual meeting at Linz that the irascibility of the common bees, which often actually degenerates into a rage to sting, would be sufficient to disgust people with bee-keeping, and it was also asserted and proved that the Italian bees are less inclined to sting, which certainly is a decided advantage; although, on the other hand, it has been mentioned that the Italian bees sting very sharply. This statement may be correct as regards some variety received from other parts of the country (Italy), or having more German than Italian blood in its veins, but it is not applicable to the bees which I received from the neighbourhood of Venice. As the uniformly-coloured grey bee has peculiarities of its own as regards inclination to swarm, differing in the heath districts from other parts of Germany, it is possible that the yellow bee from different parts of Upper Italy and from Italian Switzerland may also possess peculiarities as regards inclination to sting.

"The greater bravery of the Italian bees in defending their stock against thieves and robbers is undisputed, and their indefatigable industry in gathering honey is universally known. What Virgil says of the superior gold-coloured bees as to their gathering plenty of honey for their owner remains true at the present day, after a lapse of nearly two thousand years.

"The Italian bees have been reproached with changing their queens more frequently than the black bees do, and during the first year after their introduction I think I myself made similar observations, which I ascribe to premature breeding. But since the Italian bees have become acclimatised, in consequence of which my bees at present do not expel the drones earlier than other bees do, I do not find the least difference between them and black bees as regards the commencement of breeding and the change of queens. During last spring and summer I did not lose even a single queen.

"A certain able bee-master considers it a great advantage

that the queen bee of an Italian colony is so easily distinguished from workers by her golden colour, no difficulty being experienced in finding her. In practice this is indeed of no small value, as it is frequently necessary to remove the queen, or at least to become convinced of her being alive. How much time do we not often waste in looking for the queen, and yet how frequently do we overlook a small queen, scarcely to be distinguished from a common bee, and uselessly sacrifice the most valuable queens, not noticing our mistake until, perhaps, it is too late to save the colony. But a pure Italian queen is discovered at a glance, even by persons with weak eyes. Searching for the queens of Italian stocks is moreover much facilitated by their remaining quite tranquil during operations, often even continuing to deposit eggs in the cells of a comb which has been removed from the hive, whilst the black bees, which shun the light if operations are not performed very cautiously, generally run away into the most distant corner of the hive and thus necessitate the removal of all the combs. In an Italian colony, especially if the bees are no longer quite pure, a change of queens may generally be noticed immediately by the colour of the young bees, and thus we may convince ourselves of the presence of a strong young queen in the hive without any examination at all.

"It is a well-known fact that the introduction of the Italian bees has been followed by the introduction of other varieties, such as the Carniolan, Egyptian, Grecian, Asiatic, and recently the Cyprian bees. The Carniolan bees are perhaps as good-tempered as the Italian bees, but in the production of honey, which after all is the main point, they are greatly inferior to the Italians. The Egyptian bee is only of scientific interest; in practice it is of no value whatever in our country, because as Vogel and Hilbert have shown, it breeds continually, even in winter, and therefore it winters badly. On the Cyprian bee I am unable to give an opinion, not having made any experiments with it. The opinions as to its value are still at variance, directly opposite views being held as to its irascibility. Should the Cyprian queen bees throughout be of rather a dark colour, like the one mentioned at the meeting in Linz, which had been born with shorter wings and yet became fertile, and on which a good deal of discussion took place. This certainly would be a slight disadvantage in them, otherwise they are splendid bees and have lately been very much praised. I stick to my gold-coloured Italian bees which I received twenty-five years ago, because from the results of my long experience I consider them, with Virgil, the kind of bees which yields the largest harvests of honey.—(Signed), Dr. DZIERZON, Carlsmarkt, 1st December, 1877."

BEE STING.

I HAVE found out a very simple remedy for the sting of a bee. It is an ointment made of soap and honey, spread on a piece of lint or linen, and laid on the part stung. I assure you the effect is marvellous. I suffered such intense agony after having used ammonia, and my hand and arm from the tips of my fingers up to my shoulder swelled to such an alarming size, that I determined never to use that remedy again, and, besides, the irritation was intense. The other day I was stung on the cheek and tried the soap and honey. The cheek and eye became swollen, but not much, and there has not been the slightest irritation.—F. RAMMELL.

SPRING WORK IN THE APIARY.

OWING to last year being unfavourable for bees it is probable that many hives are in a weakly state at the present time. Weak hives are those that have but few bees, for though strong hives may have eaten most of their winter supply of honey we do not call them weak or consider them in a weakly condition. The bees of strong hives may approach the point of starvation and be saved from feeling their need and danger by the administration of food in sufficient quantity. When strong hives die it is generally owing to either the ignorance or inattention of their owners. With weakly hives the case is different; sometimes they will "go off" under the greatest care and skilful treatment. The best doctor is often baffled with cases of patients whose constitutions are bad. I had a letter from Scotland two or three days ago in which the writer says many hives there have already died. The accounts I receive from English apiarists are rather unfavourable; death is reducing the number of their stocks. Owing to the very unfavourable weather last year, especially in the autumn, bees did not breed well, and, moreover, ceased breeding at an unusually early date, hence the scarcity of bees in many hives now.

The question of what is the best way of managing weak hives is a natural one, and forces itself on the attention of bee-keepers after unfavourable seasons. There are two ways of treating weak hives in early spring. One is to unite two of them, making one good hive. If the hives to be united stand side by side the union may be easily and safely effected. Our mode of proceeding has been stated in this Journal. As two or three good hives do more work than half a dozen weakly hives, and scarcely require any

attention, we strongly recommend winter or early spring unions. These should be effected before queens commence laying. The other mode of treating weak hives is good and gentle nursing, and this means keeping the hives well and warmly covered and feeding the bees with good syrup in small doses. The bees of weak hives cannot cover or hatch much in March and April, and can do but little work outside. Poverty of strength and means places people as well as bees at a great disadvantage; poverty is always heavily taxed. Probably one-third of the hives of England and Scotland will be lost by death during the next two months. We advise bee-keepers generally to examine their stocks carefully; hives with only two seams of bees, and some with three small seams, should be marked for union with other weak hives. If unions are not resorted to, then let the bees of weak hives be carefully nursed with a view to obtain an early hatch or two of brood, and thus save them from extinction.—A. PETTIGREW.

OUR LETTER BOX.

FOWLS TRESPASSING (Amateur, N. B. R.).—You cannot legally either shoot or poison them. Give your neighbour notice in writing that unless he keeps his poultry at home you will sue him for the damage they do. If he afterwards does not keep them from trespassing sue him in the County Court.

CLOSING FIELD FOR HAY (W.).—Your gardener is right, and especially if you graze the land with sheep and horses, which bite very close to the ground.

AMATEUR SMOKING HOUSE FOR BACON, &c.—"R. R." would be much obliged by a plan or description of a small smoking house.

REMARKS.

20th.—Dull but fair morning, few drops of rain at 9.30 A.M.; continued dull all day; fine night.
21st.—Bright sunny morning; rather cloudy in afternoon.
22nd.—Cloudy dull day throughout.
23rd.—Cloudy morning; sunny and bright afternoon.
24th.—Foggy and dark morning; sunshine at noon; fair and pleasant the rest of the day.
25th.—Fair day, rather cold wind, fine sunset, starlight night.
26th.—Dull morning, but fair pleasant day; slightly windy.
27th.—Fine week. High barometer, westerly wind, uniform temperature, and no rain.—G. J. SYMONS.

COVENT GARDEN MARKET.—FEBRUARY 27.

OUR Market remains the same, with no alteration except in hothouse Grapes, which are a point higher.

From observations taken near London during forty-three years, the average day temperature of the week is 50.0°; and its night temperature 31.5°.

TEA-SCENTED ROSES.

SETTING down to write about Tea Roses a man feels, or should feel, how difficult a task he has set himself; and feeling as I do my incompetency to handle the theme, yet also feeling that no one can love them more or can have paid more attention to Tea-scented Roses, I venture to offer a few remarks upon these lovely flowers.

I must own at the outset that I do not know that much fresh information can be given about them, for the simple reason that I know of no good new sorts. Marie Guillot, which is a comparative novelty, is almost worthless when grown out of doors. A grand grower, having most ornamental foliage, it only lacks strength to open its intensely double buds. Under glass I should expect this Rose to be almost perfection.

The older sorts still hold their own, and I see no chance of these being supplanted. Catherine Mermet, Marie Van Houtte, Madame Bravy, Devoniensis, Comtesse de Nadaillac, David Pradel, and the three Souvenirs d'Elise, d'un Ami, and de Paul Neyron, with Madames Willermoz and Trifle, Belle Lyonnaise, Jean Ducher, and Rubens, are the cream of the lot. Sometimes Homère may give you a fine bloom, but rarely, very rarely, one good enough for a stand. Niphotos, Boule d'Or, Madame Jules Margottin, and Reine du Portugal are too uncertain to depend upon, and Madame Margottin so rarely attains to good form that no dependance can be placed upon her to give a good bloom.

Of the Noisettes Maréchal Niel, Triomphe de Rennes, Céline Forestier, and Madame Caroline Kuster are the best, and always some good blooms may be gathered in the early summer and autumn from these, but to the best of my experience rarely from out of doors will they give you blooms for the great Rose shows. Cloth of Gold now and then, but at rare intervals, supplies me with a grand bloom, but it is a hundred to one that you get one for a show. Rêve d'Or, though very beautiful as a climber, has never substance enough for the exhibition; and the same may be said of another good variety—Solfaterre. Lamarque is a most useful climber, and quite distinct from all others. Of the Gloire de Dijon family Belle Lyonnaise is by far the best, and Madame Trifle comes next; but now and then the old Gloire gives us an astonishing good bloom.

The best stand of Teas that I saw during the year was that of Mr. Mitchell's of Piltown Nurseries at the Crystal Palace; the next best that of Messrs. Curtis & Co.'s at Exeter. The amateurs, however, showed remarkably well, particularly at Torquay, the National, and the Aquarium. At the Crystal Palace there was no class for amateurs for Teas—a great omission which I trust will be remedied next year. These flowers have been shown in better form this year than I have ever known them. The demand for Teas is so great that the nurserymen in England are unable to supply nearly enough.

Their cultivation is most easy; all that they require is a light rich soil, a sunny situation, and plenty of liquid manure. They do not, however, live long, and require

frequent renewing. I find it best to move them every year, examine their roots, and plant them in fresh soil. Unless this is done, the long tap roots throw up such innumerable suckers that the plants are impoverished.

Late pruning of a very slight character is what the plants require; but if the wood has ripened badly I find it best to remove it entirely, even though the blooming season may be deferred till the autumn, or even till another year. It is not at all a bad plan to tie a piece of bast round such blooms as Souvenir d'Elise and Niphotos to prevent the wind knocking the petals to pieces.

Earliest to bloom and the latest to depart the Tea Rose is invaluable in our gardens. It is indeed perpetual, and far more valuable for a garden flower than the Hybrid Perpetuals.—WYLD SAVAGE.

PROPAGATION BY CUTTINGS—HINTS TO LEARNERS.

THE first thing necessary for successful spring propagation is the possession of clean and healthy stock plants, and this leads me to say that half the so-called diseases of plants are greatly aggravated, if not brought about, by the unreasonable way the stock is wintered.

All softwooded plants should be continually growing at least a little if they are to be kept healthy; rapid growth is not to be encouraged during dark and cold weather, but if a plant which is not deciduous or very succulent remains for months, or even weeks, without progressing it is of necessity going back. Take Verbenas, for instance: these are often crowded by the score into a small pot and placed on some dry shelf exposed in turns to wind and sun, fire heat, and something akin to freezing. They become hard and tough so that little seems to hurt them, and when potted-on and placed under favourable conditions they supply a good few cuttings. But does anyone suppose that plants reared from such a stock produce as good results as the progeny of plants which have been treated in a rational manner? I say, No. One good healthy plant at this time of year which has never been stunted is worth a hundred of starvelings, and the only way I know to keep stock plants healthy through the winter is by allowing moderate root-room in autumn and treating them like live greenhouse plants.

I certainly know of no purple bedding plant yet which is superior to Purple King Verbena when it is well managed; but starve it either in winter or summer and it is a miserable failure. When well grown each plant of this variety is capable of covering 2 square feet by the autumn, and while it grows it flowers, but the moment it ceases to grow either from crowding or starvation it begins to go back. I do not recommend planting it 2 feet apart in the beds. My plants are large and strong when put out; they are placed about a foot apart, and every other plant is cut away carefully and invisibly by degrees, so as to keep the ground always covered and yet allow continuous development. There should not be an insect or a spot of mildew on the plants when they are put out, or failure will be almost a certainty. The soil should not be over-light nor over-rich,

but about the medium in both respects. A little manure water will be very beneficial after the plants have been flowering some time, and every flower should be picked off as it is fading, or seed will be produced in great quantity and debility will follow as a matter of course.

A propagating house has no advantages over any other warm house for striking most of the common bedding plants. The principal object to aim at is a tolerably even temperature somewhere between 55° and 75°; and for most small cuttings, such as *Verbenas*, *Petunias*, *Lobelias*, *Heliotropes*, &c., moderate light without direct sunshine, such as is afforded close to the north side of a low wall, is the best. The kinds of cuttings I have named, too, are the better for double covering—*i.e.*, they should be covered by a handglass or small air-tight frame in addition to the roof of the house.

The simplest and I think the best propagating frames are merely boxes with panes of glass laid on the top. I use nothing else, and I propagate several thousands of plants annually. My boxes are 2 feet 8 inches long and 1 foot wide; a portion of them are 8 inches deep, the others are 5 inches, and the glass is in two or three equal lengths. From 2 to 3 inches of rather light soil is placed in the bottom of the box rather firmly. I do not often use sand, but it is safer for beginners to use a little, spreading it about an eighth of an inch thick over the soil and making it even with a piece of board. If the cuttings are taken from a warm place, the soil in the boxes should be allowed to become warm also before they are inserted. It is best not to water, unless the soil is dust-dry, till after the cuttings are in and the box is placed where it is to remain, when it should have a copious supply from a fine rose, if sufficient to last till the cuttings are struck all the better. Only a few cuttings should be taken off at a time, and they should not be allowed to droop at all; for although they may afterwards strike root they will be longer about it, and will not be so even in growth as if they had never drooped. *Verbenas*, *Cupheas*, *Iresines*, and some others will strike root equally well from any part of the stem, and therefore to cut them at a joint is a waste of time and material; but most plants strike best when cut just below a joint.

The more leaves there are left on a cutting, provided it can be kept from flagging or damping, the sooner it will strike root. I do not mean that a large cutting with numerous leaves will strike quicker than a small one, but that if two cuttings are alike when taken off the plant, and one of them has more leaves left on than the other, the one with the greatest leaf surface, other things being equal, will be likely to root first. If flagging takes place, however, the results will be probably reversed. The base of the cutting should be made to rest firmly on the soil at the bottom of the hole (therefore it is best not to have the dibber too much pointed; it should be slightly larger in diameter than the cuttings), and the sand and soil should be gently pressed around the stem, leaving the cuttings perfectly upright with the leaves clear of the surface.

As I said before, all my small cuttings are inserted in boxes. The work is done under the roof where they are to remain. Each box as soon as it is filled is placed in position, well watered, and immediately covered with glass as nearly air-tight as possible. If the boxes are placed on the floor, not too close to the hot-water pipes and out of the reach of the sun as mine are, the glass will not require lifting even for a moment till the cuttings are struck. No dew is created where there is no fluctuation of temperature, and there is very little on the shaded part of the floor of a house, also there is little or no evaporation so long as the cuttings have no roots and they are closely covered, hence no necessity for watering or wiping the glass. Even cuttings of such as *Tree Carnations*, which take from a fortnight to three weeks to strike, do not require the glass to be once lifted till roots are emitted, then air is given very gradually, shifting the glass about a quarter of an inch at first, and in the course of two or three days taking it off altogether. If the house in which they are situated has to be ventilated during the day, it is best to commence airing the boxes in the evening after the house is closed, and gradually inure the tender plants to the air contained in the house before admitting them to taste the smallest whiff of the natural atmosphere untempered. If it is necessary to shift the boxes to another house or pit after the glass has been removed entirely, it is advisable to cover them from the direct outside air, be it ever so warm, while shifting them. Of course, many of the precautions I have recommended are not necessary when the season is more advanced and cuttings can be struck almost

anyhow, on a dung bed or even a window-sill. There are many who ridicule the idea of giving so much attention to little matters at any time, but such people are not found among the most successful cultivators; these find that their success mainly depends on attention to little matters.—**WILLIAM TAYLOR.**

VEGETABLE CULTURE.

CHAP. X.—THE PARSNIP.

THE Parsnip is a native of England, and is one of the most nutritious vegetables grown in our gardens. Some think that it succeeds best in a rich sandy soil, but the fact is it will succeed in any kind of soil provided it is not less than 18 inches deep. We have had as fine Parsnips out of a clay soil as any other kind; but what we most prefer is a soil which shows neither a predominance of clay nor of sand. In preparing the ground for Parsnips it should be trenched to its full depth of soil, whether that be 18 inches or 3 feet. Ground which was trenched and manured for the previous crop need only be turned over with the spade to prepare it for the Parsnips, and no manure should be given, as it sometimes causes the roots to fork and prevents them from being clean and straight.

The seed may be sown at any time from the middle of February until the middle of March, but it should not be sown later than this to secure a full-grown crop, although useful small roots are produced from seed sown so late as the end of April; but we never as a rule like to be later in sowing than the first week in March. Drills 1½ inch deep and from 15 to 18 inches apart should be drawn for the seed. As the plants will ultimately be thinned-out to 10 inches apart, the seed need not be sown along every inch of the row, but three or four seeds may be placed at every 10 inches. Less seed does in this way. After the seed is covered and the surface of the ground is made level with a rake, no further attention is wanted until the plants are quite visible above ground, when the Dutch hoe must be run through amongst them. The young plants should not be thinned until they are from 2 to 3 inches high. When the seed has been good and sown as directed they will come up in tufts. In thinning at first two plants should be left together, and when they are from 4 to 5 inches high the smaller of the two may be drawn out. This will leave the permanent crop in a good growing position.

About the beginning of November many of the leaves will decay, and it is just at this time that the crowns of the roots often decay also. This is about the only disease which affects the Parsnip. When the leaves are allowed to lie and rot on the crowns they can hardly escape decaying, but by clearing the leaves away, say once a week, during the time they are decaying, not one root in a hundred will rot at the crown.

In localities where the winters are severe a quantity of the roots should be lifted in November, be laid in an open shed for a few days afterwards to dry, and then be stored like Carrots amongst sand in a shed or cellar. If this is done carefully the roots remain as good for some months as if they were in the ground, but where there is not convenience to store them properly the best plan is to leave them in the ground; indeed, although we have storage room very often the roots are not lifted until the month of February, when it is necessary to clear them off to make room for other crops. Of course, a few should always be lifted when there is any indication of sharp frost or snow, as it is difficult to get the roots out of the ground then. When seed is bad and only a patch comes up here and there, the blanks may be filled-up by transplanting, as Parsnips when 3 or 4 inches high may be transferred from one place to another and do well afterwards. Work of this kind should only be done in showery weather in April or May. The two varieties of Parsnips best worth cultivating are *The Student* and *Hollow Crown*.—**A KITCHEN GARDENER.**

CULTURE OF MIGNONETTE IN POTS.

I HAVE at the present time in the conservatory four pots of *Mignonette* 4 feet 3 inches in diameter, and nearly 4 feet high. The plants were in full bloom three weeks before Christmas, and show no signs of going off yet. My treatment of them was as follows:—I sowed the seed in pans on the 1st of March, and kept them in the vinery until the seedlings were large enough to be shifted into 60-pots. I then moved them into the Peach house, giving them another shift when the roots reached the sides into 32-pots. When the weather was suffi-

ciently settled I placed them out of doors and shifted them lastly into their blooming pots (10-inch).

I found one or two things to be of the greatest importance—viz., never to let the plants get root-bound until before they are shifted into their blooming pots; to look them over daily to pinch out the blooms and to destroy the green caterpillars, which, if left unmolested for a short time only, will do much damage. The plants must be moved into the greenhouse before the first frost, and when the blooming pots are full of roots they should have manure water twice a-week. The soil I used was two parts loam and one part leaf soil.—F. JORDAN, *The Hill, Willey.*

SPARMANNIA AFRICANA—ANTS.

A CORRESPONDENT of your Journal remarks that the *Sparmannia africana* is useless as a bouquet flower. I have now in a room on the mantelpiece a large piece of it which is just going off; it was cut ten days ago, the buds having expanded in water, and the leaves are perfectly fresh. When in London bunches were often sent which remained quite good for a week. Mine I brought from Mentone, where it grows in large shrubs in the gardens.

Are the small black ants wrong in a conservatory?—[No, they are enemies of aphides.—EDS.]

DUKE OF BUCCLEUCH GRAPE.

As I have had much to do with this Grape I have been very much interested with the discussion on its merits and demerits which has lately taken place in your columns. I must say I never have been extraordinarily successful in its culture, but at the same time I believe I have been more fortunate than many with it. With me it has always had a tendency—I may say a strong tendency—to make wood, if I may call it so, only like an outside shell, all the rest being soft pith. I have seen wood of it which came from Clovenfords exactly corresponding with this. So that it is not solely with me its wood is formed of this unsatisfactory description.

Next there is not one shoot in six which it produces that shows a bunch. Some seasons it will only show a few, and in others not one. When the bunches are in their embryo state they sometimes promise to be very large, but it is a long time before the individual blooms are formed, and when these are visible it is observable that in six cases out of ten the bunches are blind at the point, only a few flowers about the shoulders forming berries. Again, in many instances only about half of the berries swell to their normal size, the other half only reaching half size, or often not that. Before they are fully ripe it is a most difficult matter to prevent all the finest of the berries from splitting, and if they do not do this there is still the small black spot which disfigured the Golden Champion so much to spoil their appearance, as there can be no denying that the Duke spots like the Champion, and the finer the berries the more they show it.

The only difference I have ever been able to see between these two Grapes is in the form of the berry. In habit of growth, manner of fruiting, and in general character in every respect, and particularly including blemishes or diseases, they are identical so far as my observation goes, and I know a good many have from experience arrived at the same conclusion.

I have endeavoured without prejudice to describe the true character of the Duke of Buccleuch Vine, and it may be inferred that the treatment necessary to grow such a variety successfully must be very particular, if not peculiar; and to my discredit be it said, after growing this Grape from its first appearance in public, I can tell no more now about what treatment will insure its perfect development than I could before I knew it. What is the good of me writing about it, then? Simply this, I know many blame their gardener for not being able to manage this Grape, and it is quite time it was definitely known that it is solely the fault of the Vine itself.

It may now appear that "COLUMBUS" has discovered the right way of growing it, and according to his ideas "steaming, damping, and syringing" are the blunders gardeners submit it to, and therefore failure is the inevitable result. But to show that this is not the "grand secret" I was fortunate enough to see the Duke at Clovenfords a week or two previous to Mr. Barron's visit in 1872, and I have no hesitation in saying it was splendid—much better than I ever saw it at any subsequent visit, and at that time the Duke was frequently

completely syringed overhead in the afternoon, and it was then bearing it with impunity, although the fruit was maturing fast; and it must be understood that this was no ordinary syringing, but a thorough washing by a great pressure of cold water through an indiarubber pipe, which I should imagine to be quite equal to syringing, steaming, and damping combined. But I do not think that one instance of managing a Grape well is a sufficient warrant to recommend it in such a paper as the *Journal of Horticulture*, nor do I think that having it fine in 1872 has anything to do with what it is now. We can remember how eagerly we went to Dalkeith to see the Champion and the sensation it made in London, but what can be said of its general condition now?—MARKET GARDENER, N.B.

FLOWER SHOWS AND JUDGING.

THE *Journal of Horticulture* is proving a good medium for Rose-growers generally, and exhibitors just now in particular, to discuss their grievances, &c., and well do they avail themselves of it; but have exhibitors in other classes no grievances to relate or suggestions to make before all the schedules are arranged for another season? I venture to answer in the affirmative, especially with regard to the fruit and vegetable classes. The plant-growers no doubt have their grievances, which ought always to be listened to, and where possible remedied, as on them depends in a pecuniary sense the success of most shows; however, growing exhibition plants is not in my line. To me, and I believe the majority of gardeners, the fruit and vegetable tent has always the greatest attraction. Here occasionally is to be heard much cavilling about the judges' decisions, &c.; in some instances, perhaps, with good cause, in others from purely imaginary wrongs. Englishmen are proverbially a grumbling race, and gardeners especially so, and I for one should like to have a grumble at a few apparent inconsistencies.

Why do not local societies when arranging their schedules take a pattern from the Royal Horticultural Society, and modify the prizes offered to suit the funds of their respective societies? The above Society offers prizes for two bunches of Grapes instead of three, and so good an example ought to be followed by large and small societies. It is especially commendable to those who from necessity offer very small prizes; for instance, "three bunches of black Grapes, first prize 10s.;" and, what is still more inconsistent, a "collection of fruit, ten dishes, two of Grapes allowed, the others distinct, first prize 20s.;" and a dish of Grapes, "to consist of three bunches," is the rule. I do not grumble so much at the amount offered as I do at the quantity required. If smaller quantities could be staged employers would have less cause to grumble, and the gain in the number of competitors would fully compensate for the reduction. If funds are low why offer prizes for single dishes at all (this remark applies more especially to the vegetable classes)? but substitute two collections of fruit, and also vegetables, to suit the class of gardeners in the locality; one for the "big guns," the other for the lesser growers.

Flourishing societies and companies might also take a lesson from the Royal Horticultural Society in the matter of staging collections of vegetables. Why insist upon trays when the vegetables would look so much better arranged upon plates? The latter plan is a great saving to exhibitors, and entails but little extra outlay on the part of the society. At some large shows near London plates are provided, and at the same time fine collections of vegetables are to be seen huddled into trays, and some with each variety partitioned off, after the pattern of a nail box.

Do societies when they offer prizes for collections of vegetables consider that every variety staged should be "in season?" If so they ought to intimate as much, and thereby prevent apparently unfair decision. At all events, until such a rule exists I do not consider that the judges are justified in taking little or no notice of Brussels Sprouts, Parsnips, Celery, Cardoons, &c., in September. The exhibitor stages them, thinking he has done well by so doing; but I know of instances where the judges thought otherwise, and awarded the prizes accordingly.

Judges also appear very inconsistent at times, awarding prizes to vegetables in some classes that the exhibitor would not think of sending in for his employer's table. "Mammoth" Cauliflowers always appear to be in favour in the exhibition tent, but not in the dining room. This was at one time the case with Cucumbers; now we have gone to the other extreme. Some first-prize Cucumbers that I saw last year appeared to

me to cut a poor figure alongside other better-looking but unnoticed specimens. I do not advocate specimens with the "handle" ripening before the point is fully grown. I simply say to judges, Do not go to the other extreme when judging simply because you have previously awarded prizes to monstrosities of the Marquis de Lorne type and are now convinced of the error of your ways.

I hope also to see a reformation in judging the Pine Apple. Why is there not a class for heavy specimens similar to that for Grapes? Too often overfed and overgrown specimens are placed before smaller and better examples—better because not grown out of character, and with more regard to the quality, which those overgrown fruits in my opinion sadly lack.—ESSEX EXHIBITOR.

JUDGING ROSES.

IT seems after all that there is no great difference of opinion about Rose-judging, with the exception perhaps of the plan proposed by Mr. Curtis, and we may all shake hands over it. I was glad to see Mr. Baker's remarks, and the only point in which I differ is with regard to knowing the names of the persons to which the Roses belong. I am in favour of open judging. Those who are at all familiar with the exhibition tent generally know by the writing on the cards of the names of the Roses, by the mode of setting up, or one thing or another, to whom the principal stands belong; and I think it would be far better to have open judging, and to try and secure only the services of those judges who are not biased by the names. My friend the "HEREFORDSHIRE INCUMBENT" does not like a code of rules issued by the National Rose Society to regulate judgment. I agree with him so far; no code of rules would do away with a judge's idiosyncrasy, nor do I think it would be wise to do so; but I certainly object to the names of judges being published under the idea that exhibitors should try to please the taste or fancy of the leading spirit among the judges. We all owe much to our veteran Macenas, certainly no one more than myself, in the matter of developing tastes and judgments with regard to Roses.

I cannot quite agree with Mr. Baker that only exhibitors are qualified as judges. Many like myself are, owing to soil, climate, and position, unable to take part in the leading south of England and Midland Rose shows as exhibitors with any chance of success, and do not care about figuring as champions in merely local country shows; and, though it may be somewhat the exception, there are many men of critical taste and accurate judgment, men, too, who can decide quickly and firmly, who have neither time nor means to exhibit, but who yet would be competent to act as judges. I am always in favour of three judges, and that certainly one should be a regular exhibitor and versed in the character of the new Roses as far as possible, in order to help to detect duplicates. There may be cases where duplicates are purposely placed in a stand, but in many instances it happens from carelessness or the similarity of the sorts, and I have often heard exhibitors and their assistants when staging their blooms ask whether this bloom is so-and-so or so-and-so, and the answer has been, "Oh, it is so very like, it will do." Close observers of the habits of growth, wood, foliage, shape of petal, &c., are not easily deceived, but when judges have to go over several stands of seventy-two or forty-eight trebles, it is not very easy to carry the eye from one corner of a stand to the other; and unless there has been a glaring error purposely committed, I would always give an exhibitor the chance of changing a disputed bloom.

I am apparently in the minority of one with regard to allowances for distance and travel. I would not, of course, allow a damaged stand to win over one that was uninjured, but, *ceteris paribus*, if the Roses had in themselves been intrinsically much better—and judges can generally tell both what has been and what will be—I am in favour of making the allowance for the superior stamp of blooms. My friend Mr. Pochin has often well explained it to me when he has said, "This might have been that, but that never could be equal to this." A small highly-coloured bloom half open will often attract the attention both of judges and bystanders, which in three or four hours of a hot tent will show that after all it was only a second-rate bloom. I can well remember one day, when judging with the Rev. Reynolds Hole at South Kensington, our having some doubts between the merits of two particular stands of Tea Roses, and he turned to a rosarian who happened to be passing, and he said, "Oh! I like that stand the best, they are much

more suited for the button-hole," upon which, when our friend was gone, we laughed and said, "Well, that helps us to decide the question, we must certainly give it to the other stand."

I am now brought to the question of Teas. Let them stand on their own merits, they generally have classes of their own. When well grown they are beautiful, and when put in merely because they are Teas to vary a stand they often help to break a stand down; and many a time at our principal shows at South Kensington, Crystal Palace, and elsewhere, the worst and least interesting stands have been Teas and Noisettes.

After all, in spite of the "HEREFORDSHIRE INCUMBENT's" warning of "*Quieta non movere*," I am inclined still to think a code of rules, not so much to tie or discipline judges as to regulate the public taste, issued by the National Rose Society would do good, and it would also be well if the same Society would give definite hints to exhibitors as to the time allowed for staging and clearing the tents, &c., and not to allow some exhibitors to go on arranging stands and coming in long after the time specified. No doubt there are difficulties at times about the distances boxes have to be brought and the unpunctuality of trains, but in such cases the secretaries ought to have notice beforehand, and the boxes should be arranged as far as possible before starting, so that but little should be required; but, as a rule, the exhibitors close at hand are the worse sinners, who try to stage all they can and make up their 48, 36, 24's, &c., after they get into the tents, when they have looked at other stands to see their comparative weakness or strength. An exhibitor tries to make up a 48, finds he is deficient, then changes it into a 36 or a 24, as the case may be, and is constantly moving his Roses from one stand to another, and when the time comes to clear the tent is still undecided. We certainly want the bump of order and punctuality more enforced, and exhibitors should not be allowed to place their boxes on the stage (unless the places are previously allotted) till they are quite finished. The final touches, which many exhibitors think help to guide the judges' opinions often lead to the errors of duplicates. I have known an exhibitor pretend to have left a budding knife under his stand, in order that he might come in to have a final finger in his box, and at minor shows blooms are borrowed from each other without apparently any compunction; but this, of course, deals with another and a wider subject. I remember, however, distinctly last year at a local show, after the judging was over, a lady saying to her gardener on going round the tent, "I did not think, B, we had a *Maréchal Niel* out." "No," was the answer; (*sotto voce*), "it was given to me this morning." I wish therefore the National Rose Society would not only submit some rules as to the points of merits in Roses, but help to give some hints to secretaries and committees as to the insurance of order, punctuality, and perfect honesty in exhibitors. As I said before, so I am still inclined to think—the real difficulty is not as to the laws or judges in the larger exhibitions, but as to the obtaining of qualified judges in the local shows. There are not, after all, many men able to form accurate and quick judgments, and I can certainly endorse Mr. Baker's concluding remark, in hoping that the best Roses may always win.—C. P. PEACH.

I HAVE read with great interest the discussion carried on in your columns during the last few weeks on this subject, some of which I am sorry to say I consider very impracticable; but of late the discussion has assumed a more practical form, and I allude more particularly to the excellent article in your last week's issue written by Mr. Baker, with whose remarks, with one or two exceptions, I entirely concur.

The first great secret undoubtedly is to appoint competent judges, and the men most qualified to judge Roses are practical Rose-growers; and managers or secretaries of provincial shows would do well to keep this in view. With all due respect to men who are most able general gardeners, I submit that unless they be practical Rose-growers as well they are not the men to judge Roses. During the last ten or twelve years I have been a very successful exhibitor of Roses, but during that time I have frequently fallen a victim to incompetent judging. I entirely agree with Mr. Baker in his suggestion of counting the strong and weak points in rival stands, for in nine cases out of ten that will satisfactorily settle the matter; condition as to general effect, brightness of colour, good foliage, &c., of course being taken into consideration. With respect to size, I think it ought to have a more prominent position than Mr. Baker gives it. I am quite ready to admit that a small good Rose is much better than a big bad one; but a big Rose that is not coarse and overblown is better than a little one.

During this discussion we have frequently had Paul Neyron quoted as the coarse type of Rose, which it undoubtedly is, and such Roses as Paul Neyron, Antoine Mouton, and a few others I could mention never ought, in my opinion, to be in a stand of Roses at all.

Again, as to Teas. Much as we value and admire them, particularly in large stands, it is absurd that they should receive any favour simply because they are Teas; the best blooms presented to the judges, be they Teas or Perpetuals, ought to win.

The last and most knotty point Mr. Baker touches upon is the duplicates, which at times will greatly puzzle both exhibitor and judge. The wood and foliage will in some cases decide the matter, but in others it will not; and a judge before he decides to act on such evidence ought to be very sure he is right. But in all such cases as these it would be well if some means could be devised of calling the exhibitor's attention to it and give him a chance to clear up the doubt. We are all liable to mistakes, and it is hard to have a good stand of Roses thrown overboard on such mere quibbles; for of all the thorns in the flesh of the rosarian defective judgment is the worst to bear. In conclusion, I am sure I only echo the opinion of all honest and conscientious Rose exhibitors when I say, Let us have Rose-growers for Rose judges, a fair field and no favour, and let the best man win.—W. NICHOL, *Drinkstone Park, Bury St. Edmunds.*

I QUITE agree with your correspondent "M. N. R. S." in failing to see why the points and point-card system advocated by "H. C." should be simply impracticable and a Quixotic idea. Surely "H. C." advocates the use of point cards only in cases of very close competition, and not that they should be dealt out to every Rose in the show, but to those closely competing stands the number of points of which must be taken down. I think the act described by him of placing the point card by each Rose as it is judged may be done as quickly and perfectly as it can be written down, which we have often been obliged to do very imperfectly on the backs of letters, &c.—R.

ROYAL HORTICULTURAL SOCIETY.

MARCH 5TH.

For the first time during the present year the meeting was held in the conservatory, and a brilliant day and many valuable collections of plants, also excellent contributions of Apples, Grapes, and Potatoes, rendered the gathering a very successful one. Plants were staged by Messrs. Veitch, Williams, Wills, Osborn & Sons, and some excellent groups from private growers.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P., in the chair. Mr. Joshua Atkins, gardener to Col. Loyd Lindsay, Lockinge Park, Wantage, sent three bunches of Black Alicante Grapes in fine condition. They were much admired, and received a cultural commendation. Mr. Mowbray, gardener to the Earl of Leven, Fulmer, sent three bunches of Alicante, but they were not so large as the former though in excellent condition. G. F. Wilson, Esq., sent a fruit of Theobroma Cacao, the seed of which produces the cocoa and chocolate of commerce. The fruit is like a short thick Cucumber; and the specimen was sent from Trinidad to Mr. Alfred Barret, Weybridge. A letter of thanks was awarded. Mr. Mowbray, gardener to the Earl of Leven, also exhibited a dish of Mushrooms well grown, for which a letter of thanks was awarded. Mr. Francis Dancer, Little Sutton, exhibited heads of the old Late Purple Cape Broccoli, a valuable hardy variety now very rare. It was a remarkably fine stock, and a letter of thanks was awarded. A very fine collection of Apples and Potatoes came from the garden of Mr. W. E. Hubbard of Leonardslee, Horsham. The former were in a very perfect state of preservation, and appeared as fresh as if they had just been gathered from the tree. Much credit is due to Mr. Ford, the gardener, for the way in which these were exhibited, and a silver medal was awarded to them.

FLORAL COMMITTEE.—Dr. Denny in the chair. The collection of Messrs. James Veitch & Sons consisted of a gorgeous group of Hippeastrums in a great variety of colour, also of a mass of the valuable Early Gem Rhododendron, lifted from the open ground the day previously. The Rhododendrons were surrounded with densely-flowered examples of the charming forcing shrub Spiraea Thunbergii, which was figured in our columns on page 181. Amongst the more striking of the Hippeastrums was Leopold, vermilion, one-third of the petals being tipped with white. Some of the flame-scarlet varieties were also intensely rich. A silver medal was recommended.

A similar award was voted to Messrs. Osborn, whose collection was composed chiefly of Palms intermixed with bright variegated-foliaged plants, the whole affording evidence of superior cultivation.

Mr. Wills's group was arranged in a free and artistic manner,

and the effect produced was excellent. The groundwork was composed of small Ferns and Lycopods, out of which sprung in a semi-natural manner such choice Orchids as Phalaenopsis Schilleriana, Odontoglossums Alexandrae and cirrhosum, Dendrobium Wardianum, Dendrochilum glumaceum, &c.; at the back were Azaleas under a canopy of Palms. A large silver medal was recommended for the group.

Mr. Williams staged a very beautiful group. A collection of Hippeastrums contained some extremely bright varieties, notably Aurora, intense blood red; Prince Arthur and Victorine were also very bright. A fine pan of Primula denticulata attracted much attention on account of its superior culture. A pan of Anemone fulgens was also very attractive. Mr. Williams also exhibited a few Orchids, also plants of his new seedling Azaleas of the Amœna type, to one of which, Wm. Carmichael, a first-class certificate was awarded. In colour it is purplish pink. The other varieties—Princess Beatrice, rosy lilac, and Mrs. Carmichael, rosy purple, were also exhibited. These are as free in flowering as A. amœna, but have much larger flowers and must be regarded as great acquisitions for early decorative purposes. A silver medal was recommended for the collection.

Messrs. W. Paul & Son exhibited ten boxes of cut blooms of Camellias in fifty varieties. These produced a most beautiful effect. The boxes of Fimbriata, Imbricata, Alba plena, Bealii, Princess Charlotte, white; Manara, soft scarlet, massive; Fatima, rose and white; Marie Louise, blush; L'Avenir, rose; and many others were excellent; and very beautiful were the plants of the white variety Ninfa Egeria; it is very free, and a great acquisition.

Mr. Aldous, florist, Gloucester Road, South Kensington, staged an attractive group composed of Lilies, Tulips, Azaleas, Palms, &c., and was awarded a vote of thanks.

A very fine group of Cyclamens was staged by Henry Little, Esq., Hillingdon Place, Uxbridge. Some of the darker varieties were extremely rich, especially one or two which were violet shaded with carmine. Some of the carmine selfs were also very superior, while the whites were pure. Mr. Little also sent a small group of Hippeastrums. A vote of thanks was accorded.

The most beautiful group, however, in the conservatory, although a small one, was contributed by Sir Trevor Laurence, Bart, Burford Lodge, Reading. The plants, which were composed of small Ferns, Isolepis gracilis, and grand Orchids, were arranged on the surface of a tub containing a large Araucaria, the Orchids depending also from the stem of the tree. The topmost plant was a floriferous specimen of Dendrobium litiflorum, beneath which D. Wardianum was still more striking by its hundreds of flowers. O. Alexandrae was represented by grand spikes, and the brilliant Sophronitis grandiflora had very large flowers. A splendid variety of Odontoglossum Rossii major was included in the group, and for which a cultural commendation was awarded. This beautiful group commanded much admiration, and the Committee recommended that a Lindley medal be awarded. The plants were grown by Mr. Spyers. H. G. Elliott, Esq., The Crescent, Doures Park Road, Clapton, staged three excellently flowered plants of Odontoglossum cirrhosum, for which a vote of thanks was awarded. Mr. R. Parker, Tooting, exhibited remarkably fine flowers of the sweet and beautiful hardy aquatic Aponogeton distachyum, also some early-flowering Megaseas (Saxifrageas).

Some beautiful hardy Primroses were exhibited. The one exhibited by Mr. G. F. Wilson at the last meeting named Scott Wilson was on this occasion awarded a first-class certificate. It is highly distinct, being of a violet plum colour with a sulphur eye. It is pin-eyed, but cannot fail to be valuable both for decorative purposes and as a parent for future beautiful varieties. Mr. Wilson also exhibited a flowering spray of Rhododendron præcox superbiens.

Mr. R. Dean had a similar award for a variety named Octoroon, intense velvety maroon with yellow eye; the petals are of good substance and very glossy. Also for Ealing Crimson, magenta-crimson, with yellow eye; a stout good flower. Mr. Dean also exhibited Chieranthus mutabilis, raised by Rev. Harpur Crewe. It is very distinct and peculiar on account of its variable flowers. Mr. Harrison Weir exhibited a pale blue Polyanthus, Blue Beauty, which is very pretty. B. Hook, Esq., Bridgefield, Reading, exhibited cut flowers of several varieties of Hellebores. They were very beautiful, and merited the vote of thanks awarded. Mr. Charles Turner, Slough, exhibited cut flowers of his new Tree Carnation, A. Alegatière. They were very bright and sweet. This will prove one of the most valuable of the class to which it belongs on account of its dwarf habit and free-flowering property. Messrs. Paul & Son, Old Nurseries, Cheshunt, exhibited flowers of the green-flowered Rosa viridiflora, also of the Galician Rosa Mundi, also a salmon sport from the double Azalea imbricata. Col. Trevor Clarke exhibited a plant of Ornithogalum narbonneense, a very pretty border plant. Messrs. Veitch & Sons had a botanical commendation for Epidendrum Wallisii, a singular species from New Grenada. They also staged Odontoglossum Jenningsii and a few other novelties, the most striking of which was Hippeastrum Sir Garnet Wolseley, vermilion-scarlet with greenish centre. Mr. J. J. Bowie, gardener to the Earl of Sandwich, Hinchbrook, Huntingdon, exhibited very fine Neapolitan Violets.

Mr. Ivory, Dorking, exhibited a seedling *Kennedy*, named *Iveryana*. The colour is a rich violet blue and is very effective. A few Orchids and some good varieties of *Imantophyllum* miniatum were sent from the Society's gardens at Chiswick.

Prizes were offered by "an amateur" for the best light and dark seedling *Amaryllises*. The first prize for light varieties was awarded to Mr. B. S. Williams for Mrs. Rawson, a variety with scarlet petals margined with white. A first-class certificate was also awarded to the variety. The second prize was withheld. Mr. Williams was awarded both the prizes in the class for dark varieties, first with *Fairstar*, a pure scarlet variety, the colour being continued to the base of the petals, which were of good substance, the flowers being medium-sized; and second to *Prince Teck*, vermilion crimson, the base faintly tinged with green, a small flower but very rich.

A self-acting ventilator termed the electric automatic ventilator was exhibited by Mr. W. Symonds, Guilsborough, Northampton. The model was ingeniously devised, and appeared to work smoothly and well. As soon as the thermometer attached reached a given point an electric current set the machinery in motion and opened the ventilators.

LECTURE ON THE FIG AS A STANDARD.—At the afternoon meeting, which was held in the conservatory, and was presided over by Lord Alfred Churchill, after Dr. Hogg had remarked on the subjects which had been submitted to the Fruit Committee, and Mr. Jennings had referred to some of the plants exhibited, Col. Trevor Clarke proceeded with the reading of the paper that he had prepared on the above subject. He first referred to the zone of Fig culture as standards in England, which was restricted to the seacoast and sheltered districts of the south. He had an impression, however, that the Fig was amenable to this mode of culture over a wider area of the country, and five years ago he tried the experiment with a tree of *White Marseilles* and one of *Brown Turkey*, which he planted in the open garden—a walled enclosure. The district he described as being in the centre of England, the soil being strong loam approaching to clay. So far from the position having special climatic advantages, the lecturer remarked that the reverse was so far the case that Peaches, Nectarines, and Apricots could not be relied on for producing crops on the walls, which in general were total failures. Yet the standard Fig trees ripened their crops perfectly, and in favourable seasons the wood was well matured, only the tips of gross shoots having been slightly injured by frost. Exposed trees of the varieties named produced crops quite equal to trees trained against walls; and his experience with other varieties led him to believe that a Fig orchard intelligently managed in the London district is an experiment well worthy of being tried. He referred to the sturdy short-jointed wood of standard Fig trees, which he attributed to a more equable temperature than prevailed near the surfaces of walls, also to the fuller exposure to the air all round, not in front only, of the branches. After referring to the different modes of pruning the Fig the lecture, which was listened to with much attention, was brought to a close. The acoustic properties of the conservatory are, however, not good, and the remarks of the several speakers were only imperfectly heard by a large number of the audience.

Sixteen new Fellows were elected during the afternoon.

NOTES AND GLEANINGS.

A MEETING of the General Committee of the NATIONAL ROSE SOCIETY was held at the Horticultural Club on Tuesday last, the Rev. A. Cheales in the chair, when the schedules as already arranged by the Executive Committee were adopted and ordered to be printed. They are of the most liberal and varied character, and it may fairly be anticipated that the Exhibition at the Crystal Palace will surpass in interest even that held at St. James's Hall. There will be two classes of subscribers, some at £1 and some at 10s., with corresponding privileges. The accounts for 1877 were finally accepted, and measures were adopted for the purpose of increasing the number of members, which it is hoped all lovers of the Rose will help forward. The rules for judging were considered and approved, but before finally submitting them they will be considered at another meeting. The greatest unanimity prevailed, and all seemed anxious to make the Society what its name professes it to be—the National Rose Society.

—As an instance of the mildness of the season several RHODODENDRONS in Sir Henry Peck's garden at Wimbledon House are flowering as freely as we usually find them in May. They have a striking effect in the pleasure ground. They are chiefly varieties of *Nobleanum*, and are represented by both light and dark colours.

—ALLUDING to the longevity of RASPBERRIES, "A KITCHEN GARDENER" states, in reply to "D. Deal," that he knows a place where many acres of wild Raspberries have

grown on the same ground for nearly a century, and they produce better fruit now than many he has seen in gardens.

— "R. M. A." has forwarded to us a flowering spray of the GHENT AZALEA EXCELENTE to show how charming it is both by its purity of colour and pleasant fragrance. Our correspondent informs us that his plant, which is nearly 3 feet in diameter and about the same in height, is extremely beautiful. These Azaleas, he remarks, continue in beauty much longer when made to flower early in the season than they do when they expand under the hot sun of late spring or early summer. We have forced this variety, which was raised by Mr. Van Houtte, and have proved its great value, as we have that of many others, for decoration in early spring. A. pontica var. Excellente has pure white flowers, the upper lobe being very pale yellow. The trusses and flowers are medium-sized, and the plant is very floriferous.

—A CONSIDERABLE number of Orchids are now flowering in Lord Lonsborough's celebrated collection at Norbiton. *Odontoglossums* are represented by *O. sceptrum*, distinct by its fimbriated sepals and lip; *O. Hallii*, very fine; *O. triumphans*, *O. Cervantesii*, *O. Andersonianum* (true), and finer than are many forms under this name, *O. hystrix alba* Dennisoni, *O. Roezlii*, several good examples of *O. Alexandræ*, also of *O. cirrhosum* just expanding. Amongst the *Dendrobiums* we noticed *D. speciosum*; *D. Wardianum*, a very fine variety just expanding; *D. crassinode*; *D. primulinum*, very chaste; *D. Boxalli*; *D. heterocarpum*, primrose-coloured and scented; *D. thysiflorum*, and the Australian species *D. Kingianum*, small, porcelain blue; and the singular Cobweb *Dendrobium teretifolium*. Just fading is *Cattleya Trianae Russellianum*, which is perhaps the richest of the section; and there are also some pleasing varieties recently sent home by Mr. Bull's traveller, Mr. Shuttleworth. *Helsia sanguinolenta*, a singular Orchid having a lip like the pretty aquatic *Aponogeton distachyon*, attracts notice, as also does the small and rare *Ornithidium coccinea* with its small coral-red flowers. *Epidendrum purum* when viewed at a distance almost resembles the Meadow-sweet. *Cypripedium hirsutissimum* is distinct and very fine, and *Dendrochilum glumaceum* is elegant and sweet. *Phalenopsis Schilleriana*, *Cymbidium eburneum*, *Phaius grandiflorus*, *Celogyne cristata* and its variety *Lemoniana*, and the small and bright *Oncidium cheiroporum*, the Wallflower *Oncid.*, also contribute to the early March display.

—As bright spring flowers for greenhouse and conservatory decoration the LACHENALIAS are well worthy of general culture. The most striking display that we have seen of these flowers is at Wimbledon House, and the mode of growing them adopted by Mr. Ollerhead is highly worthy of notice. They are grown in baskets, in the same way that *Achimenes* are often seen. The baskets are lined with moss and filled with soil. As the work of filling them proceeds during the summer bulbs of the *Lachenalias* are embedded in the moss, about two hundred of them being placed in each large wire basket. The baskets are kept moist by being dipped as required in a tank, and in due time an effect as novel as it is beautiful is produced. The growth of plants in the baskets is such as to resemble in form a candelabra, and the hundreds of spikes of orange-and-scarlet flowers show to great advantage at this period of the year. This mode of growing *Lachenalias* is within the reach of all having a greenhouse, and as suspended floral ornaments we do not know anything to surpass the brilliant baskets in question.

—A CORRESPONDENT asks if varieties of CYCLAMEN PERSICUM come true from seed. If they do, he considers it is just to award certificates to seedlings of superior merit; but if they do not, he fails to see the equity of honouring the *Cyclamens* while seedling *Cinerarias*, herbaceous *Calceolarias*, and *Pelargoniums* are precluded from receiving similar honours. We shall be glad to receive information as to the "fixity" of *Cyclamens* by seed.

CYPRIPEDIUMS AND THEIR CULTURE.

CYPRIPEDIUMS, or the Lady's Slippers, are amongst the most curious and useful of Orchids. They are valuable on account of the long time they keep in bloom; in fact, a good collection furnishes flowers all the year round. The length of time the flowers keep after being cut is remarkable. I have known flowers of *Cypripedium insignis* continue fresh for two months when placed in water in a room. *Cypripedium barbatum* and its varieties last fully three months in flower.

Cypripediums are natives of several countries, including

India, Mexico, Switzerland, North America, Java, and several others. Several valuable hybrids have been raised of late years in England, one of which is figured; it was raised by Mr. Dominy, who obtained it by crossing *C. Pearcei* and *C. caudatum*. Considering the wide geographical range of these useful plants a selection can be made for the garden, intermediate house, or stove, according to choice or convenience.

Cypripediums are easily propagated by root-division. Hardy sorts require a compost of turfy peat, loam, and charcoal, with a good mixture of broken potsherds, and a little sand well incorporated. They should have a cold frame to protect them from the heavy rains and frost.

Intermediate sorts require nearly similar compost, adding a little chopped sphagnum moss. *C. insigne*, *C. villosum*, *C. ve-*

Fig. 28.—*CYPRIPEDIUM DOMINIANUM*.

nustum, &c., belong to this section and require a temperature not below 40° and not above 55° by fire heat; air should be admitted freely on all mild days.

Stove Cypripediums require a compost of sphagnum moss, charcoal, fibrous peat, a very little loam, and broken potsherds, mixed well together; the sphagnum moss should be cut up with a pair of shears. In potting, the crowns should be kept an inch or two above the top of the pots, the surface being rounded to give a neat appearance. The pots for all kinds should be filled three parts full of crocks.

The plants require a liberal supply of water, but the chill should always be taken off it before using. They do not require syringing during the winter months, but in spring and summer they should be syringed lightly twice a-day and have a

good watering twice a-week. When the plants are in flower support the flower stems by thin green-painted stakes. Such Cypripediums as *barbatum* can when blooming be taken out of the stove and be placed in the conservatory, where the flowers, being shaded and receiving more air and less moisture and heat, will continue in beauty much longer. *C. niveum* can likewise be taken out of the stove when in flower. *C. Lowii* should not be taken out, nor should the newer sorts, for they nearly all require heat.

In selecting Cypripediums care should be taken to choose those most likely to be of most use for the cultivator. If an Orchid house is provided it will be more easy to select, and the new varieties should be included; but those most likely to give satisfaction in a mixed collection of plants are *C. insigne*,

C. caudatum, *C. villosum*, *C. venustum*, *C. niveum*, *C. barbatum*, *C. superbum*, *C. giganteum*, *C. Roezii*, *C. Lowii*, and *C. Sedeni*. I have named such as are moderate in price, easily grown, and suitable for commencing a collection.—D. L.

NOTES ON NORTH DURHAM AND NORTHUMBRIAN AMATEURS AND FLORISTS.—No. 2.

GLADIOLI.

MR. BATTENSBY grows his Gladioli in new loam, leaf soil, and cow dung, to which is added bog peat. This compost is spread on the ground about 4 or 6 inches deep, and dug-in in the autumn, and is forked over frequently during the winter. The corms are allowed to break in a warm greenhouse, and when they have grown about half an inch long they are planted. The first lot is planted about the last week of March, and last the second week in April. The corms are planted about 4 inches deep, the beds are mulched with horse droppings when the shoots are about 6 inches high, and liquid manure made from stable urine and horse droppings well diluted with rain water is applied twice or thrice a-week until the flower stems appear, and once a-day afterwards. Mr. Battensby has great faith in two-year-old seedlings, which invariably produce fine flowers the third year. For shading, boxes 2½ or 3 feet long and 8 inches inside with glass fronts and tops are employed. These are fastened to a stake, and by means of a wedge can be lowered or raised as may be required. These are an invention of his own, and could be made for about 18s. per dozen.

The following are two dozen varieties which Mr. Battensby considers well worthy of cultivation, although they are not new:—*Adolphe Brongniart*, rose, flamed red; *Benvenuto*, orange red, white spots; *Eugène Scribe*, soft rose, flaked red carmine; *Figaro*, light orange red, white stains; *Horace*, scarlet and white blotches; *Lacépède*, rosy violet, tinted white; *Le Thane*, fiery red; *Horace Vernet*, red purple, white stains; *Jupiter*, light red, flamed purple; *Madame Desportes*, white, striped violet; *Marie Stuart*, sulphur white, blazed cherry; *Meyerbeer*, red, flamed vermillion; *Milton*, white, tinted rose; *Monsieur Legouvé*, fine red, white lines; *Orphée*, rose, flamed carmine; *Emperor Napoleon*, orange red, stained white; *Prince of Wales*, brilliant red, white spots; *Princess Mary of Cambridge*, white, carmine spots; *Pactole*, yellow-tinted rose, dark blotch; *Madame Furtado*, rose, flamed carmine; *Shakespeare*, white, flamed carmine; *Rosa Bonheur*, white, tinted lilac; *Robert Fortune*, red carmine, white lines; *Velleda*, rose, lilac stain.

But Pansies and Gladioluses are by no means the sole occupants of this amateur's garden, for Mr. Battensby cultivates vegetables and plants as well as florists' flowers. He has raised a new Potato, which he calls the *Axwell King*, a cross betwixt the *Lapstone* and the *Victoria*. It is very handsome and prolific, and so far has been perfectly free from disease.

His plant stove, which is a neat and commodious structure of about 40 feet long and 12 feet wide, is well filled with specimen and half-specimen plants of *Allamandas*, *Stephanotis*, *Bougainvillias*, *Lorax*, *Dipladenias*, all strong and good, many of them having figured conspicuously at most of the local shows. This house he has made in his leisure hours, doing both the brickwork and setting the hot-water pipes and boiler. He has also a greenhouse of about the same size as the stove, containing a magnificent example of *Erica Marnockiana*, 3 feet high by 5 feet through. This is truly a marvellous plant, perfect in health as well as symmetry and shape; also a splendid *Erica Devoniensis*, 3 feet by 5; and *E. Shannoni* and *E. Austiniana*, 3 feet by 2; *Phacocoma prolifera* Barnesii is 4 feet in diameter, and there are two good plants of *Lapageria rosea* and a smaller and healthy specimen of *L. alba*. A good collection of show and fancy *Pelargoniums* is also noticeable. In speaking of his stove plants we accidentally omitted the following novelties of recent introduction:—*Croton Andreanum*, *Cocos Weddelliana*, *Gleichenia rupestris*, *Davallia Mooreana*, and a few others.

Mr. Battensby is a thorough enthusiast in each and every department, and considering the limited time at his disposal it is perfectly astonishing how well everything is cared for. He has nearly half an acre of kitchen garden, which is well stocked with fruit trees and also three hundred or four hundred Roses, which form quite a superb collection, as he purchases the cream of the new varieties of each year. The borders are also well filled with herbaceous flowers, which he exhibits, while the squares are occupied with Potatoes, Peas, Cauliflowers, and Onions, which are all grown for the exhibition table.

Mr. Battensby's family inherit his enthusiasm, some of them watering while others are hunting for slugs in the summer evenings, and when arranging and cutting his flowers for exhibition he can send any of the family for a flower, whether it be a *Pansy* or *Rose*, each will come to him true to name. This in children not yet out of their teens speaks well for the ardour which pervades the enjoyers (for work is to them real enjoyment) of this noteworthy amateur's garden. In future notes I will refer to some *Carnation* and *Picotee* growers.—B. C.

KEEPING GRAPES.

I BELIEVE that the keeping of Grapes is more due to the condition of the fruit itself than to any external causes. That condition, in my opinion, is well-matured fruit with a good covering of bloom, which is mainly the result of proper culture and good management. A good bloom acts, I think, as a preservative to the Grapes; by being insoluble in water and of a resinous nature it resists the action of dew, and thereby renders the fruit less liable to decay from condensed moisture, which is so prejudicial to the keeping of Grapes. As a proof of this dew-resisting property of bloom, take for instance a Cabbage covered with bloom, and on examining the leaves on a dewy morning or after a fall of rain the water will be all found to be standing in globules on the surface, the fine glaucous powder being impervious to wet. This theory, if correct, would account in some measure for the Grapes keeping so well at *Drumlanrig* under so changeable an atmosphere, as the Grapes there, everyone admits, are of first-rate quality, and consequently well fortified against decay from condensed moisture by an impervious coating of bloom.—ALPHA.

THE CULTIVATION OF THE VERBENA.

I COMMENCE preparations in the spring by planting out in a bed by themselves as many *Verbenas* as I think will be necessary for stock plants. I give them plenty of room and let them grow and flower until the middle of August; I then cut them back to within about 6 inches of their roots, and if the plants are at all crowded in their centre I thin out the shoots so as to permit free access for sun and air to the plants. I then spread over the ground some decayed manure from an old hotbed, and fork it in just deep enough to bury it. If the soil is at all dry I apply water freely, as it is of the utmost importance to secure a free healthy growth. On this depends the future well-being of stock. By the end of September I obtain strong cuttings, but when making them I am not at all particular about cutting them at a joint, as I think that quite unnecessary; in fact I think it is an advantage to cut them between the joints, as more leaves can often be secured, which is very important in striking softwooded plants.

My mode of striking has always proved most successful, for I rarely lose a single cutting. I take a box or pan about 4 inches deep, drain it with crocks, and over them place some moss or coarse peat and then 2 inches of silver sand pressed down firmly and watered. In about two hours afterwards the cuttings are dibbled in as firmly as possible, then sprinkled and placed in a pit with slight bottom heat. The cuttings are shaded from bright sun for a few days, and the sand is always kept in quite a moist state. I use no bell-glass, but on the contrary give plenty of air, and in about ten or twelve days the cuttings are rooted. This I think is one of the most critical times with the *Verbena*. As soon as rooted I take them out of the sand and pot them into small 2½-inch pots, for if left in the sand the roots become elongated and hard and they will never make good plants. When potted off I keep them in the same temperature as they were struck in for about two weeks, giving plenty of air and shading from bright sun for a few days.

I never water my *Verbenas* with pure water, but always with tobacco water. I believe that tobacco water is a great stimulant to the *Verbena*. I have grown them successfully for several years and have used nothing else, so I attribute my success in a great measure to the tobacco water. Three years ago I grew fifteen thousand; I was then living in a commercial place, and stronger and healthier plants it would have been impossible to have found. I have had no mildew, green fly, or thrips since I have adopted this mode of culture. Although I use tobacco water I always fumigate once a week, as I like to be on the safe side, as prevention is better than cure. The way I use the tobacco water is this: After the cuttings are potted off I commence with tobacco water in a weak state

about the colour of pale sherry, and gradually increase its strength at every watering until it becomes the colour of very strong tea. I always use the sprinkler for plants in 2½-inch pots, but when they are in 4-inch pots I dispense with it. I am quite sure anyone who will like to try my plan will have fine healthy stock plants and plenty of good cuttings. I always keep the stock plants in a cool house or pit about 40° and pot them in rather poor soil. I do not commence propagating for spring plants until February or even later if I have sufficient stock plants to take cuttings from. Cuttings struck in March make fine plants if grown as I have described.

I am quite convinced that so many people fail in the cultivation of the Verbena because they start wrongly, taking up old plants after they have been flowering all the summer; such plants must naturally be exhausted, and the consequence is they produce poor spindly shoots, and cuttings taken from such plants are especially liable to disease. I always keep my Verbenas as near the glass as possible.—W. B.

SEASONABLE NOTES ON VINE GROWING.

A LETTER from a correspondent "TED" contains questions on subjects of interest to amateur Vine-growers generally at this season. "TED" planted a number of young Vines in the spring of 1876; each Vine bore a bunch that year. Last year the rods were cut back to about the bottom of the rafter before being started, and during the season each Vine made three strong canes. The Vines are planted 3 feet 9 inches apart, and the canes are trained 1 foot 3 inches asunder. "Are they too close?" asks "TED." The reply is, They are much too close to remain for the permanent well-being of the Vines. Overcrowding is one of the most common errors in Vine-growing, and the mistake of overcrowding of the foliage is not confined to amateurs, but is not unfrequently indulged in by professional gardeners.

For the first year or two when Vines are young and vigorous they will push almost through any impediment from overcrowding, but they eventually sustain injury and show it by their gradual decrease of strength in making weaker shoots year after year, eventually producing spindly bunches or none at all. It has been proved times without number, that no tree will make healthy growth from half-ripened wood, and it is contrary to all reasoning to suppose that fine crops of fruit will be produced under conditions where the growth by being overcrowded cannot become matured. Canes growing 15 inches apart cannot develop their shoots without covering each other. As a rule Vine shoots bearing fruit cannot be stopped shorter than 18 inches to give two joints beyond the bunch, consequently the shoots from one rod not only crowd on the shoots from the next rod but overlap the main stems of each other. All Vine rods when young should be at least 2 feet from each other, and "TED" will find it much more satisfactory if he trains only two canes up from each Vine instead of three. All Vine rods closer than this should be cut out at once. If the Vines have commenced growing, the sap may be prevented from oozing out after cutting if a good quantity of joiners' knotting is daubed into the cut.

"TED's" Vines have just commenced showing leaf, and every bud is emitting two shoots. Many Vines do that, and very often every shoot that appears is allowed to grow, which is another and very sure way of overcrowding. As a rule when the shoots are from 2 to 3 inches long it can be seen which are going to produce the finest bunches. When there are two or three of them together rub off every shoot excepting the one bearing the best bunch. Have no hesitation in doing this, as it is the very best that can be done for the Vines. Young short-jointed canes often require disbudding too, as the shoots should not be left on them closer than a foot apart. "TED" will do well to attend to this, and six bunches will not be too many for each rod. All other bunches excepting these should be removed, but not until the berries have been formed, then cut off those which may not have formed properly and in sufficient quantity to ensure good bunches; but when only one shoot is left to each eye the shoot from which the bunches have been removed must not be cut away, but stopped and not allowed to grow further than 1 foot from the main rod. Never leave more than one shoot to a bud or spur as a rule, and do not leave the shoots closer than a foot on each side of the cane. All shoots at that distance from each other should be left, whether they are bearing fruit or not, as they will be required to form spurs when pruned to produce shoots annually.

All Vines may safely be started into growth now; but little

fire heat should be employed, in fact it need never be used for the first three weeks or a month after the ventilators are closed unless the outside temperature falls below 40°. Vines which have had a foot or 18 inches of new soil placed on their roots throughout the winter as a top-dressing will derive much benefit from having dung and leaves to the depth of 18 inches placed above the fresh soil, as it has a tendency to draw the roots into the new material.

"C. P. P.," page 145, thinks cow dung is not so lasting, and consequently not so good for Vine borders as horse and pig dung. Pig manure I have always found very hot, and it must be used with very great caution. Further than this I have nothing to say against it. It makes nourishing liquid manure, and in this state we use a large quantity of it. About horse dung being more lasting in its effects than cow dung I have great doubts; but I have no doubt at all about it being decidedly inferior to cow dung for Vine borders. I fancy "C. P. P." cannot have understood fully the risk he might lead many to incur by employing horse dung. Had I no other manure than this in making a Vine border I would keep it out altogether and make the border without manure, because extensive practice amongst Vines and Vine-border-making has satisfied me that there is nothing that can be put in the border that will produce fungus quicker than horse droppings: and it is equally well known that nothing is more injurious to the Vine than fungus at the roots. A few years ago I saw a number of vineries which had been recently planted near Manchester. During the first year every Vine made most satisfactory growth, but the second year many of them refused to grow at all, and on examining the border it was found that the roots had been poisoned by fungus generated from the horse dung extensively used at the time of making the borders.

"C. P. P." also objects to what he terms my "laying down the law too definitely." I did not think I had done so, especially as in the remarks he refers to I stated that "many little details which may be found necessary are omitted here, but all the most important points are included and may be applied with a little addition or reduction, according to circumstances." Is this a definite law? His suggestion as opposed to mine may be considered merely as a matter of opinion.

To return to "TED;" if he has any fear that his Vines have grown too much for the superfluous rods to be cut out with safety, let him rub the whole of the shoots from every third cane and train the laterals of the rods remaining at the distances above recommended.—A KITCHEN GARDENER.

THE CHRISTMAS ROSE AND OTHER HARDY FLOWERS.

I DO not remember ever seeing the common Christmas Rose so fine as it is this season. Many of the individual flowers exceed 3 inches across, are of the purest white, and on stalks from 6 to 9 inches in length. Two years ago, about this time of year, I collected a few large plants, which were pulled to pieces, making in all over three hundred young plants to start with. These were laid in on a border which had been liberally dealt with. Last spring they were treated to a sufficiency of rich material, and this present winter and spring they are fully repaying us for the extra attention given. In the course of a few weeks the entire lot will be lifted, the larger plants divided and again planted, but this time into narrow beds to allow them to be more easily reached for cutting the flowers. I am well aware it forms part of our common gardening creed that Christmas Roses should not be disturbed, but, like many other commonly received opinions, when tested by results there is no good reason to be found for it. A large plant of *Helleborus atrorubens* is even of more value to us in the way of supplying cut flowers than *H. niger*. It was divided at the same time and treated in the same manner, and will also be lifted and the largest plants again divided. This has been taken for a Passion-flower over and over again when presented in a cut state, and certainly there is no Passion-flower more attractive than this Hellebore. I have the care of a good selection of hardy plants, but none of them do I like better or find of more use than *Helleborus atrorubens*. By simply denuding the flower stalks of everything but the flower these stand perfectly well.

Other hardy flowers most excellent for filling glasses, and which are producing bloom in any quantity, are Hepaticas of numerous sorts, none being better for our purpose than the single white, dark blue, and pink; Crimean and double Snowdrops, the satiny *Sisyrinchium grandiflorum*, *Arabis alba*,

which will continue to flower well into summer, and Violets, the best of which is Czar; Queen Victoria is larger, but the flowers do not open well here. We have also others, but Czar is our mainstay.—R. P. BROTHERSTON, *Tynninghame*.

ECHEVERIA RETUSA.

THE generic name was given in honour of M. Echeverri, the artist who produced the beautiful drawings of the "Flora Mexi-

cana." The specific name, *retusa*, refers to the form of the old leaves, they being rounded at the end and depressed in the middle.

Perhaps no plants became more suddenly popular than Echeverias when once the "ice was broken" and it was seen how admirably many of them were adapted as edging plants in flower gardens. Their close rosette-like habit of growth and their fleshy glaucous leaves imparted a distinct feature to flower gardens in summer, and gave a finish to the beds

Fig. 29.—ECHEVERIA RETUSA.

such as no other plants could effect. No sooner were they employed in the parks of London than they secured public appreciation, and it became necessary for gardeners far and near to obtain and increase a stock of the coveted "Succulents." Eventually whole beds were planted with fleshy-leaved plants, some of which are as stately in form as others are close and

compact in their habits; indeed, it was the character of growth rather than the beauty of the flowers that was the chief source of attraction possessed by this class of plants.

The species figured is an exception to the general rule that Echeverias are cultivated because of their distinct forms of growth and fleshy foliage, for *E. retusa* is primarily grown on

account of the beauty of its flowers, and the plant is justly regarded as being additionally valuable because these flowers are produced during the winter. So popular has *E. retusa* become for winter decoration that large numbers of plants are now prepared by trade growers for supplying Covent Garden Market. These plants are esteemed as window ornaments by dwellers in towns, and they are equally suitable for furnishing the stages of greenhouses and conservatories in country and suburban districts. The flowers are very bright yet extremely chaste, and the effect of well-grown examples of this *Echeveria* are quite dissimilar from any other plants flowering at the same period.

The most useful plants are those grown and flowered in 5-inch pots, and when such plants have five or six flower stems, supporting in the aggregate nearly or quite one hundred orange-red and yellow flowers, a display of no common order is produced. The plants are readily propagated by leaves or cuttings, and are easily cultivated. A rather rich loam containing a liberal admixture of charcoal or any gritty substance forms a suitable compost. Where moderate-sized plants are produced they will, if planted out in rich soil in a sunny position in May, make fine flowering plants by the autumn, when they should be potted before they are touched by frost. No plants lift better from the open ground than these, but they must be taken up soon enough, for frost turns the foliage brown and heavy autumn rains promote its decay. The plants continue in beauty for a period of several weeks. The calyx of the flower is divided into five unequal green spreading lobes, the corolla being also five-parted; it is much longer than the calyx, and is orange red externally, the interior margins of the segments being yellow. The flower stems grow about 8 inches high, and seldom need stakes to support them.

Echeveria retusa was received by the Royal Horticultural Society in 1846 from their collector Mr. Hartweg, who discovered it growing on rocks near Anganguco in Mexico.

A PLEA FOR AMARYLLISES.

CONSIDERING the great beauty of these plants it is to be regretted that they do not receive more attention. In bulbs, particularly Amaryllids, we possess some of the most lovely and sweetest of flowers. Immortalised since the time of Solomon, it is remarkable that these plants are very meagrely represented in gardens. I allude not to the different genera of the order Amaryllidaceæ, but to the genus *Amaryllis* in particular. True, we find a few of the *Amaryllis* or *Hippeastrum* *aulica* type, but none, except in rare instances, of the very fine varieties that owe their origin to the Messrs. Veitch and other raisers, many of which varieties are as great advances upon the species as are to be found in *Pelargoniums*. Why plants of such great and distinct beauty should be neglected I could never make out. I grant that they have few leaves when flowering and little or no perfume, but the flower scapes above a carpet of *Fera fronds* have a truly gorgeous effect. The flowers for cutting are particularly valuable from their rich glow and bright distinct markings. Indeed, there are no greater ornaments for decorative service than Amaryllises, the pots not being difficult of concealment, as the scapes are borne on stout stems at a distance from the bulbs, which renders any disadvantage of foliage practically imaginary. Some kinds, however, have foliage along with the flowers, there being no reason why by hybridisation a race of perfectly evergreen Amaryllises should not be raised. We have *Hippeastrum pardinum* with foliage almost as persistent as *Vallota purpurea*, which, by the way, is not any more perfumed than a majority of *Hippeastrums*, yet no one would care to be without the Scarborough Lily in quantity. Upon the same ground no objection can be taken to *Hippeastrums* on the score of perfume not being present. They are in winter and spring months what *Vallota*, *Belladonna*, and Guernsey Lilies are in late summer and autumn—viz., indispensable; in fact they are even more useful, not infrequently flowering in autumn and again in spring. This tendency to second bloom is very marked in *H. pardinum*, which possesses also this distinct feature—it improves with age. As the bulbs increase in size they increase in size of flower, in the number of scapes, and in frequency of flowering. I am convinced that this class of plants will become popular, and that we shall have them as highly perfumed as an *Eucharis* and in a still greater variety of colour; and I hope to see *Vallotas* at least striped if not snowy white, with the perfume of the Guernsey and *Belladonna* Lily, and flowering more than once in a season.

I do not know how many scapes a bulb may be made to produce in a season; but strong bulbs will afford two, succeeding each other, and this without any apparent exhaustion, but contrariwise increased vigour. It is clear, however, that exhaustion speedily follows seed-production, and the ripening of seed should therefore be avoided; indeed all plants are more enfeebled by the perfection or even partial development of the seed vessels than by an excess of bloom, which points to the removal promptly of the seed vessels of all plants immediately the flowers fade if the after well-doing of the plants is important.

There is no greater error committed in bulb culture than that known as the drying-off process. Amaryllises dislike drought at the roots. I, like many others, thought a complete rest absolutely essential, and kept them dry after the growth was complete. It certainly caused a loss of a majority of the roots, often necessitating the placing of the bulbs in a hotbed to induce them to start. Now the very reverse is practised; and I strongly advise those who have hitherto tried the drought system of ripening to never allow the soil to become dry—that is, if they care to have scapes as long and as thick almost as walking sticks with corresponding umbels of large flowers. Bottom heat is quite unnecessary. I keep what few plants I have on shelves 18 inches to 2 feet from the glass, the shelf being suspended so that the foliage can spread itself all around and be fully exposed at all times to light, which I think essential to the vigour (and upon which depends the free-flowering) of the plants. From the shelf they are withdrawn only for flowering, and are immediately afterwards replaced, so that leaf-growth may be made in the full light. The foliage is then moderate in amount, but is gracefully arched and leathery, of a deep green colour, and with which the bulbs increase quickly in size. They are watered very freely during growth, and having the benefit of the usual sprinkling twice a-day and damping at noon, the watering being continued until the foliage shows evidence of ripening, for many of the varieties cast the leaves when the growth is perfected, but some retain the foliage; but not one that I have examined shows any diminution of root-action. Certainly no loss takes place, if the soil be kept moist, from going to rest and starting into growth. In fact I have frequently turned the plants out of the pots and found the roots as closely matted as a crested ball. They are kept moist, and yet very much less water is required when at rest than when growing; but there is very little difference, nevertheless, as to moisture, only it is required less frequently.

They are grown in 7-inch pots, and are not potted more frequently than when the removal of offsets necessitate, or the soil becomes wasted, as it very often is, by worms. This potting is done directly after flowering. The old soil is simply removed without injury to the roots, and the offsets being removed with roots there is opportunity to make some reduction of the ball, in which case the parent plant may be returned to the same size of pot, or, if larger bulbs are wanted, the plants are not infrequently too large for being transferred to the same size of pot without a wholesale destruction of roots, which is undesirable, in which case it is preferable to transfer to 8 or 9-inch pots; but I prefer to keep them in the 7-inch, and as many as possible in 6-inch, which may generally be accomplished by the removal of the surface soil and picking-out that at the sides of the ball. Good drainage is necessary. Yellow loam rather heavy than light is a suitable compost. Liquid manure during growth is better than enriching the compost with manure, which speedily decays and leaves the soil loose, these plants requiring a firm soil, their roots "feeling" the sides of the pots, and then they grow sturdy, form large firm bulbs, and give immense scapes of bloom, unsurpassed by any other class of bulb requiring a stove temperature. They do well, however, in an intermediate house, and are deserving of very much more attention than has hitherto been accorded them.—G. ABBEY.

GLEANINGS FROM GLASNEVIN.

EVEN at the dulllest season there is always something to interest and repay a visit to Glasnevin. The year is yet in its infancy, and vegetation generally only as it were awaking from its repose; but early as it is, anyone in quest of floral beauty will find there examples of it in the open as well as under the glazed roof and in the artificial climate of stove and greenhouse. The noble specimen of *Arbutus hybrida* which stands on the grass lawn in front of the Director's

house, its every spray terminated by a pendulous panicle of pale waxy flowers, is just now a beautiful object. So, too, a little further on, is a goodly specimen of *Rhododendron præcox*, simply a mass of flowers. The Tree Heath (*Erica arborea*) is garlanded with its pearly bells; the lovely *E. carnea* is in full flower, as is also the rather rare white variety of it. More interesting than any of the three, to the lover of our native flora at all events, are the lowly bushes of Dr. Moore's remarkable variety of *E. mediterranea*, which have been for several weeks past in full bloom, and exhaling an agreeable fragrance.

In the way of bulbous spring beauties, besides the abundant white and gold of the "first pale blossom of the unripened year," and the yellow Crocus, the kindred but far prettier Snowflake, of which we were gratified to see numerous patches in the borders, and the lovely *Iris reticulata*, are very attractive. Some of the Hellebores are still in condition, notably *Helleborus purpurascens* and the stately *H. orientalis*. White and purple patches of *Iberis*, *Arabis*, and *Aubrietia*, yellow bosses of *Alyssum olympicum*, and rosy-flowered cushions of *Saxifraga oppositifolia* serve to brighten-up the herbaceous quarters. Leaving the outside ground, and turning into the cool conservatory which flanks the Palm house on the west, we found it particularly gay and attractive, several magnificent Himalayan *Rhododendrons* being in flower, notably two well-marked varieties of *R. argenteum*, the branches crowned with gorgeous heads of huge creamy white flowers, also the white-flowered variety of *R. arboreum* and *R. barbatum*, with flower heads as remarkable for their compactness as for their dazzling brilliancy.

Both the Orchid house and greenhouse are gay with many flowering specimens, and in the stove conservatory that grand old plant *Astrapea Wallichii* has just ceased blooming, and its many pendant tassels, though no longer gleaming with colour, told that the bloom had been unusually profuse.

We were much gratified at meeting a specimen of that grand Myrtaceous tree *Syzygium Moorei*, which the Director of the Melbourne Botanic Garden has described as presenting when in full bloom "one of the most gorgeous spectacles imaginable, its every branch and even part of the stem clothed with one mass of royal purple blossoms, having the appearance of rich pale velvet." This grand flowering tree is specifically named in honour of Mr. Charles Moore, brother of Dr. Moore, and Director of the Botanic Garden, Sydney, from whom the specimen at Glasnevin was received. Until we saw it there on this occasion we fancied it had not yet been introduced to Europe. It was further gratifying to us to learn from Dr. Moore that he has received a supply of seeds of another beautiful Myrtaceous tree—*Eucalyptus ficifolia*, of whose floral charms the Melbourne Director, in his report for 1876, speaks in still more glowing terms.—(*Irish Farmers' Gazette*.)

NOTES ON VILLA AND SUBURBAN GARDENING.

IN the hedgerows the silent progress of spring is visible. The Violets and Primroses are lifting their ever-welcome heads, while the Hazel bush is conspicuous with numerous weeping catkins, which contrast with the miniature female flowers of the most intense scarlet. There is also a murmuring of life in the air which a few weeks since could not be heard—the song of the thrush and blackbird—all reminding us that we must be up and doing, and that the busiest month of the whole year is with us; and everyone who values March dust will not lose any time in forwarding any gardening operations still left undone, but be ready to take advantage of weather suitable for sowing and planting.

Peas sown now will oftentimes be ready to gather within a few days after those sorts that have stood throughout the winter, and good varieties for present sowing are William I. and the well-known Champion of England. William I. is a green Marrow Pea of a hardy constitution, combining both earliness and flavour, and is remarkable for its productiveness. It is a Pea that is fast becoming popular, and is highly suitable for amateurs, as it does not require sticks more than 3 feet 6 inches in height. Champion of England is still one of the best blue wrinkled Peas we have, but requires sticks from 5 to 6 feet; it is also a most productive Pea of the very best flavour. Draw out shallow drills about 3 inches deep and sow the Peas moderately thickly, but even and regular, along the drill. Merely drawing the soil over them is all that is necessary unless birds are troublesome, then old fish nets or Pea-protectors should be employed. Birds do most damage to Peas just as they are sprouting through the ground, so at this season of the year it is well to place on the protectors at the time of sowing. Broad Beans for a full crop should also be sown in rows 2½ to 3 feet apart. Broad Windsor, Seville Longpod, and

Monarch Longpods are good sorts for present sowing, but the Seville does not succeed in cold districts. The main crop of Onions must be sown as soon as the ground is in proper condition. On very light soils we find it best to sow during February, but on heavier soils sowing should be deferred until the ground is in a loose friable state. In all cases select an open space that has been deeply dug or trenched and well enriched with manure, and sow in drills a foot apart and about half an inch deep, raking the surface smooth after sowing. On very light soils when the ground is dry it may be made firm with a light garden roller. Sow the White Spanish for first crop, and Brown Globe and James's Keeping for later supplies. Make further sowings of Radishes Wood's Early Frame and French Breakfast, and of Lettuces Paris White Cos and All the Year Round Cabbage. A good breadth of Parsley should also be sown in shallow drills a foot apart, thinning out if the plants come up too thickly. Summer Spinach is frequently sown between the rows of Peas, but when sufficient room cannot be allotted to a breadth of Peas sow the Spinach in rows a foot wide, and gather the young leaves for use as soon as large enough. The thinnings may also be cooked, merely twisting the young roots off. Give abundance of air to Cauliflowers and Lettuces growing under frames and handlights to harden them sufficiently for planting out; and lay Potatoes out thinly to sprout in a steady manner for planting towards the end of the month.

Apricots, Peaches, and Nectarines that have had their branches removed from the walls for the purpose of retarding their fruit blossoms as much as possible must now be nailed in their positions at once. The branches must be handled very carefully, or considerable damage may result from rubbing off the almost bursting fruit buds. All fruit trees on walls are generally speaking very promising. The almost total failure of the fruit crop during the past season has given the trees a season of rest, which has enabled them to form an extra proportion of fruiting wood; and if a genial season should follow, or sufficient protection can be afforded them throughout their setting period, an abundant supply of good fruit may be anticipated. Many kinds of protectors are extemporised, glass copings being perhaps the most effectual. Covering with canvas and old fish nets is frequently resorted to, accompanied with more or less success; and even a few spruce branches hung over the trees have at times been the means of saving a crop which otherwise would have perished from inclement weather during the time the fruit blossoms are open.

Roses.—The result of the mild season is now conspicuous amongst Roses of all kinds, in fact many of them have made over an inch of growth already; taking their activity into consideration we should advise that they be pruned without delay, even if it should in some cases be a week or ten days before the time usually recommended for performing this important operation. If pruning is delayed after this time the Rose bushes, from their activity, will receive a check that they will scarcely get over throughout the season. Gloire de Dijon and such-like strong growers only require the weak and dead wood removing, and the strong and gross shoots fastening to the trellis or framework to which they are attached. Hybrid Perpetuals should be pruned to two, three, or four eyes, according to the habit of the variety, always cutting the shoot back to a prominent out-looking bud. Remove the weak shoots from the centre of the plant if very bushy, care being taken to leave an open and well-balanced head. We prefer an ordinary pruning knife for pruning Roses, but we have known some amateurs do the work better and quicker with a pair of sécateurs. In certain cases with dwarf Roses it is a very good plan to peg the branches down, merely cutting the tips of the shoots away; this plan for covering beds or banks can be highly recommended, and we have seen very fine blooms result from this laying or pegging down. As the work of pruning proceeds have all the prunings gathered up, and let the ground underneath, on which a mulching of manure was laid as previously advised, be dug-in; this will make everything fresh, and give a neat appearance to the beds.

Conservatories and Greenhouses.—These structures are now becoming gay with numerous forced flowers. Hyacinths and Tulips are now coming into bloom in a natural way, and must have abundance of water and stakes placed to them directly the flower spikes emerge above the foliage, otherwise the weight of their heads will cause them to bend over and perhaps snap off.

Bedding plants, such as Verbenas, Petunias, Lobelias, Coleuses, Alternantheras, &c., can now be propagated very freely, and will strike readily in a moist temperature of 70° to 75°. Pot-off without delay all Geraniums that have been stored in pots or boxes, keeping them close and warm for new roots to form, and cut down any old straggly plants that were lifted from the beds in the autumn; the tops will make excellent cuttings, and may be grown into fine plants for autumn blooming.

WORK FOR THE WEEK.

KITCHEN GARDEN.

DUE regard having been paid to the manuring, trenching, or digging of vacant ground for the reception of seed crops generally, it will now be in good tilth. The sowing of Onions in cold

localities may be deferred a fortnight longer provided the ground is not in good order; but the sooner they are sown the more likely are fine well-ripened bulbs to be formed. Reading, White Portugal, Brown Globe, and James' Keeping are excellent. Lose no time in sowing Parsnips and a good breadth of Early Horn or Early Nantes Carrot; a few James' Intermediate may also be sown, but defer the main sowing of Carrots for winter use until next month. Leeks sow in the open in drills 12 inches apart, and thin the plants to 6 inches asunder, the thinnings being capital for soups. A bed of Leeks ought to be in every cottage garden for spring use, they being very hardy—Musselburgh is first-rate. Lettuce sow in the open; we take a row in the alleys between the Onion beds, thinning-out the plants to a foot distance apart. All the Year Round and Neapolitan in Cabbage kinds, and Bath Cos Sugarloaf, with Alexandra Cos, are fine for this and subsequent sowings through the summer. Sow Turnips on an east border in drills 9 inches apart, thinning the plants to 6 inches. Early Snowball, Veitch's Red Globe, and Golden Ball are excellent varieties; the latter, having a yellow flesh, is not in such repute as the white, but it really is one of the best-flavoured Turnips. Radishes, sow from this time forward every fortnight or three weeks, French Breakfast, White Turnip, and Short-top Long Red. Make a sowing of Peas of such kinds as Dr. Maclean, Maclean's Wonderful, Dwarf Prolific (Prince of Wales), Best of All, Veitch's Perfection. For all kinds of medium height 4 feet is a sufficient distance between the rows, sowing a row of Round Spinach between each two rows of Peas, or if too much of this vegetable would be produced for the demand Radishes may be sown between the rows of Peas, they and the Spinach in no way interfering with the Pea crop. Tall main-crop kinds are represented by Culverwell's Prolific, Duchess of Edinburgh, and Emperor of the Marrows. Sow Broad Beans, Monarch Longpod and Improved Windsor. Earth-up the autumn-sown crops, also earth-up and place sticks to the early crops of Peas as required. Plant Seakale, also Horseradish in good well-manured light soil. Seakale which has been forced and afterwards hardened-off in a shed with the roots in moist sand may now be planted out. The crowns from this planting ripen early for forcing another year. Plant a good breadth in favourable localities of early Potatoes; in cold and northerly districts defer planting a fortnight or three weeks. Myatt's Prolific, Veitch's Ashleaf, and Fenn's Early White Kidney are superior in cropping, but are a few days later than the old Ashleaf. Unsprouted second earlies may be planted, but we prefer sprouted sets planted at the end of the month or early April in cold localities. Lapstone, Rector of Woodstock, and Snowflake are good both in cropping and quality.

Forcing Department.—Sow Celery for the main crop in gentle heat, but immediately the plants appear remove them to a cold frame or cool house, keeping them near the glass. Major Clarke's Solid Red, Williams' Matchless Red, Sandringham Dwarf White, and Wright's Giant White, are good sorts. Sweet Basil and Marjoram for early use may be sown in gentle heat, the plants when large enough to be pricked off into boxes; also sow Chervil in boxes if that in the open ground has not stood the winter well. Maintain the supply of Asparagus, Rhubarb, and Seakale by the introduction of fresh roots. Gently forcing the crops in the open ground, however, gives finer produce than that had by taking up the roots. Old roots of Rhubarb which have been forced may, after having been hardened off, be divided and planted out in rich soil, and in two years they will be strong enough for forcing again. Potatoes in frames, Radishes, Carrots, and Lettuces give due attention to in ventilating, and watering with weak liquid manure if needful, at a temperature of 65°. Early Potatoes will be tuberizing, and must not want for moisture until they are of a useable size, when keeping rather dry will do much to improve the quality. Those having pits, frames, or ground vineries may profitably employ them in the producing of early Potatoes, which plant forthwith. Nothing is so annoying as a break in the supply, and not infrequently a blank occurs between the forced and outdoor crops. Lettuces in frames planted in autumn are coming in; first in the race is Early Paris Market, closely followed by All the Year Round and Stanstead Park, with Bath Cos Sugarloaf and Hicks' Hardy White Cos to follow. They not infrequently suffer for want of water; weak liquid manure with the chill taken off may be given between the rows. Ventilate these and all crops of like kind in cold frames or under handlights whenever opportunity offers, drawing by want of air or timely thinning being fatal to profitable and high-quality produce. Endive wintered at the foot of walls may be blanched by an inverted flower pot with the hole stopped, or pantiles laid over the plants. Seakale in the open ground will be had by covering the crowns with inverted flower pots, stopping the holes, and covering with any light material, such as dung and leaves. Chicory may be blanched in the same way, cutting off any green tops, not too close to the crown. Sow Mustard and Cress frequently. Keep the pods closely picked from Dwarf Kidney Beans as they come fit for use, affording the plants water and liquid manure copiously.

HARDY FRUIT GARDEN.

Various methods of protecting fruit blossom and the tender young fruit and foliage have been previously enumerated, there-

fore we have only to point that if an expectation of a crop of fruit is to be ensured the requisite material must be provided and prompt application of the same made every evening after the blossom shows colour until the safety of the crop is manifest. The necessity of letting down the canvas, &c., may not be very apparent early in the evening, but the sudden and great fluctuations of temperature take place most frequently shortly after dark or shortly before daybreak, the latter, though of short duration, often in the absence of protection being such as to destroy the crop. The pruning of Cherries, Gooseberries, and Currant trees on north walls is not infrequently delayed from press of work to the last. Let it and nailing-in be proceeded with, and as these descriptions of trees are subject to attacks of aphides, to the disfigurement of the fruit, dress them with tobacco juice holding in solution soft soap 1 lb. to gallon of water.

FLOWER GARDEN.

In mixed gardens flowers are not confined to summer, nor graceful forms to tender exotics. Happily we have flowers for all seasons; from the Winter Aconite and pendant bells of the Snow-drop new beauties unfold in rapid succession, fragrance filling the air to repletion. Alpines and Ferns should now be trimmed, which in the case of alpines will be restricted to reducing such clumps as are too large, replacing any blanks with fresh plants, removing any decayed growths that may have been left as a sort of protection, adding fresh compost to such as require it. In the case of Ferns all dead fronds should be cleared away, the soil stirred around the plants, and a dressing of peat applied, strong-growing kinds having a preference for leaf soil. In forming a fernery positions in the shade and under the drip of trees are not uncommonly chosen, which is very unsuitable to the smaller Ferns, and the stronger growers suffer from drought in summer through the soil being kept dry by the roots of the trees, and the drought beneath large trees is fatal to the well-doing of the Ferns. Sheltered shady nooks should be chosen for a hardy fernery. An alpinery, on the other hand, should be in the open exposed to every breeze, having its slopes, ledges, crevices facing every point of the compass, which will afford sites for a greater variety of plants than those with one aspect only. In the case of large rockeries we have seen Ferns associated with alpines, the Ferns occupying the northern and such shady nooks on the east and west aspects as were suited to them, being intermixed with alpines, as Alyssums, Iberises, Aubrietias, Anemones, Campanulas, Lithospermum prostratum, &c., which among small-growing Ferns impart a lively appearance; indeed, we think such arrangements more pleasing than those less diversified.

Dahlia placed in heat as previously advised will now be affording plenty of cuttings, which taken off with a heel, potted singly in small pots, strike readily in a bottom heat of about 70° to 75°. The general stock of tubers should be examined, any decayed parts being removed, but they need not be started yet. Continue the propagation of such bedding plants as are short of the quantity required. *Salvia patens* is a good old plant. Roots now placed in heat will give cuttings shortly, which strike in gentle bottom heat; plants are also readily raised from seed sown in a hotbed. Insert without delay cuttings of such subtropical plants which are not raised from seed.

FRUIT HOUSES.

Vines.—Start the houses intended to afford fruit in August onward; indeed, Muscats, Alicante, Lady Downe's, and other late sorts should be encouraged to move now, as the fruit keeps much better when ripened in August or early in September than when the season is more advanced at the ripening period. Vines, however, which have only been recently pruned should not be started for some time yet. In the case of inside borders they should be brought into a thoroughly moist state by the application of water at a temperature of about 80°. It will in some degree stimulate the roots and compensate for the lack of fermenting material, which can do little good after this; indeed, no advantage accrues to the roots from an application of fermenting material to outside borders when artificial heat is not applied internally before March. The atmosphere should be kept moist by damping the rods and every available surface two or three times a day, 50° being a sufficiently high night temperature, and 65° by day with sun. Vines started early in December will have the fruit thinned and swelling freely. The border must not lack for moisture, which should be applied at a temperature of 80° to 85°, liquid manure materially assisting in the swelling of the berries. The outside border must have the fermenting material replenished as required. The sprinkling of the Vines should cease with their coming into flower, but a moist atmosphere must be maintained by keeping the evaporation troughs filled with guano water, a pound to twenty gallons of water; employ the same for sprinkling the paths in the afternoon. Vines started early in last month will be breaking, and will require attention to disbudbing and regulating the shoots as they advance, raising the temperature to 60° at night; on cold mornings it may fall to 55°, 65° by day from fire heat, up to 75° or 80° with sun.

Peaches and Nectarines.—Attend to the tying and regulating of the shoots as they advance in the earliest house, syringing morning and afternoon to keep red spider under, but if the pest obtain

a footing dislodge it by syringing with some approved insecticide, or a solution of soft soap 2 ozs. to the gallon of water. In the second house tying-in and disbudding must be proceeded with. The fruit, having had a considerable thinning after setting as before advised, will only require moderate thinning now, it being highly prejudicial to Peach and Nectarine trees to allow all the fruit to swell and reduce the number at once to a small quantity. Thinning, like disbudding, requires to be done gradually. Some kinds have twin fruit, as Noblesse and Grosse Mignonne: remove all such. The blossoms have set very thickly this year so far, and upon a shoot of 9 to 12 inches in length are a dozen or more of fruit, which we thin so soon as the blossoms are cast, removing the smallest fruit, that on the under side of the branches and the badly placed, leaving three to five upon a branch of the length named, which are reduced when the size of marbles to two, and afterwards to one, though both may be allowed to remain if there be a deficiency in other parts of the tree. When the fruit is of the size of walnuts the temperature may be raised to 60° to 55° by night, 65° by day from fire heat, and 75° from sun heat. If brown aphid appear fumigate two nights consecutively, being careful to have the foliage dry or the leaves will be blistered. There is no need to start the latest house, as the blossoms of Royal George are fully expanded; therefore no syringing must be practised, but keep the floors, &c., damped morning and afternoon, leaving a little air on constantly at the top of the house, employing as little fire heat as possible, but after the stamens appear a certain amount of warmth is needed, as we find that when the flowering extends over a considerable time that the blossoms do not set well; therefore, after the blossom opens maintain a night temperature of 60°; 5° lower in frosty weather in the morning will do no harm, and 55° by day up to 65° with sun. In the case of weak trees having a superabundance of blossom it will be advisable to remove those flowers from the under side or back of the shoots, as the trees may be against front or back trellises. Keep the borders in a thoroughly moist state.

Figs.—The earliest trees forced in pots swell their fruit best by having liquid manure applied, and being weak it may be given whenever watering is necessary. Syringe twice a day, not only to keep down red spider, but to maintain moisture in the house, which is so requisite to healthful growth in bright weather. Temperature 65° to 60° at night, 70° to 75° by day, rising to 80° at closing time. Attend to stopping the shoots and thinning those of trees planted out and started early last month. Overcrowding the shoots prevents the swelling and ripening fruit at a later period from receiving a proper amount of light and air, and renders the trees unfruitful. The pruning and dressing of the trees in late houses should be completed.

Cucumbers.—Increased light and solar heat will cause an increase of evaporation, therefore the atmospheric moisture must be increased or thrips and red spider will make speedy havoc of the foliage. The evaporation troughs should be kept filled with liquid manure, and the foliage be damped early on bright afternoons. If any of the above pests are visible remove the worst infested leaves, fumigating gently for the thrips, painting the pipes for the red spider with flowers of sulphur made a cream with milk. Sponging the leaves with soft-soap water is not advisable, as from the bruising and scorching which often results the remedy is worse than the disease. Better apply the syringe freely, as water is the best antidote to insect attacks. Keep young growths tied down, thin-out superfluous shoots and deformed fruit, stop at the first joint above the fruit, remove nearly all male blossoms, well thinning-out the fruit of young plants, and do not allow the fruit to hang too long, as it weakens the plants. Liquid manure may be applied once or twice a week. Keep the bottom heat at from 80° to 90°, top heat 70° at night, admitting air at 75° up to 90° as a maximum from sun, closing at 85°.

Melons.—A bed being in readiness, place a little soil all over the surface of the dung and a bushel of soil in each light, raised in a hillock with a flattened top, about 8 inches deep and well firmed down, planting when it is found that the bottom heat will not exceed 90°. Sow for succession at such intervals as the requirements of the establishment determine as to quantity. The bottom heat in houses must be kept at 80° to 90°, top heat 70° to 65° at night, 75° by day, admitting a little air at that, rising to 85° with sun and closing at that, and if an advance be made to 90° all the better. Sprinkle the house and plants in bright weather morning and afternoon, and be careful not to overwater, yet not allowing the soil to become too dry.

Orchard House.—Trees growing in pots and placed in their summer stations should be placed upon bricks if not wanted to root into the soil. Water will require to be repeatedly applied to have the soil thoroughly moistened to the base of the pots. Those trees planted out should have a good soaking with water slightly higher in temperature than that of the house, mulching with short manure lightly. Ventilation should be given very freely in mild weather, night as well as day; but in bright weather close early and admit air before the sun has raised the temperature considerably. Cold frosty weather prevailing whilst the trees are in bloom the ventilators must be kept close day and night; but in

the case of Peaches and Nectarines a heated house should be provided—indeed, all fruit houses should have means of preventing injury to the blossom and young fruit from frost. Aids to the fructification of the blossom are the shaking of the trees rather sharply so as to distribute the pollen, or the setting will be greatly assisted by applying the pollen to the stigmas with a camel-hair pencil. Good as are those aids, well-nourished blossoms are of far more consequence, and to be such they require warmth for their complete development and a well-ventilated atmosphere. Orchard-house trees, from the cramping of their roots in pots and restricting the growth by stopping, have, as a rule, very little growth beyond fruit buds now coming into bloom. A good thinning of the blossom is often as essential to a good set as thinning the fruit afterwards is essential to have fine highly-flavoured fruit. Overblossoming means a bad set; it exhausts the trees in the same way as overcropping. Thin the blossoms, especially upon weak growths, removing the smallest buds or blossom as the case may be. Keep a strict look-out for aphid, fumigating unless a majority of the blossom is expanded, in which case it is not safe to fumigate; but the aphid may be destroyed by applying tobacco juice with a brush to where the insects cluster upon the wood. There need, however, be no aphid if the house be thoroughly fumigated before the blossoms expand, the trees having been dressed in winter; nor any scale, which yields to soapy solutions.

TRADE CATALOGUES RECEIVED.

Wm. Clibran & Son, Oldfield Nursery, Altrincham.—*Catalogue of New and Choice Plants and Seeds.*

Francis & Arthur Dickson & Sons, 106, Eastgate Street, Chester.—*Catalogue of Select Farm Seeds.*

James Yates, 29, Little Underbank, Stockport.—*Catalogue of Vegetable and Flower Seeds and List of Gladioli.*

Samuel Yates, 16 and 17, Old Millgate, Manchester.—*Descriptive Catalogue of Vegetable and Flower Seeds.*

Edward Webb & Co., Wordsley Stourbridge.—*Illustrated Catalogue of Farm Seeds.*

TO CORRESPONDENTS.

*** All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

CORRECTING THERMOMETER (A. W.).—If you send the instrument to the Director of the Observatory, Kew, you can have it corrected. A moderate fee is charged, the amount of which you can ascertain on inquiry when you forward the instrument.

BLASTING LARGE TREE STUMPS.—"Puddle" asks for directions how this is done.

KEEPING NUTS (G. F.).—We know of no other mode of preserving nuts than in alternate layers with sand in earthenware jars, and those kept in a cold cellar.

PLANTING CUCUMBERS (A. Room).—The distance depends somewhat on the size of the trellis intended to be covered. We usually plant about 18 inches apart, stopping every alternate plant closely to obtain a few early fruits, permitting the other plants to grow more freely and attain strength before bearing heavily. As these, the permanent plants, cover the trellis those stopped more closely are removed after the few early fruits have been cut from them.

CELERY (W. B.).—Seed of the variety you name can be obtained from any of the leading seedsmen advertising in our columns. Its price is a shilling per packet.

STEP LADDER (W. F. Farquhar).—We do not know where you could get working drawings of the ladder, but we think that any carpenter could make it from the illustration.

PARINGS OF HORSES' HOOFES (L. F. O.).—You could not have a better manure for a Vine border than the parings of horses' hoofs and the droppings collected in a forge.

ROSES (William).—The Manetti is so called from an Italian professor of that name. Noisette is named after M. Noisette, a noted Rose-grower who lived at Paris. Celina is fanciful, and may be complimentary to some lady.

ANTS IN GREENHOUSE (F. H.).—The ants are not preying upon your Cinerarias, but upon the green fly with which they are affected. A sponge saturated with treacle and water forms a good trap for ants, which enter the sponge; they can then be destroyed by immersion in hot water. A saucer containing a little raw meat or partially picked bones attracts ants, which can then be destroyed. They, however, do more good than harm to plants in a greenhouse, unless they form nests in the flower pots.

CYCLAMEN (J. L.).—It is small and inferior to many already sold by most florists.

WEEVIL (H. B. Poynton).—The beetle you enclosed is the *Curculio picipes*. It is a well-known pest in the vineyard, and commonly called the Pitch-coloured Weevil.

HARDY RHODODENDRONS FOR LANARKSHIRE (Old Subscriber).—John Waterer, crimson; The Grand Arab, bright crimson; Geranioides, rose with

dark blotches; Erectum, deep pink; Mrs. John Clutton, pure white; The Queen, delicate mauve; Minnie, white with chocolate spots; Zuleika, delicate blush; Sir Thomas Sebright, rich purple; Catawbiense, light purple; Alarm, scarlet with white centre; Old Port, deep crimson.

NORTH WALL (H. Wood).—The Morello Cherry might be kept low enough. We know of no other fruit tree so suitable.

DISSOLVING BONES (Idem).—Bones require half their weight of sulphuric acid for their dissolving.

ROSES FOR A SHADED POSITION (An Anxious Amateur).—In your garden facing the east, and shaded from afternoon sun, you may plant any Roses except the delicate Teas. Try the following by way of a beginning:—Gloire de Dijon, Baronne de Rothschild, Charles Lefebvre, John Hopper, La France, Jules Margottin, Paul Neyron, Sénateur Vasee, Marquise de Castellane, Charles Lawson, Common Moss, Boule de Neige, Comtesse d'Oxford, Centifolia rosea, Abel Grand, and Alfred de Rougemont.

TREATMENT OF PAMPAS GRASS AFTER FLOWERING (G. M.).—You have done quite right to apply a "good manuring" now. Cut down the old blossoms and stalks as soon as they become unsightly, but do not touch a single blade of the Grass while it is alive. Cutting it off prematurely weakens the plant. Experience has taught us that the health and vigour of this Grass is invariably in proportion to the depth and richness of the soil in which it is planted.

FERNS WITHERING WHEN CUT (Tixeront Grange).—It arises from the plants having been grown in a moist, close, and shaded atmosphere. Ferns for affording cut fronds should be grown in a light airy position; and though a brisk heat may be necessary to secure the growths at an early season, it is desirable that the plants be hardened off in a lower temperature before cutting. We always immerse ours when cut for a short time in cold water, colder by several degrees than that in which they were produced; but the main point to be attended to is to grow them in the light so that the fronds may be firm in texture. There is a great difference in rooms for the endurance of cut flowers and Ferns. Our dining-room flowers last about twice as long as those in the drawing room. Coleus sprays keep best when the parts are soft or young; old parts have the stems too firm to imbibe water rapidly enough for the evaporation taking place by the leaves, but they may be restored from flagging by sprinkling them with tepid water and covering them up close for a few hours, a little of the stem being cut off before again placing them in water.

SOUVENIR DE LA MALMAISON CARNATION (Flora).—It is important that strong layers be rooted as early in the season as possible, the plants afterwards being grown in a cold frame, and subsequently in a very light greenhouse. They require rather strong and rich soil, such as is afforded by a mixture of two-thirds of turfy loam and one-third of very much decayed manure. Drain the pots well, and keep the plants scrupulously free from green fly and other insects. Directions for growing Carnations are in our "Garden Manual," price 1s. 6d., free by post for twenty postage stamps.

CAMELLIA LEAVES GUMMY (Gardens).—The glutinous matter on the foliage is caused either by insects on the plants or on some other plants above them, or it is an exudation from the leaves. In either case it is injurious, inasmuch as it causes dust to accumulate and forms a suitable nidus for the spread of the black fungus. Every leaf should be sponged, using a warm solution of 2 or 3 ozs. of soft soap dissolved in a gallon of water. After the foliage has been washed quite clean, both on the under and upper surfaces, the plants should be thoroughly syringed with clear water. If syringing is continued once or twice a day throughout the growing season, and the plants are in good soil and kept moist at the roots, they cannot fail to improve both in beauty of foliage and in profusion of flowers.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

FIELD CULTURE OF POTATOES.

UPON farms situated near towns, railway stations, or otherwise favourable for the sale of potatoes we consider them one of the most profitable crops which can be grown, seeing that it is not only a paying produce but economical in other respects, because if properly managed it is the most cleansing crop that we have in field culture, leaving the land in an excellent state either for barley or wheat. The latter we have grown on mixed loamy soils alternated with potatoes for seventeen years in succession, with sometimes stubble turnips after the wheat fed off by sheep, the potatoes being planted early in the following spring. With respect to the culture of potatoes in the field, the nearer it approaches to garden culture the better, except, however, using the plough instead of the spade. Land intended for potatoes should always be cultivated in the autumn whether foul with couch or otherwise. We often find on loamy soils a few bunches or tufts of couch grass, which it is best to fork out just previous to ploughing the land in the autumn, then plough a good depth and allow the land to lie all the winter without further work. In early spring if any lumps of couch make their appearance we then fork them out as before, after which the land will require but little or no horse labour beside the ploughing at planting time, and this plan commends itself because the manual labour is so much the cheaper than horse tillage. If, however, the land is found to be very foul in the autumn a regular course of fallowing

must be gone into. Ploughing or rather raftering the first thing, which is half ploughing, then scarify across the ploughing and remove the couch by continuous harrowing, rollings, &c., but we prefer to draw the couch away to heap or spread on meadow land instead of burning, simply because it may be got rid of with less work, and without hindrance if the weather is showery, which also enables the further work to proceed more quickly. After the fallowing or rather cleansing is completed, then plough the land a good depth to lie and take the changes of weather—frost and rain during winter. The soils best adapted for potato culture are sand, sandy loam, or hazel loam on gravel, and as we advocate the early sorts as being most profitable, these are almost the only soils which will be ready at the earliest period. Two ways of planting are advocated, and it must be decided which method shall be adopted at the time of ploughing before the winter, whether the plan of planting on the ridge or on the level. If the former the ground should be laid into ridges or stretches about 2 feet wide during the winter, otherwise the land may be ploughed and left during the winter months in the ordinary way. The question of manuring now arises; and when the land lies in ridges, if farmyard or town dung is used, the dung will be laid between the ridges split with a double mould-board plough, the sets of potatoes having been planted in the furrows with the dung. In the event of using artificial manures they may be sown broadcast; when the potatoes are set the ridges are split as before and the work accomplished. When the potatoes are to be planted on the level, and which is certainly the easiest plan, the sets are placed in every second or third furrow according to distance apart required. The planting is usually done by women, they doing the work best and most expeditiously, and a man with a seedlip full of manure following strewing the manure into the furrow upon the sets, damp ashes being mixed with the manure to prevent its being driven across the land by the wind, instead of falling directly into the furrow. We do not advocate the application of farmyard or town dung for several reasons. The first is, we have found that in the time occupied by laying-out and spreading the dung the land might be planted and finished-off if artificial manure only is used, because the work of ploughing and planting goes on simultaneously and without delay, and we have often noticed that whilst dung was being laid out the weather changed before the land could be planted, involving sometimes a loss of some days, or may be weeks, and this is a matter of immense importance in potato planting particularly of the early varieties. We also prefer artificial manures to dung of any kind; our own experience has proved that 4 cwt. per acre of Peruvian guano is quite equal to any amount or quantity of dung which can be applied, for we have frequently seen the best crop after guano, compared with a double dressing of rich dung. We have also noticed the result of experiments, the best results being obtained by the application of 4 cwt. of mineral superphosphate, 2 cwt. crude potash salts, and 2 cwt. of sulphate of ammonia per acre. In other cases nitrate of soda in conjunction with the mineral superphosphate has been very successful. One of the most important matters connected with potato culture in our own experience, is the fact that crops suffer less from disease when grown by the application of the hand-tillage manures than when produced by dung, and we have considered the cause to be that all dung opens the soil more than artificials, and allows the atmosphere to act upon the tubers, and this idea is supported by the fact that we have always found the soundest tubers were those at the bottom of the furrow or ridge, and farthest away from the atmospheric influence, and it also appears from the latest theory and experience of Mr. Smith, as related in the "Journal of the Royal Agricultural Society" in 1876, that the disease is produced by fungus, the germs or spores of which propagate the disease, and he recommends that all haulm should be destroyed by burning, but he says that the tubers may and often have the oospores attached to them, and although this theory is no doubt correct, yet there are certain conditions of the atmosphere most favourable to the spread of the disease. It is also known that it is very rare for oospores to propagate and produce the disease until after

a certain period of the year, varying no doubt, but seldom appearing before the middle of July. Thus it seems our best protection is to cultivate the early varieties which come fit to dig and sell, so that the land may be cleared before the end of July, the next crop also will then be got-in in good time. The later varieties of potatoes for use in the winter months are, however, a great essential to the consumers, and will have to be provided for on the home farm to a certain extent, and notwithstanding the liability of the late sorts to suffer from disease, there are certain methods to be adopted by which the disease may be avoided or diminished. 1st, The land to be planted should not have borne a potato crop the previous year; 2nd, That artificial manures are safer to use than any ordinary dung; 3rd, That the selection of sorts is of the utmost consequence, that any newly-propagated sort is more likely to evade the disease, and this accords with Mr. Smith's theory; and 4th, That the change of seed should be obtained from a different soil and climate from that in which they are to be planted, and we have never been more successful than when we have obtained the seeds or sets from the northern counties, or Scotland; and lastly it is essential that all keeping varieties should be allowed to remain in the land undisturbed until quite ripe and matured.

We will suppose the cultivation for the late sorts to be the same as for the early, but in planting we prefer that the rows should be 30 inches apart and the sets in the rows rather wider apart than for the earlier kinds. As to the seed, whether whole or cut, we always find that the kidney-shaped should be whole tubers, as they have generally but few eyes. The other round or oblong sorts will generally succeed well if cut into sets; and it is a saving, because eighteen or twenty bushels cut will plant an acre of land, whereas if whole tubers are set, even if small tubers are used, it will take several bushels of seed extra. We have found that the best and most loamy soils suit the later sorts better than the light or sandy soils. In the treatment of the plants after they have left the ground horse-hoeing and hand-hoeing should be continued until the plants are strong enough to be hilled or earthed up; and we prefer that a single horse plough be used rather than the double mould-board plough, as the hills can be more effectually made up by the one-horse plough. We, however, wish to mention a practice of our own adopted in cultivating late potatoes. We have been very successful in growing a crop of turnips with the potatoes, and when this was intended we sowed over the ground 1½ lb. of turnip seed per acre of the Greystone variety, or any of the quick-growing sorts, just before hilling up, and in the act of hilling the potatoes the turnip seed was buried on the hills; and whenever the season has been moist and favourable we have grown as much as twenty-eight tons per acre of turnips, some of which were sold with the potatoes at a good price. Other portions were pulled and used for feeding fattening oxen and sheep. When grown in this way of course the turnips cannot be hoed or singled out in the usual way, but they throw up so much green that as soon as the potato leaf falls they effectually keep down the weeds, except a few tall sorts which we hand-pull. The small short-hauled sorts of potatoes are best adapted for this double cropping, particularly the original white-blossomed Fluke, which we were the first to introduce into our district and first obtained from Lancashire. Our practice being to sell the potatoes in the ground, the buyer to dig and remove the crop at a certain period, enabled us to take away our turnip crop in good season in the following manner: The women pulled and carried in their apron laps the turnips off the potatoes by clearing fourteen hills at a time; the potato-diggers followed, clearing the fourteen hills, and thus enabling the carts to enter and remove the turnips. In this way each crop was removed in good season. It will of course be noticed that this plan cannot be carried out with any variety of potatoes which make gross foliage. Another point is, we always found our potatoes much sounder under turnip double culture than when grown alone.

WORK ON THE HOME FARM.

Horse Labour.—Ploughing and the usual tillage for Lent corn will now be going on, and the strictest economy should be observed, seeing that horse labour is such an expensive item in farm management. When we have horses stout enough after any first ploughing, one horse is only required if the one-horse plough made for the purpose is used; but what is better still is the double furrow plough drawn by two horses, as it does extremely well where the land has been previously moved by tillage. Horses will also be engaged in rolling the meadow land previous to laying up for hay, this being the proper time for laying up, and before the ground gets too hard. After being rolled no cattle should be allowed to feed in meadows intended for hay crop; and this is now the proper time to apply artificial manures to meadow land. It should be done at once, in order that the manure may reach the roots of the grasses at the earliest period, and this is more especially required on dry soils, because, if the land is laid up early the grass will make an early start and keep the land moist if a dry season should succeed. The manure we recommend is 2 cwt. per acre of Peruvian guano, or 1½ cwt. nitrate of soda, with 8 cwt. superphosphate. If, however, the meadows show any moss

the ground should be harrowed before sowing the manure. This will weaken the growth of moss, and the manure will cause the grass to overpower it before the hay is cut. Should the pasture be bare of herbage sow in 8 lbs. of suckling per acre. If the trenching in the meadows has not been done it should be done off-hand and before rolling. We like narrow trenches best, about one-spade width. These do not tread-in so quickly with cattle as wider ones, because the cattle step over them instead of treading them in.

Hand Labour.—Some men may now be employed by screening chalk for the purpose of using with manure when turnips are drilled instead of ashes, particularly if land is not very fresh in chalk, and on some farms the chalking to the full or usual quantity per acre is expensive; for economy we therefore drill chalk about twenty or twenty-five bushels per acre. This effectually prevents club roots in the Turnips. Upon the majority of mixed soils, either gravel, sand, or clay, it is seldom applied in this way without direct benefit, as the plants are sure to make a more healthy growth. The screening when convenient may be done at the pit, otherwise in an outhouse or shed, as the chalk should be quite dry, and when it is at the homestead it will serve to employ the men of a wet day. Women should be employed picking stones, &c., off the meadows to be now laid up for hay. Both men and women may be now employed in planting cabbages if not previously done in the autumn. We rather like the spring planting best, because in case of hard frost or snow the larks, wood pigeons, &c., and sometimes ground game damage them very much. Those planted about March will come for use early and before anything else is fit for dairy cows of the root kind. We have seen also some very fine pieces of the thousand-headed cabbage. They give a large produce of food, which is much relished by cattle and pigs, and is very nutritious. It is the common practice to plant with the setting stick; but we have used the spade for planting for many years and much prefer it. When the men are used to the work they will do it very quickly; they use a light or half-worn spade, and introduce it at an angle of 45°, and when the earth is just lifted a woman following each man introduces the plant at the back of the spade, holding it in position until the spade is withdrawn. The man then puts his foot next the plant, which presses the ground firm on the plant. This enables the man to take another step and introduce the spade again. We have employed three men at a time on certain occasions, and they do the work as fast as they could take a steady step, the women being also accustomed to the work, and boys to bring the plants or extra women do it very nicely. In this way a great deal is planted in a day, and safer for the plants to take than when the setting-stick is used, at any rate if the weather is dry, for the dry top soil does not run in behind the spade as it does into a hole made by the setting stick; and if the ground is rather damp and kneads with the stick it does not prevent the proper planting with the spade; again, the advantage of spade over stick is that the roots of plants never need be doubled up, as they often are in hurried planting in the usual way. Spade planting, too, suits long-stemmed plants, particularly broccoli and thousand-headed cabbage, as they are usually long in the stems; and when the weather is ever so dry when planted at the back of the spade the roots go down at once into the bottom of the furrow, and have the advantage of the moisture, nor does the dry soil run in with the plant. We have grown Broccoli planted in this way by one ploughing after a cutting of trifolium. The heads cut in the following winter and early spring were very large, and proved to be a paying crop. The stumps, of course, were large also. These we always cut off at the rim formed by the fall of the first leaf; and we have weighed the stumps and had 14½ tons per acre. These were cut into lengths of 2 inches and passed through Gardener's turnip cutter, and mixed with meal they fed our fattening oxen as well as any swedes we ever used.

MANAGEMENT OF PASTURE AND PARK LAND.

THE writer of the article on page 95 cannot have had much if any knowledge of Cheshire in saying "Pastures resting on marl do not require bone or mineral superphosphate," and for which he gives reasons.

Probably nearly if not quite one-half of the land in Cheshire is more or less on a marl basis. I have lived in the county all my life, and in my recollection, when bone was scarcely known as a manure or too expensive for general use, large breadths of the Cheshire pasture lands were of that nature that it has been said of them "It would take an acre to keep a peewit"—cold thin-skinned clays, with "whipcord," rush, and pink grass predominating; but by the application of bone dust for a top-dressing, after drainage where necessary, such lands have been permanently increased in value 25 to 50 per cent. and more, the change being sometimes the greatest on the poorest land. The bones chiefly used formerly were raw and coarse-ground, and applied at the rate of about 20 cwt. to the acre. The effects have been visible in many instances for twenty years where the land has been kept in pasture. Bone, both boiled and raw, is still extensively used

on the pasture and mowing lands as well as in tillage, but generally applied finer-ground and in smaller quantity per acre.

On many farms within my recollection there was scarcely a field without a marl pit in it, marling being once an institution in Cheshire; but this has long been superseded by artificial manures and the increased cost of labour.—V.

THE PRICKLY COMFREY.—A correspondent informs us that he has three hundred sets of this, and he wishes to give them the best assistance with a view to obtain the greatest amount of produce. The land is not rich, and he proposes placing dung on the surface and raking it off when the plants commence growing. He asks if those who have had experience in growing Comfrey will oblige by communicating it to the Journal.

PEAFOWLS.

YOUR correspondent "C." may like the following additional notes on the Peafowl. They are not quite hardy, some having been frozen to death in a severe winter whilst roosting on the trees of Brechin Castle, N.B., and also near Carlisle. Fifty years ago they bred wild like Pheasants at Ashley Park, Walton-on-Thames, and were a suitable ornament to that fine old Elizabethan domain. I have seen from twenty to forty there at one time. In spring the cocks would each appropriate a corner of one of the lawns, spreading his tail whilst the hens would walk in admiration round him for hours. The latter would later on keep out of sight and away from the cocks in the wildest part of the park for breeding, returning to the lawns towards autumn, where they roosted in some old cedar trees, each usually accompanied by three or four young ones. They were left entirely to themselves and found their own subsistence. Occasionally stray birds would come from the adjoining parks of Oatlands and Burwood. The cocks were constantly fighting with the Turkeys. The young birds were shot occasionally and found good eating. They were mostly of the purple-winged variety. The full plumage of the cocks did not come, I think, till the third year.

Some of the finest Scotch fir trees in England are in the same park, Herons came regularly every January and bred in them, going to a distance for their food.—J. F.

ARE SHOWS ESSENTIAL TO THE PATRONAGE OF FANCY PIGEONS?

THIS is the question I stated that I should endeavour to answer in the negative. Grant the benefit which exhibitions have done the fancy, yet that fancy existed and prospered, though on a smaller scale, as we know, quite a hundred years before shows were heard of. If, then, shows ceased the culture of Pigeons would not cease. First, there have always been a certain proportion of the very best fanciers who would never show at all. They either loved their birds too much to like to part with them or to see their plumage spoiled—that beautiful bloom, so plum-like (on the Carrier especially), rubbed off, as rubbed off it is by railway journeys and hot Birmingham and Birmingham-like places of exhibition. If you want to see the difference and gain to the birds by non-showing, see these just once a-year, and once a-year only, taken from their lofts and shown at the Peristeron annual Show at the Crystal Palace. How different their look to the faded soiled appearance of those sent in succession to all the great shows of England! It is the plum without the loss of bloom, and the plum packed and sent in hampers to a distant market, to borrow an illustration not unsuited to the columns of a journal of horticulture. If shows have to be more or less given up for the commercial reason of their not paying, still I hold that Pigeons need not be given up. There is also too great a love of prizes, and in some a love of prizes rather than a love of the beautiful birds. Prizewinning is one of the weaknesses of the day. The man runs just as well whether he receive a prize or not, so of the athlete, &c. In former days none kept Pigeons, or rather continued to keep Pigeons, who were not genuine fanciers of the beautiful birds. There were two classes of fanciers—those by far the higher, as to the quality of their birds, who belonged to a Pigeon club. There were and are still among the *élite* of the fancy men of great discernment as to pedigrees and quality, deeply skilled, too, in the mysteries of matching and pairing and feather-breeding. What great practical knowledge such now have, and what very high-class enjoyment their hobby yields them—never, indeed, reaching perfection, but labouring on, trying to get further and further to and nearer and nearer on the road to absolute success. These are the fanciers; these are they who enjoy of all things fancier-talk, and as a consequence the society of brother fanciers. There being now better birds in England than ever, and easier communication between place and place, these high-class fanciers have the advantages of seeing each other and each other's birds easier than in former years. If a hundred years ago a Pigeon club could exist and flourish, though limited very much to London fanciers, much more should one exist and

flourish now, or rather many of them, and these do not owe their life to the generally received Pigeon shows. That London will be the head of the English fancy is natural and suitable. Then there are our Scotch friends, to whom in regard to the revised and improved Pouter so much praise is due. Glasgow, I suppose, will be the head quarters of the Scotch fancy.

Coming back to England, there is much to be said in the probable extension of the high-class fancy from the greater numbers of London people who now reside a few miles from the great city. Not now are Pigeons kept so often in a London attic as in the last century and the earlier part of this, but in the wired-in loft at the bottom of a villa garden, or, better still, flanking a sitting-room, and the pretty birds visible and watched from the windows.

But there is another class of fancier who is still less dependant upon shows, I mean the man who keeps Pigeons for amusement only, often as ornaments to his place as others keep Gold and Silver Pheasants. These fanciers have always been numerous, and have perhaps got as much pleasure out of their birds as any of the highest fanciers. Nothing looks prettier than a country place with, instead of common birds, good fancy Pigeons flying about, taking their winged circles, strutting, walking, flying, appearing now at this part of a domain, now at another, coming for their morning meal or for their crumbs from the children's loving hands. These fanciers usually keep several varieties; not cultivating any one so very highly they can better do this, and as a reward for their catholic taste having great pleasure from watching the habits of the different varieties of birds brought under their eyes. I have observed that such general fanciers have now far better birds than formerly, when any bird with a larger crop passed for a Pouter, or with a longer beak and heavy wattle passed for a Carrier. Here we have an indirect result of shows, for the selling class has supplied such fanciers full often.

Thus I have endeavoured to prove the point which I undertook; at the same time I say, Have shows where possible.—WILTSHIRE RECTOR.

CRYSTAL PALACE BIRD SHOW.

THIS Bird Exhibition opened on the 28rd February and closed on the 1st inst. Undoubtedly it may be said to be *the* show of the year as regards cage birds, comprising as it did all the known varieties of the Canary tribe and British and foreign specimens. The number of entries fell short of last year, which did not surprise us considering that a show took place a few days previously at the Alexandra Palace. However, there were the goodly number of 1327 entries, made up with fifty-six classes of Canaries and Mules, the remaining forty classes having been devoted to the British and foreign birds. The high-coloured Canaries presented their usual warm appearance as regards colour, but we were sorry to find that, even with the high colour brought about with the cayenne food, some specimens in Class I were proved to be artificially coloured far beyond the effect produced with the stimulating condiment. The birds were excluded from competition, and not only those spurious-coloured birds in the Clear Yellow class, but all specimens entered by the same exhibitor, hailing from the salubrious town of Brighton. With this exceptional drawback the Canaries and Mules were fully equal to past shows. We noticed that the full complement of six classes were formed for non-peppered birds, and there was an increase in the numbers exhibited, notwithstanding that the Show fell short in entries generally. The British birds were in full force, and some lovely specimens of the Bullfinch, Goldfinch, Chaffinch, Linnet, Redpole, and Siskin, and many others were shown. In the two former classes alone there were over two hundred exhibits. The migratory and foreign birds were generally in good plumage, and their varied colours and talkative habits most attractive. The Show was well conducted under the guidance of the Deputy Manager (F. Savage, Esq.), who had a very efficient staff of officers at his command to carry out their respective duties.—G. J. BARNESBY.

RABBITS: HOW TO IMPROVE THE LARGER SPECIES.

LOP-EARED RABBITS have grown and improved with a rapidity that is sometimes surprising. The length of ear attained now is 6 or more inches greater than it was a few years since, and corresponding improvements have been made in size and colour. It is very important that steps should be taken to improve the foreign varieties, since they are very likely to degenerate. A few suggestions as to how to improve the breeds, chiefly in their propagation, may be useful. It is necessary to subdivide the remarks, because the same fancy that demands a large Belgian Hare also asks for a small Dutch, and the directions that would improve the former would spoil the latter. The benefit in the latter variety is supposed to be that when small the colour shows itself to much greater advantage. This may be so, but the slight benefit derived is much less than the harm caused by the loss of size, strength, and

constitution. Of course many general rules apply equally to foreign varieties as to Lops, but there may be some little matters specially to be attended to. Carefully see that both of the proposed parents are constitutionally strong, and let them be of good development, as already recommended. Avoid blood relation in any case, especially in breeds that are all of one colour, as these are apt to deteriorate very much by the process of in-and-in breeding, the colour losing its desired shade and becoming often streaky and pale; also be careful not to tax either parent too much, and let the doe's hutch be made in the manner already recommended.

In the *Patagonian* size is of great importance, therefore let both parents be healthy and large, though not very fat, the mother being large and strong. Some difficulty may be found in getting them to breed, and they should be carefully watched and paired in the first heat if they are not too young. Allowed to go off they sometimes fail to return for a considerable time. Good feeding during the time the young mother carries her young should also be a point, and of course doubly so when suckling. The breed are uniform in colour, which should be preserved dark, and consequently discretion cannot be thrown away in crossing the different shades. The ears sometimes droop too much. As this is because they are a little long pair them with short-eared varieties, and the defect in each case will cure the other. The shade should be as perfect as possible in both parents, light being paired with dark. Avoid, if possible, crossing with an animal of this variety that is at all spotted, as it is generally a sign of weakness that very frequently re-appears in the young. Size and strength must be great features, while colour and shade should not be neglected. A large hutch to enable the mother to have plenty of exercise is necessary for the proper muscular development of this variety.

Size is also a feature in the *Belgian Hare*, which should not average more than 2 or 3 lbs. less than the *Patagonian*. It is not, however, altogether so great a point as with the *Patagonian*, there being very many other points of great advantage in their improvement. Size must be carefully rendered as relating to the bony structure of the animal, and the whole idea should not be gathered from the weight. If weight is to be the guide any small one fatted up might be taken as a large Rabbit, which it would not be. The shade and ticking of each parent should be perfect, or nearly so. If either parent happens to lack any of the qualities necessary, if it has no tipping or too little, or if the shade be too light, it should be paired with one possessing all the necessary points, or, better still, should not be bred with at all. The shade should be bold and kept as near to the perfect standard as possible.

The *Silver-Grey* is different in many respects to either of the two preceding varieties. It is much smaller than the *Patagonian*, and a pound or two less than the *Belgian Hare*. Still it is in every sense a large and compact Rabbit, and large because the variable fancy does not object to size, and it is therefore cultivated. Shade is the great thing, and therefore Rabbits of the most approved shades should be selected, and of course they should be of the best breeds possible. Offspring of prizewinners should, where practicable, be used, as the shade will be more likely to be what is considered best. Several excellent stud bucks of this breed can now be employed at a very low fee, and advantage should always be taken of this opportunity to improve the stock and introduce fresh blood. Rabbits with white noses or very black heads should not be used for breeding, as these are bad qualities. Weakly specimens should never be used, as they are likely to have offspring with white patches on the skin, which detract from their value for furriers' purposes.

The *Angora* Rabbit, perhaps, is the most beautiful of the group of varieties under this head. Its points are very simple and plain and very easily improved in breeding. So many of the specimens are white that we may take them all so. The great features left will then be size and more particularly length of the wool. If the parents are healthy size may safely be left to take care of itself. Both of the parents should be over 6 lbs. in weight and not very fat. The most woolly couple that can be found should be used, and they should be either complete strangers or only very distantly related.—G.T.A.

VARIETIES.

THE organising Committee of the Poultry Club have elected the original members, some 125 in number, including most of the leading fanciers. We hear it was resolved that Mr. O. E. Cresswell of Early Wood, Bagshot, should be Treasurer *ad interim*, and collect all subscriptions for the current year by March 15th. He will then send to all full members voting papers for the election of officers and committeemen, which papers must be returned to him by April 1st. The list of the whole Club with its officers will then at once be published, subscriptions handed over to the Treasurers elected, and the responsibility of those who have organised it will be at an end.

— We hear that considerable changes will be found in the poultry schedule for the Bath and West of England Society's Show to be held at Oxford in June. The Society is very conservative, and has heretofore not adopted the modern system of

classes for single hens. This year, we believe, the exhibition of pairs of hens will be abandoned. We much regret this, for it is almost the last show of any eminence (save Oakham in the Dorking classes), where the pretty sight of well-matched pairs of hens can be still seen. The real origin of the single hen system was a desire to get more entries with the same entry fee for one hen as formerly for two. The reason always alleged in its favour has been the opportunity thereby given to small exhibitors who cannot match two hens. There is something in the argument, but when there are dozens of shows where single hens are shown (and the Bath and West of England Society must be far above all poultry attempts to gain a few additional entry fees) we sincerely wish that in this case pairs of hens might be continued.

— THE accounts of hatching thus far are much better than those of the last two springs. Eggs, however, have been scarce, and, though the winter has been so mild, we never before had so few in the months of January and February.

— THE increase of the Pigeon fancy has lately been alluded to in our columns; one sign of it is that several well-known poultry fanciers are becoming frequent exhibitors of Pigeons. Mr. T. C. Burnell, so famous for his Dorkings, was lately elected a member of the Peristeric Society, and his Turbits and Dragons have already made their mark.

— A TESTIMONIAL is being got up to Mr. Merck, so long Honorary Treasurer to the Peristeric Society. Subscriptions are received by Mr. G. South, 40, New Bond Street; Mr. Hedley of Redhill; Mr. P. H. Jones, of Raneleigh Cottage, Fulham; and by other members of the Society.

— WE regret to learn that legal proceedings are being taken against the Secretary of the last Bristol Show for non-payment of prizes.

— A CIRCULAR has lately been sent to us of a patent "egg preserver" sold by John Hargreaves & Co., 38, Union Street, Borough, S.E. It is a fluid for the "coating" of eggs for winter use. It is sold in 2s. bottles, and "stands" for the operation of coating cost 2s. each.—C.

— WE are requested by the Secretary of the Royal Commission to announce that the French authorities have extended the time for making entries to the horse show at the Paris Exhibition. Intending exhibitors should apply for forms, which must be filled up and returned not later than the 20th April next, to the Secretary to the Royal Commission, Canada Buildings, King Street, Westminster, S.W.

WINTERING BEES.

THIS subject is both interesting and important, and therefore ought to be well ventilated. The discussion of the subject will sharpen the attention and observation of bee-keepers in wintering bees in future years. When opinions are divided on questions of importance fair and friendly discussion helps to enlighten public opinion, which is the aim of all right-minded writers. The "RENFREWSHIRE BEE-KEEPER" says "Every bee tree in the backwoods of Canada is a standing proof that bees survive without the slightest artificial aid; if it does not bees would entirely disappear." I submit that no one can prove that every bee tree in Canada protects its inmates from injury by cold or damp. For aught we know, three-fourths of the swarms in the backwoods are killed every severe winter. If some strong swarms survive a severe winter they prove that bee-keeping is possible in the rigorous climate of a Canadian winter. I have met with but few records of wild bees or fugitive swarms in Canada or of honey harvests from them. Things are very different in warmer countries. In California, for instance, bees multiply fast and yield great harvests of honey. No one will, I think, question the fact that countries remarkable for their mild winters and warm summers are better for bees than are colder seasons. The cold and unfavourable seasons we have had of late years have nearly rid the northern counties of England of wasps and humble bees, but doubtless with a good season or two they will multiply again.

Your correspondent next refers to Quinby's system of inverting hives when placing them in their winter quarters—namely, thick-walled houses without windows. The hives were inverted with a view to let the breath of the bees pass off. We have always thought that Mr. Quinby's system of inverting hives in winter is a very foolish and harmful practice, for in this position the excrements of the bees could not drop out of but into their hives, and thus pollute the combs. But it should be borne in mind that the American bee houses are built and used to prevent the destruction of life by cold.

Our Renfrewshire friend next favours us with an extract from the writings of Mr. Langstroth. Writing on the 30th of January, 1857, Mr. L. says, "This month has been the coldest on record for more than fifty years. My hives have been exposed to a temperature of 80° below zero. . . . No. 1 was again examined and found in good condition. The central comb was almost filled with brood, sealed and nearly mature; all the combs were free from mould, and the interior of the hive was dry." Mr. L. adds, "Mr. E. T. Sturtevant of Ohio, so widely known as an experienced

apiarian, in a letter to me thus gives his experience in wintering in the open air. No extremity of cold that we ever have in this country will injure bees if their breath is allowed to pass off, so that they are dry. I never lost a stock that was dry and had plenty of honey. In the winter of 1855-6 I had twenty hives standing in a row. One of them was suspended 20 inches from the ground without bottom board, and with eight holes at the top all uncovered. All (nineteen hives) perished through the severity of the winter, while the open and exposed one came out strong and healthy." I am obliged by the reproduction of this evidence twenty years after it was given in America. At first sight it seems strong enough to convince the whole world. Has it done so? Has it been confirmed by the experience of American apiarians during the last twenty years? Some of my letters on bees are honoured by perusal and comment in America. Will some of the enlightened men there kindly notice this letter and tell us whether bee houses have been abandoned as worthless protection in cold weather, and whether the question has been settled or otherwise as to the harmlessness of extreme cold in winter to bees kept dry and well ventilated? Mr. Langstroth's statement of sealed brood in a healthy state in a temperature of 80° below zero is to me incredible—at least 40° beyond the range of probability. Would Capt. Nares and the men of the expedition that went to the icy regions to find the North Pole believe that bee brood could be fed and hatched in a temperature of 80° below zero? Dr. Cohan, one of the medical officers of the expedition, on his return to England fell into the arms of his brother and wept like a child in attempting to describe the awful human sufferings and deaths he witnessed in the cold regions.

I have seen brood in all stages killed outright by 12° of frost in hives partially covered and protected. Even in the summer weather of England, with 60° or 70° of heat, I have seen sealed brood perish when the bees of the hives could not cover it. This I have seen often. Bees are thoughtfully or instinctively concerned for the life and well-being of their brood during a change of weather from heat to cold. When hives are full of brood and the weather becomes cold, say in April and May, the bees try to keep the cold out by clustering in the doorway. This manifestation of care on the part of the bees is a proof that their brood is in danger, even in a temperature of 60° above zero. Here we may fairly notice the fact that young bees after they are fledged and hatched are often chilled to death in the colder days of English summers, say in an atmosphere of 60° of heat. Thousands are chilled to death by cold in their first attempts to gather honey. Who has not seen and pitied young bees perish on the flight boards of their hives, with pollen on their legs, unable to enter?

How it was that Mr. Sturtevant lost nineteen hives out of twenty is not clearly stated. His hive that survived the severe winter named had no bottom board, but was merely suspended and exposed in the air to allow the breath of the bees to pass off. Are we to believe that the nineteen hives were lost because they had bottom boards? If I understand the quotation aright this is what is meant. It is hard to believe that nineteen stocks out of twenty were lost owing to the use of bee boards. I shall be glad to learn that Mr. Sturtevant's statements have been confirmed by later experience, and that bee boards are better off than on hives in winter.

I will now leave the American evidence and give a little of my own experience. I do not remember losing more than one hive of my own from cold, but I have known many lost in England from cold when their combs and hives were free from moisture of every kind—as dry as it is possible to find them in any place. And what shall I say about moisture? No English writer on bees—no half-dozen of English writers, have said half so much as I have said against moisture and in favour of ventilation of hives, and the injury resultant if not ventilated. But the injury which I have seen from moisture inside and outside hives has been injury to combs, not directly to bees. Though I have seen hives wet enough both inside and outside, and the combs of such hives (outside the bee nest) perish and crumble into dust on being touched. I have never known a hive killed by moisture. When I kept wooden hives I found their insides streaming with moisture, which rotted the combs but did not kill their bees. I have seen hives that were driven from their stands by winds and winter storms picked up drenched and dripping with rain, replaced on their stands in this state, and come through winter. I have lost hives from foul brood, from hunger, from dysentery, from loss of queen, from scarcity of bees, one from suffocation on the way to the moors, one from winter cold; but looking back over fifty years I do not remember losing one from moisture.

Since I sat down to pen this letter a great naturalist has called on me. I have told him what I am writing about. He has not studied bees, but remembers being at Dudley in the winter of 1860, when the mercury fell to zero one night. A lady of his acquaintance there had just begun bee-keeping. Feeling the effects of severe frost on herself she took out four blankets and wrapped them round her bee hive. After the frost was gone her hive was found alive and all her neighbours' dead. Our friend's picture of cottagers' hives and their defective covering is rather over-coloured, but true in many instances. But the frost of 1860 swept

the bees out of many bee houses in England, which stood nearly empty for some time after.

I now leave this subject for a season, with the hope that many of our readers will carefully study it in all its bearings, for it covers a great many collateral points and practices of great importance in apiculture.—A. PETTIGREW.

FEEDING BEES.

I HAVE lately received several letters from readers of your Journal asking for advice as to the best manner of feeding bees at this time of year. Since I cannot reply to these separately I ask you to insert the following account of what I am doing with my bees at the present time. The genial weather has caused many spring flowers to bloom unusually early this year, and during the whole of February the bees have been airing themselves, excepting on two or three wet and cold days. This activity, together with the presence of a small amount of pollen collected, naturally has caused brood to appear in all hives.

I began feeding my bees on February 20th, a bright warm day, having previously ascertained that they all had a sufficient supply of honey still stored up to last them during the next two months. All floorboards were made clean, and any quilts which showed signs of dampness thoroughly aired. Home-made barleysugar is the food I give at this season. This cannot be carried down too fast, and is a constant and steady stimulant to the breeding powers of the queens. I have been particularly asked how I give the barleysugar. I make my quilts with a hole in the centre of each. During the winter a square pad is placed over this hole. Now the pad is lifted, a piece of barleysugar placed on the quilt or on a piece of wire net over the skeps. A small deal cover (four pieces of 2-inch board, thin deal wood nailed together like a box without top or bottom) is placed over the barleysugar, and the pad over the box. The cover of the hive is then readjusted, and all is left warm as before, at the same time equally well ventilated. I employed sections of supers with the glass end for this purpose, in order to see when the supply of barleysugar wanted replenishing. This did not answer. The moisture from the hive condensed on the glass lid, dropped on the sugar and caused it to run down between the bars. By the present arrangement it continues solid until the bees have carried off the last morsel. About 2 ozs. is sufficient to place over each hive at the time, and I find that when the weather permits the bees to attack it as at present this amount is required twice a-week.

Pea flour as artificial pollen I began giving at the same date. I place a frame light, leaning against a long box—against a wall would do, facing south. Under this I have two large skeps loosely filled with clean deal shavings, and with pea flour scattered on and among the shavings. Hundreds of bees are to be seen diving into this "meal bin" and at every hive you will see the white-coated workers entering to be well cleaned by their sisters. After a dive among the shavings they generally settle on the sides of the skep or on a blade of glass and pack away as much as they are able of the flour into their pollen baskets. Thus some are carrying down the sugar, some are bearing home the pea flour, and to some another division of labour is apportioned; this is the duty of carrying home water. Great quantities are now being required, and as breeding proceeds greater quantities will be needed. In a sheltered corner I place several large flat pans. Again I employ shavings, filling the pans with them and then pouring in water. The bees have foothold on the shavings and easily take in a supply of water. This assistance given to them is fully appreciated by them. Formerly they drew their water from a large butt, standing head downwards, on the sides within. Many were drowned. The pans are placed close to the butt, and this season I have seen two drowned bees in the butt; they must have been very young! I have not seen one drinking inside the butt.—P. H. PHILLIPS.

BAR-FRAMED HIVES AND THEIR MANAGEMENT.

No. 4.

AFTER seeing to the due arrangement of combs and the perfect cleanliness of his hives, the bar-framist sets himself carefully to watch his bees to see how far the early signs of promise are followed up by a visibly increasing prosperity. The early signs of promise are manifest in all hives which send forth pollen-gatherers on every favourable occasion of mild weather and warm sunshine. The more of these in any case and the more active and persevering the greater his satisfaction; but it does not follow (he knows too well) that this promise will in every case be fulfilled. Queens sometimes die in the early months of the year, in which case pollen-gathering gradually ceases. Here is a case requiring careful treatment. Should this manifest itself not earlier than April, or even the last week in March, all may yet go well. If the bees discover their loss in good time and set about rearing a queen there will surely be some drones developed in the neighbourhood sufficient for the young princesses. This should be ascertained by careful examination of the frames. If the loss of the old queen

took place earlier in the season, or if the bees are too few in numbers to give good hope of successful recovery, it will be found very profitable to break up the failing hive and to join the population to some other stock which may be most in need of such addition to its strength. This can be easily effected by taking out of the one hive some of the still empty combs, and replacing them by such brood combs as may happen to be found in the queenless stock, after previously sweeping the bees off them. This done, the queenless bees should be carefully collected in a small box and set over the centre hole of the stock to which they are to be joined after a sprinkling with sugared water. They will in due course find their way down. Another method of joining them is to collect the bees by driving and dash them out in front of the hive to which they are to be joined. A slight sprinkling with syrup as they are on the march will cause them to be well received. This addition to the population of the strengthened hive will make a great difference in its coming prosperity. As to the hive thus broken up, its bar frames can be cleaned out or re-adjusted, so as to be ready for the first swarm. It will be a material help to the new colony, and enable them to make such a start as will probably allow of one or more supers being taken off in excess of what the bees would otherwise have collected. Here, again, we cannot fail to observe the great advantage of the bar-frame system over the old skep fashion, in the ease and facility with which the mischief going on in any hive can be detected, examined, and remedied with the least possible disturbance and the greatest economy of material. Thus prepared, and with all his hives in the best possible working order, the bar-framist approaches the busy season, so full of interest and only too short, which is ushered in by the month of May and the swarming season.

The questions now anxiously debated in the mind of all bee-keepers are twofold. First, How to prevent swarming if the apiary is sufficiently large, and thereby to secure a proportionately larger harvest of honey. Secondly, To avoid, if possible, the escape of swarms, which oftentimes makes bee-keeping a grievously disappointing pursuit. Let us begin with the former, which, of course, will partly meet dilemma No. 2.

Now, to prevent swarming in every case absolutely is impossible without so crippling a stock as practically to make it useless for profit. But we can in most cases so manage our hives as to reduce swarming to a minimum, and this is managed on the bar-frame principle with a facility and assurance of success not possible under the old system. First of all, bees usually will not swarm till their dwelling has become too straitened, and consequently too inconveniently crowded for their comfortable activity. It is true that they will swarm even in places where they have almost unlimited room, but in these cases it will generally be found on inspection that the arrangements of their dwelling, as in old buildings, hollow trees, &c., have not been convenient; hence they have swarmed, or else there has been some natural cause at work in the interior economy of the hive, as, for instance, when the bees have been obliged to raise a queen, or the loss (from age or other cause) of their late mother queen. Usually, however, say in nine cases out of ten, a judicious increase of space will effectually prevent swarming.

Meanwhile I would observe that it is certainly not good policy absolutely to prevent swarming. On the whole it is much more conducive to the general success of bee-keeping to allow opportunities for the natural (or it may be artificially contrived) increase of bees by swarming. I fully endorse what has been written in these pages on this subject by Mr. Pettigrew and others, and I am inclined to believe that it is advisable to allow every stock to swarm once (but once only) in every season. A well-managed apiary, therefore, should be so ordered as to allow of this, by keeping for winter a smaller number of stocks than the full complement of summer time. This can be easily managed in the autumn by a prudent reduction of the weaker hives by unions or otherwise. Allowance, too, will always be made for casualties. Few winters pass without the loss of one or more stocks in almost every apiary, while not a few are so reduced in population by the arrival of spring as to do little more than recover themselves afterwards. A few first-rate stocks allowed to swarm once will, in the long run, be more profitable than a much larger number managed wholly on the non-swarming system. Still, no doubt, when the number of hives is complete in any given spring, and a large quantity of honey is an object, we should be ready to prevent our bees swarming, and make the whole population devote themselves to honey-gathering.—B. & W.

VENOMOUS STINGS.

A POUltICE of common salt (chloride of sodium) applied as early as possible to the part stung and kept damp is an excellent remedy for the stings of bees, wasps, &c. A carriage horse of my father's was stung with a wasp in the eye, and my mother applied the above, which gave such relief to the poor animal that ever after he would come to her call, and, although a most difficult horse for others to catch, would allow her to bridle him with quite an affectionate submission. I have frequently experienced the healing qualities of this poultice, and have never known it to be

tried without giving the most marked and immediate alleviation. This very simple and efficacious remedy is nearly always at hand; and if any of your readers try it beneficially it would be well if they would let the public know.—C. BARNES, *Stationer, Lichfield.*

OUR LETTER BOX.

INCUBATOR (M. A. W.).—We cannot give you any relative information. We know of none in use.

FIRE LIGHTING (Anne).—We have not the book you mention, but the following extract answers your inquiry:—"In order to lay a fire so that it is quite sure to burn, first take eight or ten sticks of dry wood, some paper, a handful of cinders, and a few small knobby bits of coal. Clear the grate thoroughly from dust and ash, then put a thin layer of cinders at the bottom of it. Tear the paper into pieces about the size of a dinner plate, and squeeze each piece into a ball. Lay these balls on the cinders, and pile the wood lightly in crossbars on the top, being careful to leave plenty of room between them for the air to pass through. Now lay a few more cinders and the pieces of coal upon the wood, apply a match to the fire, and in a very short time it will burn merrily. If time is a consideration, the paper may be simply placed upon the cinders; but this method is not so certain to be successful as is that of tearing and squeezing up the paper. The reason of this is, that according to the latter plan the paper burns more slowly and longer, and so the wood has a better chance to ignite. The cinders should be placed first, because if they are not the shavings and sticks might drop through the bars as soon as they began to burn; and more than this, when the paper is lighted the cinders get hot, and their heat helps the larger sticks and the coal to catch fire. Cleverness in lighting a fire is shown by the number of sticks used for the purpose. There are capable housekeepers who boast that they can light a fire with four sticks. Extravagant servants sometimes use a whole bundle. The proper allowance used to be one bundle for three fires; but since wood has grown dearer the bundles have been made smaller, and now it is one bundle for two fires."—(Cassell's Domestic Dictionary).

REMARKS.

27th.—Dark and thick in early morning; fair until 4 P.M., when rain commenced which lasted until 9 P.M.; brilliantly starlight at 11 P.M.

28th.—Fair but dull morning, rain in afternoon, windy evening.

1st.—Damp, warm, rainy, and rather windy all day. [evening.]

2nd.—Dry, warm, pleasant spring day with hot sun; partially cloudy in

3rd.—Bright fine day; hazy in evening, but very little cloud.

4th.—Dull morning, but bright sunny afternoon, very clear at night.

5th.—Cooler and more March-like, dust blowing in places, and altogether less genial.

Rather warmer than last week, and unduly so for the time of year.—G. J. SYMONS.

COVENT GARDEN MARKET.—MARCH 6.

BUSINESS is quiet with supplies short in the fruit market. Forced vegetables have a downward tendency; and outdoor produce, owing to the mild weather, is abundant, and is with difficulty cleared.

HINTS ON LANDSCAPE GARDENING.—No. 1.

THE term landscape gardening if taken in its most comprehensive sense embraces everything that is done to embellish the surroundings of our homes, and while it is usually understood to apply to the laying-out of extensive pleasure grounds, yet the making of the smallest garden undoubtedly comes within its scope; and it is my purpose in this and following communications to consider the treatment of certain portions of gardens large and small, to draw attention to faults that are common, and to suggest such remedies as appear best adapted to each case.

I wonder who makes the gardens and plants the front courts of suburban villas? Is it the local nurseryman who professes to do landscape gardening and groundwork? or must we attribute the surprising, often startling, effects to the humble efforts of the jobbing gardener? However this may be, it is an undoubted fact that the result is not often satisfactory, and yet there is really no reason why even a small court may not be made ornamental. The reason why failures are the rule rather than the exception is because each garden is not treated according to its peculiar requirements; the style being usually too ambitious, florid ornamentation prevailing where only simplicity should be found; a multitude of plants occupying the space suitable for only two or three; trees filling the place of shrubs, and shrubs occupying the places of plants; a superabundance of vases; an elaborate geometrical design, affording just so many unmeaning patches of colour where either a single plain circle or no beds at all would be better.

How to suggest or apply a remedy for such defects is the difficulty, the treatment of most small gardens being more often a matter of fancy than of taste, to which the good folks who own them very likely lay no claim and are content to obtain amusement in their own fashion; and if they do find pleasure in the contemplation of a startling combination of scarlet and yellow, a row of huge *tazzas* reared aloft on pedestals, or a miniature Mont Blanc in the centre of their lawn, why should we try to mar their enjoyment of what they consider to be the very embodiment of perfection by vain hints of refinement, tone, repose? Rather should we strive to assist those whose efforts show that they have ideas of taste—one striving to improve, and will therefore welcome our counsel and turn it to account. The force of example is well known—establish one well-arranged garden, and depend upon it there will be a gradual improvement in all other gardens in its vicinity, and therefore we may reasonably hope by our teaching to improve many gardens indirectly.

Let us first turn our attention to the courts which we see in front of suburban houses, and what do we find? Sometimes a row of Planes, Limes, Sycamores or Poplars along the front, pollarded and presenting such a formal scrubby appearance that one wonders how anyone can be content to retain them in front of their windows. No doubt anything like a tree is grateful to the sight, and when such a leafy

screen is attempted—leafy, by-the-by, only in summer—I would suggest Mountain Ash, Snowy Mespilus, or Sumach as being from their moderate growth and ornamental appearance desirable substitutes for trees of loftier growth which must be hacked into pollards to keep them within bounds, and I know that all three of them answer in the soot-laden atmosphere of a London suburb.

Worse even than the pollards is a tree towering aloft near the windows, darkening the rooms, overpowering everything near them, and appearing altogether out of place. Not long ago I saw a *Cupressus macrocarpa* upwards of 30 feet high in such a position, and was amused at the owner's dilemma. What should he do? sacrifice the tree of which he was so proud for the sake of light and air, or live in perpetual gloom? Great as is the mistake in planting lofty-growing Conifers in such unsuitable positions one cannot feel surprised at it, for many of them are so elegant in their young state as to induce forgetfulness of the future. There are a few comparatively dwarf kinds making handsome specimens, and which are not likely to become too large. *Arthrotaxis selaginoides*, *Saxe-Gothæa conspicua*, *Thuopsis dolabrata*, *Thuja aurea*, *Sciadopytys verticillata*, *Retinospora leptoclada*, *R. ericoides*, and others. But I do not recommend Conifers for the suburbs of large towns, for they never answer well in the smoke, and can hardly be termed ornamental when stunted in growth and begrimed with soot.

Why is it that Holly is not more frequently used for roadside screens? The pollards to which I have alluded are of course planted to afford a certain degree of privacy, which they do very imperfectly. Now the Holly makes an impenetrable evergreen screen, not at all heavy-looking, but always ornamental; nor need it be at all formal-looking if a wavy serpentine outline is given to the inner side facing the house with either an inner row of *Rhododendrons*, or, better still, two or three semicircular clumps of *Rhododendrons* springing out from the Holly. Of other shrubs which answer well in smoky districts I can recommend *Ligustrum japonicum*, the Japanese Privet, with large handsome foliage and bold spikes of white flowers. I should think the *Escalonia* having such stout foliage and being so robust would also answer well, but I have not seen them tried. *Garrya elliptica* makes fine specimens in the London suburbs, and is precisely the sort of shrub for a small garden, as also is *Cotoneaster Simondsii*.

With regard to the internal arrangements of a front court, who shall venture to decide but the owner thereof? I at any rate hope to do most good by confining myself to general hints; and to my readers who like alpine or rock plants I will say, Do not pile up a heap of rocks upon your little lawn in front of your windows, but make one, two, or three low rock beds in the nooks by the Holly hedge and there plant your charming little miniatures, which are so beautiful that one cannot wonder at your liking for them. By rock beds I mean beds of soil with pieces of rock thrust in among the soil and so disposed as to form numerous cosy little nooks and corners. It was only a few days ago that, happening to be in the neighbourhood of Blackheath, I saw precisely the sort of rocky pile to which I object.

It was piled up out on the centre of a little lawn more in the form of a pillar than a mound, rock plants planted upon it, and with a Pampas Grass a-top of all. The remedy was as obvious as the fault. The rocks and plants should be arranged in a low bed in any corner or less conspicuous position, and the Pampas Grass put upon the turf in place of the rocks. Avoid many vases. If you have steps a vase upon a pedestal on each side of the bottom step, and perhaps another pair of vases in a similar position at the top step, may look well, but do not use more vases at the foot of or near the pedestals.

If you have walls plant Honeysuckles; there is one called *Lonicera flexuosa* that is very sweet and grows fast. It may also be trained up the stems and branches of trees. You should also have white and yellow Jasmines upon your wall, a purple Clematis (*C. Jackmani*) to give summer flowers, with the white-flowered Clematis montana for spring, and the French Clematis Flammula with its sweet-scented pale yellow flowers for autumn. Then if you can contrive a flower bed or border do not fill it with scarlet Geraniums, but have a few Snowdrops, Crocuses, and Tulips for spring, and for summer sow some Mignonette, Sweet Peas, and Stocks, with a few Asters and Zinnias, and more Mignonette for autumn. If you have a little bed or patch of border near your sitting-room window sow it with the Night-scented Stock (*Mathiola bicornis*), and in summer evenings you will have a delicate but delicious perfume stealing into your room. Do not indulge in extremes, making your little garden a shrubby wilderness—the term is perfectly applicable to many a front court—nor cut it up into a maze of flower beds; a few shrubs and flowers such as I have indicated well tended and especially well watered will afford you much more pleasure than a crowd of plants, which, however choice they may be, have no chance of growing either into beauty or health.—EDWARD LUCKHURST.

JUDGING ROSES.

[Read on March 5th, 1878, before the General Committee of the National Rose Society.]

1. *What is a Good Rose?*—A first-class Rose must have form, colour, and size. I believe that the majority would arrange these points in the above order. For my part I think that all three are indispensable. If a Rose has ugly shape, faded colour, or inferior size, it is not up to the mark, and must be reckoned a bad bloom. As to form, I am content with Canon Hole's definition, "Petals abundant and of good substance, regularly and gracefully disposed within a circular symmetrical outline" (p. 207, ed. 2). As to colour, I mean the deepest and most brilliant tint which is known by the practised eye to be reached by each variety. I am a strong advocate for colour, and would at once eliminate a dirty or faded bloom, even though it possessed form and size. As to size, the average size in a box of show blooms should be large, but I think that the capabilities of each separate variety should be fairly taken into consideration. No account whatever should, in my opinion, be taken of the soil where the Roses are grown or the distance which they have travelled.

2. *Staging.*—A superior style of staging shows off a bloom to the best advantage, and thus influences the eye of the judge. But, as a matter of fact, almost every exhibitor of any pretensions does in these days of close competition stage well. Should two collections be deemed exactly equal, I would leave it to the discretion of the judges to decide whether the difference in the style of staging be sufficient to justify them in separating the collections.

3. *Points to be given to Teas.*—This is, I think, an open and difficult question, on which good judges differ. On the whole I think that Teas can afford to stand on their merits, no extra allowance being made for the fact of their being Teas. Good Teas are splendid flowers, and will hold their own against the Hybrid Perpetuals. In size they do not average as large as the Hybrid Perpetuals; but in delicacy of colour they are superior, and they are decidedly better travellers.

4. *Selection and Number of Judges.*—With all deference I submit that no one should act as judge who is not a successful exhibitor at first-class shows or has quite lately been so. I think, too, that he should have been successful in the larger classes. To one who is so I leave the judgment of my blooms with quiet confidence, but anyone who is not I thoroughly mistrust. I have never suffered from bad judging at a London show, but twice last year at country shows I was beaten, not by the competitors, but by the judge. I made no complaint, but I do think that secretaries of country shows should take

more pains beforehand to secure judges in whom confidence will be felt. It is quite common to find local men of no status in the Rose world acting as judges at country shows, really competent growers being present and not asked to do so. As to number of judges I would have three if possible, if not, one. Two is a bad number, for if they differ the reference to some third person not being a responsible judge is very unsatisfactory.

5. *Method of Judging.*—I agree in the main with the usual system mentioned by Mr. Camm in the *Journal of Horticulture* for Feb. 7th:—viz., Given three judges and the collections which have no chance being eliminated, each judge takes it in turn to count, the other two judges stand behind him and stop him when they do not agree. If there is a difference of opinion the majority at once decides. There is no delay. Good blooms have to be counted, and bad blooms have to be counted. I should like to count in the following way:—Give one point for each good bloom, take off one for each bad bloom; do not count the average blooms at all. In addition, a very good bloom should have two, and one of those exceptionally magnificent blooms (of which there are perhaps two in the whole show) should have three marks. Two marks might be taken off for a very bad bloom; in prize boxes they hardly ever occur. Competent judges can go over boxes at a good pace by this plan, and there is nothing complicated. Boxes found to be equal in number of points should of course be placed side by side for accurate comparison, when the average size, form, or colour will probably be seen to differ sufficiently to separate them. If not, they must be placed equal. I think it would be a good plan to mark on the prize card the number of points given. Those who stand second or third in a class would then know by how much they were beaten, and it would be gratifying to those who were in the running, though not placed, to have their points written upon their exhibition cards. The time taken would be very short. Another advantage of marking the points is that it would show the opinion of the judges of the actual merit of the collection, independently of that particular show.

6. *Time of Judging.*—Let the judging begin at the time advertised. It is very unfair on those who have come long journeys to have their blooms kept waiting, as they not unfrequently are, until from one to two hours after the time advertised for the judging to commence.—T. H. GOULD, *Mortimer, Berks.*

I AGREE in the main with much that has been written by the Rev. Canon Hole, but object to the idea that size is the last consideration. Now I maintain that for a stand to have a chance it is absolutely necessary for the flowers to be large, but not coarse; form also must accompany them. I therefore put it that those two points are of equal consequence. I should then look for freshness and brightness. Flowers a day too old have more size, but have a *passed* appearance, and always ought to have a bad mark on that account. Variety in a collection I think of the highest importance, and for this reason I regard Teas and Noisettes in especial favour, as they brighten and relieve a stand very much, but I should never put one in because it is a Tea unless it were a good one. Evenness in size all through will commend itself, and so ought good foliage. The arrangement and setting-up always speak for themselves.—BENJAMIN R. CANT.

My friend Mr. Peach entirely mistakes my meaning when in his last interesting article he mentions that he disagrees with me when I think that "the names of judges should be published, under the idea that exhibitors should try to please the taste or fancy of the leading spirit among the judges." Now, I thoroughly deprecate entertaining this idea, and on a second glance it will clearly be seen, I think, that my words do not bear out that supposition. On the whole I am against open judging. Granting that the Rose judges, *par excellence*, are few, and leading exhibitors usually betray themselves by their writing or setting-up of the blooms, still Roses, I hold, will as a rule be more generally decided on their own merits (the great desideratum) by the present fashion of close judging, while to expect judges to be entirely free from involuntary bias would be to expect human nature to be perfect. I find myself to be in an absolute minority in objecting to the National Rose Society issuing a code of rules for the direction of Rose judges, still I am quite open to conviction. This much I already concede, that plain carefully drawn rules emanating from a central authority must be of the greatest benefit to judges, and indeed all managers of country shows; but my

'friend' Mr. Baker is oversanguine if he expects any written regulations to clear out, as with an enchanter's wand, that Pandemonium into which a Rose exhibition is converted for an indefinite chaotic period before being cleared for the judges to begin their rounds. Mr. Newman will, I am sure, add the weight of his experience to mine that despatch at that critical period entirely depends on the official in command.

I should like to endorse what I think has already been alluded to, I mean the harmony of apparently conflicting ideas among correspondents. Travelling over different roads at greater or less angles we seem in our own method to arrive at the same point. The idea of "H. C.," for instance, about counting by point cards I feel sure will do infinite good at more than one country show this year. To the tyro and unpractised in music what master would fail to counsel the most diligent use of counting as a regular habit? and even as the thorough artist feels himself obliged occasionally to have recourse to the practice to steady himself, so an efficient Rose judge may well avail himself of this orthodox method in an exceptional emergency, though tedious and useless as a rule. Again, as regards the disputed pre-eminence of the different qualities in a Rose, I hold size to be the main point, though here we have the same standard of excellence in view, because with this qualification all others in a perfect bloom (which of course is meant) are included, whereas you may have shape, freshness, form, &c., *ad infinitum*, without size.

The question of size goes far to settle the debated point of the admissibility of Teas into which "M. N. R. S." calls the mixed system of Roses, also as to whether Teas are to be handicapped favourably. I am sorry I cannot agree on this latter point with my friend "WYLD SAVAGE," much as I should like to do so. Teas I hold, however, if of sufficient size, like good wine need no bush. Their delicate, slender, maidenly figures must ever stand out in charming contrast with the more matured matronly embonpoint of the H.P.'s, not to forget the exquisitely blended tints of white and pink which light up so effectively the dull surface of the reds and darks, especially at early shows, in the exhibition box. Mr. Cant (who I wish would give us his views), I feel sure, will fully endorse my views, seeing he would go the length of giving extra marks for well-grouped exhibits.

In addition to the prize of £3 3s. for eighteen triplets of Teas and Noisettes offered for competition by the Editors of our Rose Journal at the next National Rose Show, I am happy to state Mr. John Arkwright of Hampton Court, the winner of all the Maréchal Niel prizes last year, has kindly given a cup and £5 for an amalgamated box of twelve Teas and Noisettes and twelve H.P.'s, to be competed for at the West of England Rose Show at Hereford next July 3. I venture to predict that the result of the competition for these prizes will go far to show that the lovely Tea Roses can hold their own either by themselves or in any company, and that on their own merits without favouritism.—THE HEREFORDSHIRE INCUMBENT.

I PLACE the points as follows:—1st, Form and symmetry; 2nd, Colour, freshness; 3rd, Size; 4th, Substance of petal; 5th, Foliage. I do not consider that a Tea Rose ought to carry an extra point, as some of our most beautiful hybrids are equally as difficult to show; for instance, Marquise de Mortemart, Lord Macaulay, &c. A box of Roses ought always to be as near uniform in size as possible; therefore evenness of arrangement and variety of colour are great desiderata.—A. SARGANT, *Reigate*.

KEEPING GRAPES.

WITH respect to the question whether Grapes grown entirely in inside borders keep any better than those having a run of outside borders, allow me to say that the only Grapes keeping well in all respects here this season are some Muscat of Alexandria bunches, which were part of the produce of Vines with roots entirely inside. The same Muscat, Royal Vineyard, Raisin de Calabre, Gros Guillaume, Mrs. Pince, and Lady Downe's from vineries with outside borders are one and all affected with a disease of the stalks and entire framework of the bunches, which is new to me. These have shrivelled in an extraordinary manner, whilst the berries have remained quite juicy though slightly shrivelled. The last of the Black Hamburgs went in exactly the same manner. I attribute this to the saturated state of the outside borders and their consequent coldness, aggravated by the rather high temperatures necessary

to have the Grapes ripe before winter. Two years ago I kept Muscat of Alexandria and Black Hamburgs from the first-mentioned house until March, these having been ripened in the earliest part of August. In very many localities where heavy rainfalls are the normal condition, and more especially where the natural drainage is bad, I would be inclined to vote for inside borders for late Grapes in preference to those partly inside and partly out. I may further say, in my last situation, with a particularly dry soil, I kept Lady Downe's and Mrs. Pince hanging in excellent condition on the Vines till the buds "broke." The border was wholly inside, and the Vines started into growth in April.—R. P. B.

NOTES FROM MY GARDEN IN 1877.—No. 2.

GLADIOLUS.

I HAVE now for many years, probably as long as any amateur in England, grown this beautiful autumn flower. I can look back and trace the marvellous improvement that has taken place in it; can remember when various contrivances were adopted to present spikes with a good face owing to their habit of being winged, and when half a dozen blooms on a truss were considered quite an achievement, and now see how different they are: but I may at the same time say that I have never (save once when nearly my whole collection was swept away) had so calamitous a season as the past one. I know there are some who say, "You ought not to mention these things; you will discourage the growth of the Gladiolus and spoil business." I should be sorry to do so, but after all truth must be spoken; and with respect to the Gladiolus, the truth is that of all the disappointments which a lover of flowers has to endure, there are none to exceed those of the amateur who grows this flower.

I said I can look back on many years of culture, but let me say my culture never exceeds a few hundreds of plants; and during those years I have seen amateurs, aye, and nurserymen too, one after the other, taking up the culture of the Gladiolus and dropping it owing to their losses; others say that named varieties are so precarious that they will henceforth confine themselves to seedlings, but these seedlings only preserve their character for a year or two and then fail. Various opinions have been given how to remedy these losses as to time and manner of planting, as to the character of the soil and the harvesting of the roots, but the conclusion of the whole matter is unsatisfactory.

As to my experience of last year, let me say that my collection came from various sources. I received from France the new varieties of the autumn of 1876 besides some other forms of preceding years, some new and some as old as Meyerbeer and Madame Furtado. I had also a few from my friend Mr. Banks's garden at Shobden, some of English-raised seedlings which had been let out at a high price, about half a dozen from my friend Mr. Galloway, and of course my own stock saved and harvested in good condition. I planted two large beds besides a smaller one, and a bed of seedlings and mixtures. These beds were of the ordinary garden soil and had been manured in the autumn. The ground was in capital heart when I planted them. Some, according to Mr. Galloway's advice, were planted 6 inches deep, others 4 and 5. Some of the larger bulbs were cut in two, the remainder planted whole; but wherever or however planted the result was the same—many never came up, and of those which came up and bloomed a great many died, so that I did not at the end of the season take up one-half of those I planted. I cannot believe it was any fault of cultivation, for some of the spikes were the finest I ever had; and it was not the fault of any one particular strain, as I obtained them, as will be seen, from various quarters.

And now what is the reason of this failure? A very distinguished grower who grows them by the acre laughs to scorn my statement that it is disease. I never meet him but he gives me a friendly thrust and says, "You ought to be ashamed of yourself of talking of disease: it is nothing but exhaustion. I am a practical man, have been amongst them for thirty years, and think I ought to know." Imagine the employer of a thousand men, who is told by a physician that there is an outbreak of fever amongst his men, that he has been from house to house and finds them low and fading away, and that the disease is gaining ground; and that to him the employer says, "Fear, fiddlesticks! Nothing but exhaustion. Sir, do you think I don't know? I have employed thousands of men, and think I ought to know something about them. I am a practical man, sir, and I say it is not fever but weakness."

The physician would probably smile, if he did not turn angry, at what he would call the ignorance of his friend. Now we have the statement on one side of practical men, who look only at things as they present themselves outwardly to them, who affirm that there is no disease; and on the other the statements of such men as Berkeley and Worthington Smith, who, having subjected the corms to microscopic examination, affirm that it is disease and that it is analogous to diseases affecting other bulbs, but who are powerless to suggest a remedy for it as our best physicians are for some of the diseases which affect the human frame. I would rather follow the investigator than the practical man who only looks at the surface of things.

With regard to the new varieties of last year, there were as usual about a dozen of Mons. Soubet's and some eighteen of Mr. Kelway's. Of the latter I can say nothing, as I have not seen them; and with regard to the French varieties I can only give the following notes, as a few did not bloom. I think the two best were *Carnation* and *Panorama*. *Carnation* had a very long spike, some fourteen flowers being out at the same time; the colour was French white, with the edges of the petals flamed and striped with deep carmine, with dark purple spots in the centre of the petals. *Panorama* is a lilac flower with bright carmine markings, centre white: a new shade of colour very difficult to describe. *Diamond*, which came out at a very high price, disappointed me much, and I do not think that there was anything very remarkable in the other flowers; but then, as I have said, the season was so bad that some never came up and others did not bloom.—D., *Deal*.

PREPARING STOCKS OF BEDDING PLANTS.

THE propagation of tender bedding plants will now be proceeding apace in all gardens where large quantities are required. To many whose appliances for propagating are far from being first-rate, the providing of a sufficient stock of good plants by the time the weather is sufficiently warm for filling the flower beds is very often a serious business. The most common source of annoyance seems to be a shabby stock of stove plants to commence with. During the winter the plants get into a dwindling state, and much time is lost in bringing them into a healthy growing condition. All autumn-struck stove plants ought to be planted thinly in the boxes they are to be wintered in, using a holding soil, and allowing them a temperature sufficiently warm and no warmer than just to make a stubby growth. Plants thus treated supply a stock of cuttings early in the season without any forcing to have them ready. We had from eight hundred to a thousand each of varieties of *Lobelia*, *Verbena*, *Ageratum*, *Iresine*, and *Königa*, as a first batch of cuttings this season. These are again at a stage to multiply themselves (without cuttings from the store plants) at the rate of one and a half cuttings to each.

I do not like a high temperature for these at this season, consequently as they become rooted they are draughted into houses having a temperature of about 50° as the minimum. When sufficiently strong the rooted cuttings of *Königa variegata* are planted in cold pits. In April matters are very much simplified in producing plants in any quantity. Cucumber and Melon frames, and also pits heated by means of fermenting material, have the surfaces entirely covered with soil and dibbled full of cuttings of all sorts of bedding plants, which readily strike in that manner. When well rooted they are boxed-off and transferred to vineries which in that month have all a quick-growing temperature.

Plants raised from seed are mostly provided with little trouble, as, for instance, *Perilla* is sown in boxes, and when the seedlings appear they are transferred to cooler quarters, in due time to be planted out in cold pits with *Königa*, *Verbenas*, &c. Stocks, *Asters*, *Tagetes*, *Phlox Drummondii*, and such-like are sown in cold pits in April thin enough to allow the plants to be left till required for planting-out.

It is of great importance to keep all plants intended for bedding-out in a growing state from the time they are rooted till they are planted in the beds. The above-mentioned conditions secure this so far, but in addition it is found to be very necessary to cultivate the plants highly. Thus the whole of the store pans are surfaced with Standen's manure early in the year, and are also kept watered with manure water. This tends to the production of strong cuttings. Then, instead of striking the cuttings in sand and water they are dibbled into a sound growth-producing compost, and when transplanted into other boxes or planted-out in pits a compost of as good

loam as can be had with a liberal addition of Mushroom dung added is used. In due time these are also treated to manure water, the growths are pinched when necessary, and in the end the results justify the means.

April-struck plants of *Ageratums*, *Verbenas*, and others of a like nature are as a rule as good or even better plants by bedding-out time as are those struck earlier in the year. It is necessary to plant *Lobelias*, *Ageratums*, *Verbenas*, *Violas*, and *Iresines* in very highly manured soil, also after planting a mulching of Mushroom-bed dung is of great value in causing these and kindred plants to grow and flower satisfactorily throughout the season.—R. P. BROTHERSTON, *Tynningham*.

THE ROYAL BOTANIC GARDENS, KEW.

SINCE the publication of our remarks on the opening of the Royal Botanic Garden at Kew to the general public as a recreation ground during the whole of every day we have had many communications, all agreeing with what we said on the subject. We publish to-day a letter received from "A COUNTRY GARDENER," which places the matter in its true light, and the same opinion has been expressed by others who are not residents in the country, but being students of science complain that they are restricted in the use of the garden for scientific purposes by non-admission before one o'clock.

There is much truth in the representations of both classes of correspondents, and we have often thought that some arrangement might be made by which properly qualified persons could have the use of the garden at all reasonable times for the legitimate purposes of their profession. We have ourselves often found it hard when we required to visit the Botanic Garden, either for the purposes of investigation or to show them to a foreign visitor, that we were obliged to contrive some way of occupying the early part of the day till admission could be gained to Kew at one o'clock; and especially in the short days the inconvenience was aggravated, for before one gained admission at one o'clock there was not time to do what was to be done before the gates closed. Speaking personally we have always found the greatest courtesy from the authorities, and every facility has been afforded when application has been made in special cases; but some people have a delicacy in making these applications, and infringing on what are supposed to be the rules of the establishment. We had long thought that some such rule as obtains in the case of the reading-room of the British Museum would work well, which is that botanists, students of science, professional gardeners, and others wishing to make a legitimate use of the gardens might be furnished with tickets, available and renewable for six months, to be issued by the Director upon application, certified by two householders that the applicant is a properly qualified person to receive the privilege.

Upon inquiry we find that there is some such arrangement as we have indicated, but it does not appear to be generally known, and consequently many who might obtain the privileges they so much desire are deprived of them through ignorance of their existence. We believe there is some such work as a Guide to Kew Gardens. If the privileges of scientific students and others were there stated, or if publicity were given to them in the horticultural and other scientific papers, the complaints that have been so long made would at once be obviated. Whatever is done we hope will be in the interests of science and of legitimate inquiry, and not to satisfy a popular clamour for what is neither requisite nor necessary, and what has nothing whatever to do with the Botanic Garden as a scientific institution, founded with the special object of advancing a special science.

It appears from your Journal (see page 167) that a local agitation is in progress for the purpose of having the above gardens opened to the public at ten in the morning instead of at one o'clock at noon. I am not surprised that you have spoken plainly against a change that would simply render the gardens a public recreation ground of the same nature as the parks attached to London and to other cities and towns. If the proposed change were granted where is the assurance that in time the "right of public meeting" would not be demanded? which would certainly be turning the gardens to a use for which they were never intended. While I consider it quite right that you should endeavour to sustain the integrity of Kew as a botanic garden, I still think that some change of the time of opening the garden to certain people and under certain circumstances is very desirable. Kew is regarded by

the gardeners of Britain as a great educational establishment, but to country gardeners residing long distances from the metropolis it is practically a closed book, because they have simply not time to visit the gardens and examine and investigate in any satisfactory manner without losing their night trains home. That, I submit, is not a sentimental but a real grievance. There is no place that I have visited with greater pleasure and greater pain than Kew—pleasure because of the means it affords of imparting valuable information, pain because due and sufficient time is not allowed for carrying out the object of a visit.

Like many other gardeners I have occasionally the privilege of spending a "day in London," and only a day. Kew is one of the places that I especially desire to visit, and I should feel it a great privilege if I could have entrance to the grounds and houses, solely with an educational object, at an earlier hour than one o'clock. I have more than once hung about Kew Green waiting for the opening of the gates, and have thus wasted valuable time, simply because it could not be utilised sufficiently near for me to have entered the gardens at the moment the gates were opened.

Kew is, I apprehend, a national establishment supported for a special object. With that object I as a gardener am particularly interested and specially identified, yet I cannot under the present rules derive any practical advantage which is supposed to be at my disposal by a visit to the gardens. When I visit Kew it is in the performance of a duty, which is very different to a jaunting pleasure excursion, and I submit that the means should be afforded me for the discharge of that duty. I do not think, therefore, that I suggest what is unreasonable nor anything that is contrary to the legitimate object of the establishment when I ask that the consideration of the authorities be given to the subject of admitting duly accredited and *bonâ fide* gardeners at an earlier hour than one o'clock. The numbers would be comparatively so few that no real inconvenience could arise from their presence to the working of the establishment, while the facilities thus accorded to those few would be really great and important advantages.

If the authorities should consider to grant such a privilege as is suggested it would of course be necessary to guard against its abuse. A ticket or certificate from any established London or provincial nurseryman might be recognised as sufficient vouchers to admit the bearer to the gardens. If these were to be granted only to *bonâ fide* gardeners or to such others as the authorities might determine there would be no danger of the system being abused. A gardener would only write to those who knew him personally or by business transactions for the requisite voucher, and thus there would be small chance for a visitor gaining admission by false pretences. I think if the privilege suggested were granted only very few would avail themselves of it, but the granting of it would nevertheless be warmly appreciated by the entire body of gardeners in Britain.—A COUNTRY GARDENER.

PARAFFIN STOVE VERSUS FLUES.

In answer to an inquiry on page 92 of the Journal, my experience, though very limited, yet being a very successful one, may be of use.

Having one of Rippingille's patent stoves with radiator (to burn paraffin), I had a stand made over it with zinc drawer for hot water, a bed of sand kept damp to put cuttings in or lay small pots on, a glazed lid which opens like the lid of a box, for the purpose of saving room. This propagating bed is placed in the sheltered end of a glazed pit. With the stove turned down at its lowest I have a temperature of 70°. I have had it at work since November striking Fuchsias and other things, and the seeds now sown in it are doing splendidly. By keeping a canvas cloth hooked round it or let down I can raise or lower the temperature of the house or the frame at pleasure.

I may say that I have lately tried a much simpler and less expensive arrangement of hotbed, in which a temperature of 65° to 75° is maintained, and in which I have started a number of tuberous Begonias most successfully. It consists in a box about 2 feet 6 inches square, with a bottom board of half-inch deal, on the outside of which is nailed zinc to prevent the wood burning. About 3 or 4 inches of sand kept very moist answers, I find, quite as well as the hot-water drawer; and there being only the thin board covered with zinc between the heat and the sand, it can be kept sufficiently warm by two very small paraffin lamps of that kind that have a bit of sponge in

them and are used without chimneys. A glazed lid or hand-glass can be used for cover. These two little beds are such a pleasure to myself, and one so easily made and managed, that perhaps the idea might help "E. H." or other amateurs who, like myself, love to see their flowers growing.—A. C.

THE MULTIPLYING OR TREE ONION.

I WAS very pleased with "A KITCHEN GARDENER'S" account of the cultivation of the Onion, and if all its growers follow his directions they may expect a good crop; but with his remarks about the Tree Onion I do not agree. I have been growing the Multiplying or Tree Onion for some years, and find it very useful and cultivated with much less trouble than the common Onion: it is also much harder. It requires the ground to be slightly manured. Then in February or March plant the bulbs in rows 8 inches apart and 8 inches apart in the rows. They require no further culture except to be kept well weeded.

They are very productive, one small bulb will grow into a good-sized Onion (and sometimes three or four like the Potato Onion); from that one is produced a stem about a foot high or more, and then a bunch of four or five more Onions about the size of nuts, the proper size for pickling, and then another stem and a bunch having still smaller bulbs for another year's planting.—J. BRACEBRIDGE, *Kilsby*.

SCOTTISH HORTICULTURAL ASSOCIATION.

THE annual general meeting of this Association was held at 5, St. Andrew Square, on the 5th inst., Mr. Dunn, Dalkeith Gardens, in the chair. There was a large attendance of members. Mr. John Methven, the Secretary, read the first annual report, which showed that since the institution of the Society on the 20th March, 1877, twelve meetings had been held, with an attendance of between eighty and a hundred at each. The number at present on the roll of the Association was stated to be 241. The Treasurer's report, submitted by Mr. Laird, showed that the total income had been £25 5s., the expenditure £14 18s. 11d., and the balance in hand at the disposal of the Society, £10 6s. 1d. It was stated that at the meeting of Council held on the 19th of February it was unanimously agreed to recommend the re-election of the office-bearers. The constitution and bye-laws of the Association were then submitted *seriatim*, and after some discussion approved of. The Chairman proposed that Sir William Gibson-Craig, Bart., of Riccarton, should be elected Hon. President for the ensuing year. It was agreed to increase the number of the Council from twelve to fifteen members, and the following were elected to fill the additions—Messrs. John Downie, James Grieve, and George McClure. It was announced that the first prize for a flower garden plan had been gained by Mr. William K. McLeod, Dalkeith Gardens; the second by William Martin, Linton Park; third by Wm. Garrett, Linton Park; fourth by Geo. McKinlay, Dalkeith Gardens. Sixteen plans were sent in for competition, all of them being of considerable merit. The Judges were Messrs. Webster, Gordon Castle; Thomson, Drumlanrig; McNab, Botanic Gardens; and Gorrie, Trinity. It was also intimated that Mr. Downie had again placed £5 at the disposal of the Association, to be applied as they thought proper.

A communication from the Royal Caledonian Horticultural Society was read in regard to adjudicating committees on new plants, fruits, flowers, and vegetables, which was remitted to the Council for the purpose of being carried into effect.

Messrs. Downie & Laird, Royal Coates Winter Gardens, exhibited to the Society a truss of a new seedling Himalayan Rhododendron. It has been named Princess Louise, and from its splendid colour and magnificent habit is expected to prove a great acquisition. The leaves are of a dark glossy green colour, and in form lanceolate ovate; the flower truss is dome-shaped, the pipe cup-shaped, of immense size and leathery texture; the colour cherry rose of a brilliant hue; the stamens black, and the anthers white, producing a novel effect. The flowers last for a great length of time owing to their great substance. The plant from which the truss was taken has over fifty flower heads fully expanded, and presents a noble appearance. Mr. Foreman, nurseryman, Dalkeith, exhibited a new seedling Skimmia; Mr. L. Dow, Langton Hall Gardens, showed the sweet-scented Iris persica in great beauty. It was intimated that Mr. McAdam, son of Dr. McAdam, would read a paper at the next meeting on the "Food of Plants." The meeting terminated with a vote of thanks to the Chairman.

PROTECTING FRUIT BLOSSOM.

EVERY year's experience proves that full crops of fruit cannot be secured on Peach, Nectarine, Apricot, and other trees trained on walls without shelter is afforded to the blos-

soms during the inclement weather of spring. Copings of various kinds, such as of glass, wood, and stone of various widths, are undoubtedly of considerable service, and in ordinarily mild seasons are generally sufficient to insure fair crops of fruit; but in such springs as those of last year something more is required to render the blossoms and embryo fruit safe. In addition to the copings protection is necessary to protect the blossoms from the cutting "ice winds," sleet, rain, and snow, which are too often prevalent during the blossoming period. For this purpose blinds of netting, tiffany, canvas, and frigi domo are employed; but those who have had recourse to those materials, while admitting their value, know that they possess certain disadvantages. Blinds that are sufficient to exclude frost for the same reason necessarily exclude light and a free circulation of air, which are essential to strong blossom and a good set of fruit; while materials that are suffi-

ciently thinly woven to admit enough of light and air are too often inadequate to exclude the frost. Thick blinds, therefore, have to be rolled up and down according to the changes of the weather, and when this is done carefully and intelligently good crops are generally insured. The real remedy is glass; for this, while it usually excludes such frosts as occur in spring, admits light, also air when due provision is made for ventilation. Glass coverings, although involving a little extra outlay in first cost, are in the end the most economical, because most permanent and effectual.

A plan of covering walls with glass projected by Messrs. Messenger & Co. of Loughborough, which appears to possess a combination of advantages, is shown in the accompanying engraving. The structure is light, easily fixed, readily removed, and ample ventilation is afforded. The lights when fixed slide on brass rollers, so that the trees can be syringed

Fig. 30.—MESSENGER'S WALL PROTECTION.

when necessary; and when protection is no longer needed by the trees the lights can be utilised for the growing of Cucumbers, Melons, and other tender crops.

Glass, however, while being the best of all protectors for fruit blossom cannot readily be obtained by all who possess fruit trees, and those should not neglect at this period of the year the covering of their trees with nets or thicker blinds, as may be the most convenient, for by these aids the prospects of a crop of fruit are considerably increased.

EUCHARIS AMAZONICA.

As to the merits of this grand plant in supplying a succession of flowers at all times of the year, and those of the first order, there can be no difference of opinion, and amongst stove-flowering plants there are few to equal it; therefore no collection of plants however select it may be is complete without the *Eucharis*, for whether it is grown for exhibition purposes or to supply cut flowers for epergnes, vases, or bridal bouquets it is alike valuable. There are few flowers that enjoy the same amount of popularity the *Eucharis* is justly entitled to, as witness the great quantity of blooms that are annually sold in Covent Garden Market. The length of time the flowers will last when cut and placed in water is another point that is highly in its favour, and provided the water be changed occasionally they will keep good and fresh for three weeks or a month.

In describing the cultural details I do not pretend to say that mine is the only mode of culture that produces good results, but I am prepared to say that it cannot be surpassed from the satisfactory way in which the plants under my charge here are constantly flowering. It is not unfrequently that we hear the charge of shyness in flowering preferred against the *Eucharis*, but those that do so have yet to master the details of its culture, for most assuredly under good management it is both a free-growing and most profusely flowering plant.

In order to make the cultural remarks as plain as possible

I will take the case of those who purchase a thrifty young plant well established in a 6 or 8-inch pot; this should be shifted into a pot two sizes larger, at the same time taking care to have the pots thoroughly drained. The soil I have found, after considerable experience, to be the most suitable for this plant is prepared by well mixing together two parts of a rather light turfy loam, one part of good fibrous peat, and a moderate proportion of well-decomposed cow manure, with a free admixture of silver or river sand. Some gardeners recommend burying the bulbs very deep in the soil, but I have found such practice to be erroneous; therefore I advise that the bulbs be buried just below the surface only.

Bottom heat is not absolutely necessary to the successful cultivation of the *Eucharis*, but it will be found highly beneficial in promoting a healthy and vigorous growth.

The plants must be shifted on as fast as they fill the pots with roots until they have grown to specimen size, or as large as they may be required; afterwards potting them once in two years will be quite sufficient. I am no advocate of a starving system, but I have found the *Eucharis* to flower more freely when somewhat confined at the roots than when over-potted. In shifting the plants into larger pots the soil should be used in a lumpy state, and some pieces of charcoal may be mixed with it. When in active growth the plants require an abundant supply of water at their roots, therefore care should be taken to drain the pots most effectually; and in potting into large pots leave a depth of 3 inches from the surface of the soil to the top of the pot, for in watering it will be found necessary to allow the plant to have a good soaking. When the plants are growing freely they will be greatly benefited by watering them twice a-week with liquid manure. The best I have yet used has been obtained by steeping sheep droppings or cow manure in soft water; it should be allowed to stand for a time until it has become clear.

The *Eucharis* delights in a temperature ranging from 65° to 80° with plenty of atmospheric moisture, which can be obtained by sprinkling the walks and every other available space during

bright sunny weather. If the plants are required to bloom at any specified time remove them to a cool house, give them only just sufficient water to prevent the foliage from flagging, and after resting them for five or six weeks remove them back to the stove and supply them plentifully with water again, and in three or four weeks the flower spikes will appear.

In taking charge of the gardens here in the spring of 1870 the plant that was mentioned by a correspondent of the Journal for February 28th was in a 9-inch pot, but in a very unhealthy condition. The plant was at once turned out of the pot, every bit of soil was shaken from the bulbs, which were washed with clean tepid water, and then potted and plunged in a bottom heat of from 70° to 80°.—W. JORDAN, *Gardener to J. Boustead, Esq., Wimbledon.*

[We have seen the plant that was referred to on page 166 as having produced upwards of five hundred flowers in a year; it is fully 6 feet in diameter, and is the finest specimen that has come under our notice. This will reply to "A SUBSCRIBER OF LONG STANDING."—EDS.]

A WINTER'S RAMBLE.

FOR some years I have made a ramble during a particular week in January, and always in the same locality, in order to note what plants were in bloom, as a record of the mildness or severity of the autumn and winter seasons, and for other reasons. Whilst in preceding years I have not found on an average more than twelve plants in flower in the district to which I limited my survey, this year I have recorded upwards of eighty British wild flowers, besides an unusually large number of garden flowers. The following is the list:—

<i>Caltha palustris</i>	<i>Geum urbanum</i>	<i>Veronica Buxbaumii</i>
<i>Helleborus foetidus</i>	<i>Alchemilla arvensis</i>	<i>Veronica agrestis</i>
<i>Capsella Bursa-pastoris</i>	<i>Spergularia arvensis</i>	<i>Teucrium Scorodonia</i>
<i>Draba verna</i>	<i>Sedum reflexum</i>	<i>Ballota nigra</i>
<i>Cardamine hirsuta</i>	<i>Cherophyllum temulen-</i>	<i>Lanum album</i>
<i>Barbarea vulgaris</i>	<i>tum</i>	<i>Lanum purpureum</i>
<i>Sisymbrium officinale</i>	<i>Federa Helix</i>	<i>Lanum amplexicaule</i>
<i>Cheiranthus Cheiri</i>	<i>Gallium aparine</i>	<i>Primula vulgaris</i>
<i>Sinapis arvensis</i>	<i>Sonchus oleraceus</i>	<i>Arneria maritima</i> (in
<i>Viola odorata</i>	<i>Crepis virens</i>	<i>gardens</i>)
<i>Viola tricolor</i>	<i>Leontodon Taraxacum</i>	<i>Plantago major</i>
<i>Lychnis vespertina</i>	<i>Lapsana communis</i>	<i>Plantago Coronopus</i>
<i>Sagina procumbens</i>	<i>Carduus nutans</i>	<i>Polygonum aviculare</i>
<i>Stellaria media</i>	<i>Senecio vulgaris</i>	<i>Euphorbia Peplus</i>
<i>Stellaria graminea</i>	<i>Bellis perennis</i>	<i>Euphorbia helioscopia</i>
<i>Arenaria trivernis</i>	<i>Chrysanthemum leucan-</i>	<i>Buxus sempervirens</i>
<i>Cerastium viscosum</i>	<i>themum</i>	<i>Urtica urens</i>
<i>Cerastium vulgatum</i>	<i>Matricaria Parthenium</i>	<i>Galanthus nivalis</i>
<i>Geranium sanguineum</i>	<i>Matricaria inodora</i>	<i>Luzula campestris</i>
<i>Geranium molle</i>	<i>Anthem. nobilis</i>	<i>Calluna vulgaris</i>
<i>Geranium Robertianum</i>	<i>Arbutus Uneio</i>	<i>Erica cinerea</i>
<i>Ulex europæus</i>	<i>Ilex aquifolium</i>	<i>Spergularia rubra</i>
<i>Ulex nanus</i>	<i>Myosotis collina</i>	<i>Daphne Mezereum</i>
<i>Viola hirsuta</i>	<i>Veronica hederifolia</i>	<i>Scieranthus annuus</i>

In addition to these I have found several species of Rubus, Rumex, Cyperaceæ, Juncaceæ, and Gramineæ. This list will, I daresay, cause surprise to some, and perhaps doubt; but in all cases except one or two the specimens I gathered were very good ones, and would not have disgraced any collector's herbarium. I have not included plants found in bud, though I have taken a note of them, nor those in fruit whose petals had evidently just fallen, but only those actually in blossom. I found them all within a few miles of Birmingham. I had not the opportunity to wander through Sutton Park, or doubtless some few others would have been added. Many of the localities where these plants were gathered are in exposed situations, and therefore one would have imagined it useless to look for them; and when we remember that in the Christmas week there had been several nights of sharp frost, and snow had fallen also, it is all the more surprising that so many different specimens should have been found. I am somewhat astonished that no list has appeared from the southern counties, which are so much warmer than our own midland counties; for, judging from a letter received from a friend in Devonshire, I should suppose that most of the summer flowers are still in bloom. He compares the Christmas week there to the Australian Christmas, and says that he gathered wild Strawberries (*Fragaria vesca*) in abundance on Christmas-day. He also mentions that two nests with eggs had been found—the one a thrush's, the other a hedge sparrow's. All these facts are certainly very interesting, and point to a most exceptionally mild winter.

Of the foregoing list some are plants that flower at this season of the year, and a mild winter only accelerates their flowering. Some few others may be seen in flower all the year through, but by far the greater number are, so far as the

experience of the last ten years allows me to speak, strangers to the late part of the autumn, and certainly to the winter. There are several absent that I have recorded in other years, such as *Ranunculus acris* and *R. sceleratus*, *Stellaria uliginosa*, *Erica tetralix*, *Lychnis diurna*, *Nepeta Glechoma*, *Senecio Jacobæa*, &c., and, strange to say, I did not find *Potentilla fragariastrum*, a very early little flower, neither did I find *Tussilago Farfara*. The mild weather still continues, and I notice that the Hazel and Willow are blossoming, and the Hawthorn leaves already appearing. Doubtless others of your correspondents can add a few more to the list I have given. I think the record would be worth the while, for careful observation may enable us in course of time to ascertain with something like accuracy in what manner and to what degree plants are affected by the weather. So far we notice that whilst certain plants live through the autumn into the winter under certain conditions of weather, others that appear much hardier do not; whilst, for example, *Ranunculus acris* or *Centaurea nigra* will be found sometimes in January after a severe and cold autumn, yet when the latter season has been mild and the winter also they are not to be found.—REV. JOHN CASWELL (in *The Midland Naturalist*).

OUR BORDER FLOWERS—KIDNEY VETCH.

THE Legumes are a very extensive race, but Our Lady's Finger, as called by some, though seldom seen under cultivation, possesses merits that claim our attention. *Anthyllis Vulneraria*, also known as Woundwort, under many circumstances proves to be an useful addition to our forage plants as well as beautifying our borders. In its native home in upland districts on the limestone it may be often found covering large spaces of ground, and when in bloom has an appearance that is not soon forgotten by the collector of native plants. There are variations of colour in our own Kidney Vetch, which by some are considered to represent permanent varieties. Their contrast of colours with their woolly and silvery-grey appearance adds to their beauty and interest. The plants are of somewhat trailing habit, and they appear to the best advantage when left to themselves. Our *Anthyllis* is more abundant on the limestone, where the flowers often change their colour from yellow to pink or rose, and in some instances to white; in less elevated and gravelly situations I have not met with the same variations of colour. They are useful plants for large rockeries and sandy slopes. The Mountain Kidney Vetch, *Anthyllis montana*, from the Alps, is one of the most interesting of the group, having dense heads of pretty pink flowers. Where there is any pretension to a collection of choice alpine plants this ought to have a very prominent place, on the rockery especially. The white variety is equally desirable, but is seldom seen. *Anthyllis*es enjoy a rocky medium, but they will thrive in ordinary garden soil mixed with grit or lime rubble. They are increased by seed, sown as soon as ripe or in the spring, in well-drained sandy soil kept moderately moist. When the seedlings are large enough to be handled prick them out in a sheltered situation, and subsequently plant them out where they are to remain permanently.—VERTAS.

CONOCLINIUM IANTHINUM.

ALTHOUGH admirably adapted for the decoration of conservatories and other structures during the early spring months, and for yielding cut flowers of the delicate blue of the *Ageratum*, the plant now figured is not so extensively cultivated as its merits deserve. The pleasing colour of its flowers associates well with other plants that are in beauty at the same time, and from all of which it is very dissimilar.

This *Conoclinium* is of easy propagation and cultivation. Propagation is readily effected by cuttings of the young shoots planted in the usual way, and kept in a moderate and close heat. The plants when established in separate pots of rich, light, loamy soil, should be frequently topped, and shifted into others of larger size before the roots become crowded in the pots; they should be kept near the glass in a house or frame where they can have a moist atmosphere with plenty of air, and a temperature of from 60° to 65°. Two-thirds of light free loam to one-third of good leaf soil or fibrous peat incorporated with sand enough to keep the mass open and porous, will form a compost suitable for the plants at any stage of their growth. By selecting established cuttings in spring, large plants may be grown by a continuance through the summer of the stopping and shifting processes; and such plants, from the free-flowering

habit of the species, are useful for late autumn and winter flowering in a warm conservatory. Young plants thus managed are preferable to older cut-down plants. But perhaps the most useful plants are those raised from cuttings struck later in the season and flowered in small pots, the plants not having been stopped, or only stopped once. Such plants produce fine

heads of flowers, and are very valuable for front rows in conservatories and for intermixing with other plants in the furnishing of vases. We have seen them effectively employed in vases in the conservatory at South Kensington, the plants being in quite a dwarf state, and having dense heads of *Ageratum*-like flowers.

Fig. 31.—CONOCLINIUM LANTHINUM.

During the winter an intermediate house affords a suitable temperature for the plants, and in summer they thrive well in frames in which a genial temperature is maintained by moisture and judicious ventilation. The plants may also be planted out in a sheltered situation during the summer, and be potted on the approach of cool weather in autumn.

Conoclinium lanthinum is a native of St. Catherine's in Brazil, from whence it was introduced by Mr. Voss to the collection of the late Mr. Verschaffelt at Ghent. It first flowered

in England in 1850 in the nurseries of Messrs. Rollisson of Tooting, and Messrs. Henderson of St. John's Wood. It is both distinct and attractive, and should be cultivated wherever a supply of spring-flowering plants is required.

THE ELECTRIC AUTOMATIC VENTILATOR.

THE model of this ingenious contrivance which was exhibited by Mr. Symonds at South Kensington on the 5th inst. merits

a fuller notice than could be given to it in our report of the meeting. We have since had an opportunity of more carefully inspecting the model, and can testify to its certainty of action. In its present form there can be no doubt that a hall or building not exposed to the sun may be ventilated by this novel contrivance in a satisfactory and practical manner. Presuming that a temperature of 60° is required the ventilator will open when the heat side of the electric thermometer reaches that figure on the scale, and the moment the mercury falls to 58° on the cold side of the scale the ventilator closes. In each case, both when open and closed, the ventilator is locked, and cannot be influenced by any other means than a variation of temperature. If the temperature increases to 60° and falls again to 58° fifty times in an hour the ventilator is as certain to act as the temperature is to vary above or below those or any other figures required, and to which the electric wire may be set.

Useful as that achievement may be for regulating the tem-

perature of a public hall or private room it is manifestly not sufficient for the ventilation of garden structures exposed to the action of the sun, and where the heat is required to increase and decrease gradually between a long range of figures as indicated by the thermometer. The inventor not being a horticulturist had necessarily conducted his experiments under a disadvantage so far as regards the ventilation of garden structures, and he was glad to receive a standard of requirements so that he might endeavour to render his invention really serviceable in gardening practice. We therefore suggested to Mr. Symonds that unless he could ensure a portion of the ventilators of a house to open at 50°, a further portion at 55°, and again at 60°, 65°, 70°, 75°, 80°, 85°, and 90° as the heat increased, and to close them again in a reverse graduated ratio of temperature or at any heat required, that his invention could be of little if any real value in gardening practice. He assures us that he shall have no difficulty in attaining the standard

Fig. 32.—SYMONDS' ELECTRIC AUTOMATIC VENTILATOR.

suggested, and that he will be prepared to exhibit a model which shall carry out all the conditions named.

The following references to the engraving will enable the working of the system to be understood. Only a portion of the moveable ventilating slides are shown :—

A, The frame. D, Slips of glass turning on points N. When the ventilator is open these slips are at right angles. C, Slips of glass or wood fixed at right angles to keep slips D at an angle of about 45° when shut. In the drawing the ventilator is represented as closed. The slips D are connected with the electric apparatus by means of upright rods E; plates or metal, X; pivots, G; and the connecting rod F, which passes through the hole H into the box containing the electro magnets, &c.

The ventilator is connected by means of wires to a constant galvanic battery, also an adjustable electric thermometer, in precisely the same manner as an electric bell; the ventilator in this case taking the place of the bell. By reference to the illustration it will be seen that the electric thermometer is set on the cold side at 58°, and on the heat side at 60°; but the thermometer can be set to any other degree desired.

The action of the apparatus is as follows, supposing the ventilator to be shut :—Immediately the mercury in the heat tube rises to 60° it makes contact with the wire Q, completes

the electric circuit, and converts the electro magnets J K into powerful magnets; these attract the piece of iron L, and throw the rod M to the right, taking with it the connecting rod F, and opening the slips D by placing them at right angles, thereby allowing a current of air to pass between them and the slips C. At the same time a disconnection of the electric current takes place (thus relieving the battery entirely) by means of the prong marked T, which throws the buckle B R on to point W, the connecting point of the J or shutting magnets. The current is likewise disconnected when the ventilator is shut by the point U, in the same manner but in the opposite direction. The ventilator having been opened a catch marked P slips into a slot marked X X, thus locking the D slips. When the return current sets in (which occurs immediately the mercury in the cold side of the thermometer rises and touches V) the catch P is attracted by the electro magnet O and drops into X X immediately, thus locking the slips when shut.

The entire apparatus is in every way self-acting, and the inventor states that the working parts can be made so as to stand any amount of hard work, the electric parts being thoroughly secured from dust, damp, or accident by being enclosed in a box which can be fixed in a convenient position in the house.

How far the system can be carried out in a practical manner, and to what extent it can act serviceably in the moving of a long series of ventilators, can only be determined by further experiment. We can only say that the model acts well, and as it pertains to a subject of great importance the invention is worthy of being submitted to the public in a form as intelligible as we have been able to obtain.

CERTIFICATING SEEDLINGS.

YOUR correspondent at page 184, who does not see the equity of granting certificates to Cyclamens while such honours are denied to Cinerarias, herbaceous Calceolarias, and Pelargoniums, does not state the case exactly as regards the Pelargoniums. As I understand it, the Floral Committee refuses to award certificates to seedling Pelargoniums that are sent for adjudication without names. That a great number of named seedlings are certificated annually by the Committee is of course a question beyond dispute. The fact of the Committee declining to recognise unnamed Pelargoniums has, therefore, nothing to do with the question of making awards to such plants as Cyclamens, Calceolarias, and Cinerarias, individual varieties of which cannot be raised true from seed. I am at one with the Committee on the latter point; but if any of the three plants named could be propagated by cuttings as easily as seedling Pelargoniums, or by any other means so long as they can be kept true, then undoubtedly they would be worthy of the coveted honour, and the Floral Committee I am sure would be the first to recognise the justness of their claim to consideration. While a plant, or any particular class of plants, cannot be kept true by propagation in some way it has no claim to a certificate, but it is another thing to commend any particular strains, say, of Cyclamens, Calceolarias, or Cinerarias.—SABRINA.

YOUR correspondent on page 184 suggests that unless plants "come true from seed" it is not right that they should be honoured with certificates. That can scarcely be a satisfactory condition of determining the point, for surely if they can be reproduced with certainty by any mode of propagation they are worthy, when their merits are of an exceptionally high order, of being awarded the honours in question. Pelargoniums are not raised true from seed, but they are readily increased by cuttings: hence a rule of the Floral Committee prevents certificates being awarded to "yearly seedlings," which probably means that Pelargoniums must be propagated by cuttings in order to show the character and habits of the plants before new varieties are certificated. But then Cinerarias can be increased from offsets, and thus be kept true to name as well as Pelargoniums can be perpetuated by cuttings, and yet Cinerarias are not eligible for certificates, however meritorious the varieties may be. Cyclamens, on the contrary, are awarded the coveted honours, and they cannot be increased nearly so readily by division as Cinerarias; in fact varieties of both plants are in practice increased in the same manner—that is, by seed, and neither of them can be relied on to come true to character by that mode of increase. As a matter of fact Cinerarias, Calceolarias, and Cyclamens are equally valuable as staple decorative plants, and stocks of them are raised in the same manner—i.e., from seed. That being so, would it not be preferable to grant certificates of honour to exceptionally good collections of those plants as "strains," instead of singling out particular varieties of one genus and passing over those of the others, however meritorious the varieties may be?—A SPECIALIST.

CAMELLIAS AT WALTHAM CROSS.

VISITORS to the recent meetings of the Floral Committee at South Kensington cannot fail to have admired the beautiful boxes of Camellia blooms which have been exhibited by Messrs. Wm. Paul & Son. Arranged in the same manner as Roses, the effect produced was quite as imposing during the dull period of the year as are collections of Roses during summer. But however imposing cut blooms of both Roses and Camellias are when neatly arranged in fresh green moss, they do not afford quite sufficient means of determining the relative value of the several varieties for general decorative purposes. If in the case of Roses much depends on the habits of the plants in estimating the usefulness of the varieties, still more is it necessary to judge Camellias by the same rule, for they vary in their habits of growth and character of flowering much more

than do Roses. For instance: Camellias which are represented by grand blooms in the exhibition box may only be seen on straggling or scrubby plants at home, and as both the growth of the plant and condition of the foliage of Camellias are almost or quite equal in importance to the beauty of the blooms, it becomes necessary to inspect the plants to form a satisfactory estimate of the value of the varieties. Than a visit to a nursery where these splendid winter-flowering shrubs are extensively cultivated no better opportunity can be afforded for the purpose suggested. Camellias at Waltham Cross are about as prominent a feature in winter as Roses are in summer. They are in fact cultivated as a speciality, the selection of the varieties being both numerous and choice, and the plants are in splendid condition.

Two large houses are devoted to the plants, which are nearly all grown in pots and tubs, and a large number are also accommodated in brick pits. The plants are propagated on the premises, cuttings being taken from plants of the old single-flowered species, which are planted out for affording a supply. These are struck in the propagating house, and the large batches now in process of rooting prove that the cuttings strike as surely if not so quickly as Pelargoniums, for scarcely a "miss" was to be seen. These when established are grafted with the choicer varieties, and the plants are grown on a steady manner which is conducive to their permanent health and to their prolonged thrifty condition. The soil in which they are grown is light turfy loam with a slight admixture of peat and silver sand, and that this compost is suitable the excellent condition of many splendid specimens testify. Although these cannot be severally noticed, a magnificent example of *Imbricata* must not be passed in silence. It is growing in a tub, the plant 14 to 15 feet high, and 7 or 8 feet in diameter. It is handsome in shape, is laden with large flowers, and its dark glossy foliage falls to the surface of the tub. A better example of superior culture it would be difficult to find.

The plants are potted and pruned in the autumn after the buds are set. By potting in spring longer and fewer growths are obtained, but for securing closely-grown plants combining robust health with a great profusion of flowers, autumn potting and pruning are preferred in this nursery, and the condition of the plants affords ample evidence of the soundness of the mode of culture that is practised.

In one house the plants are grown solely for affording cut blooms. The shape of these plants is not considered at all, they are simply "cut about anyway," just as the blooms and sprays of blooms are wanted. The plants in this house are not grown for sale, but only the crops of flowers they produce are considered. But in the other, the principal house, a different system is practised. The blooms produced here are only gathered for wiring, and pruning is afterwards done in a systematic manner, and is subservient to the health and well-furnished condition of the plants. This house, a span-roofed structure, is 117 feet long by 30 feet wide. A border is arranged along the sides of the house, and there are beds on both sides of the central walk. There are thus three walks or avenues of plants, and their appearance now the plants are in bloom is remarkably fine. Amongst the great number of varieties flowering the following were conspicuous by their general excellence:—

WHITES.—*Alba plena*.—This old favourite is still one of the most useful by its free growth, the profusion of flowers, and purity of colour.

Fimbriata.—This chastely beautiful and pure Camellia is not always seen in satisfactory health, but here it is growing even more freely than the old Double White. *Fimbriata* should be in all collections.

Centifolia Alba.—A noble flower, round, smooth, large, pure, and very fine. A splendid variety.

Montironi vera.—Fine all round. Flowers large, cup-shaped; petals of great substance, mostly pure white but occasionally tinted with rose; foliage fine. Excellent.

Princess Charlotte.—A massive and noble flower of excellent form. Plant vigorous; foliage large and rich; petals stout, white slightly tinted with rose. A grand variety.

Piam.—White, very chaste; flowers medium-sized and of excellent shape, petals imbricated. Very pure and very good.

Funny Sanchioli.—Plant free, foliage very fine; flowers large, well formed, and pure. A beautiful variety.

Alba Casoreta.—Habit of plant excellent; foliage fine; flowers large, full, flat, regularly formed, and pure. One of the best.

Countess of Orkney.—A well-known and deservedly popular

variety, free in growth and producing large tinted flowers profusely.

Candidissima.—Small, but very chaste and pure. Rather a delicate grower.

Lady Hume's Blush.—A well-known and useful variety, especially for affording cut blooms early.

Ninfa Egeria.—This the last of the whites to be mentioned is certainly one of the best. Habit of plant excellent; foliage medium-sized, rich, and glossy; flowers medium, cup-shaped, petals of great substance and very pure. Very floriferous and superior.

RED OR CRIMSON.—*Bealii*.—This is one of the latest as it is one of the brightest of all Camellias. It has more scarlet in its petals than any other variety. Very useful.

Maria Nicholas.—Bright crimson faintly striped with white; flowers of excellent form and imbricated; habit and foliage good. Excellent.

Rose de la Reine.—Rosy cerise, veined with crimson; petals round, imbricated, and flowers of excellent form; habit good. A splendid variety.

Archduchess Isabella de Toscani.—Deep rosy crimson; flowers large, full, and smooth; petals cupped and imbricated; habit good, and foliage fine. Excellent.

Madame Lebois.—Rosy crimson; flowers rather small; petals slightly pointed and arranged with geometrical precision. Perhaps the most perfectly formed of all Camellias.

Il Beduino.—Deep crimson, fine massive flowers of excellent form; plant robust. Very fine.

Coquettina.—Coral red; petals of great substance; flower smooth and well formed; habit and foliage fine. Very good.

Elatior.—Rosy crimson, veined and occasionally marbled with white. Growth very free, and plant extremely floriferous. A very useful variety.

Benneyi.—Rosy red, slightly striped; flowers very fine; habit and foliage excellent. A splendid variety.

Eximea.—Soft scarlet, fine wax-like petals; large flowers, habit and foliage fine. Very useful.

Rafia.—Rich crimson scarlet, sometimes tinted with white; flowers of excellent form; habit and foliage good. A superior variety.

Manara.—The last to be noticed in this section and probably the best. Colour crimson; petals rather pointed and of great substance, flowers of admirable form; habit of plant excellent. A grand variety.

ROSE.—*Madame de Strelaloff*.—Bright lively rose, flowers of excellent form; splendid foliage. Very good.

Sarah Frost.—Deep rosy pink. A medium-sized, charming, symmetrical flower. Very attractive.

Marchioness of Exeter.—Peach. A well-known, distinct, and useful variety.

L'Avenir.—Pink. Flowers large and finely formed; petals imbricated and of great substance; habit and foliage good. The best of its colour and a superior variety.

Lucretia Gazziana.—Rose banded with white; flowers large, flat, and imbricated; foliage and habit good. Very useful.

Halleyi.—Very deep rose, striped with white in the centre, splendid recurved outer petals; habit good. Fine.

Principessa Vidoni.—Deep rose, veined and striped in the centre; petals round; foliage small. A profuse bloomer and effective.

Bealii Rosea.—Bright rose. Free and very useful.

STRIPED.—*Tricolor*. Single. In form resembling the fine old single scarlet Corallina. Ground pure; blotches and stripes bright; stamens conspicuous. Distinct and attractive.

Souvenir de Emile Dufrene.—Rosy red, with a broad white band down the centre of the petals, which are pointed and evenly arranged; habit of the plant good. Floriferous and very effective.

Adelina Benvenuti.—Flesh colour, clearly striped and blotched with bright rose; habit of plant good. Very free and fine.

Bonomiana.—Colours clear and distinct; habit of plant and foliage good. A well-known and prized variety.

Such are a few of the most striking varieties from the unique collection at Waltham Cross. Other features of the nursery are worthy of notice, but cannot be referred to now.—VISITOR.

NOTES AND GLEANINGS.

At the ordinary floral meeting of the Royal Horticultural Society held at South Kensington last Tuesday the following

new Fellows were elected—viz., Right Hon. A. S. Ayrton, Lady Beauchamp, Hon. Isabel Calthorpe, Harold L. Coffin, Lieut.-General Rudolph de Salis, C.B., H. G. Elliott, Bartle G. Goldsmid, P. C. Hanbury, James Henry, Mrs. Huggins, W. G. Lysley, Lieut.-General Sir Thomas McMahon, Mrs. Nangle, Mrs. Simpson, Sir Julius Vogel, K.C.M.G.; Rev. B. Winthrop, &c. Miss Florence Williams and J. Rose were admitted guinea members. We understand that a legacy of £100 has been left to the Society under the will of the late Miss Parry of Ham.

— WE understand that a PREMIUM will be offered by some Fellows of the Royal Horticultural Society for species of the order of AMARYLLIDACEAE, of which due notice will be shortly given. It is very desirable that this beautiful and varied race of plants should be brought together if only for scientific purposes, as much confusion still exists amongst them.

— WE have the authority of Sir Joseph Hooker for stating that botanists, students of natural science, professional gardeners, and artists are admitted to the Royal Botanic Garden at Kew every day at an earlier hour than the general public on making application to the Director, who will at once issue an order for admission.

— WE recently noticed a WHITE PRIMULA of considerable promise in the nursery of Messrs. J. Laing & Co. at Stanstead Park. So distinct is it by its purity, form, and substance of petal that it has been named Princess Louise. The name, however, was not given until it had been proved to come quite true from seed. It originated in the nursery, and it is quite expected that it will become an established favourite of this indispensable winter flower.

— WE last year spoke approvingly of the dwarf free-flowering RHODODENDRON EARLY GEM as an effective decorative shrub for both the conservatory and shrubbery. The plants exhibited by Messrs. Veitch at South Kensington on the 5th inst. afforded sufficient evidence of the value of this early dwarf and floriferous shrub, for although only dug up from the nursery on the day previous they were a complete mass of rosy purple flowers, so much so that the small dark green foliage was almost hidden. The plants were only about a foot in height; the individual flowers were from 1 to 2 inches in diameter, and produced in moderate-sized compact trusses. They were much deeper in colour than those produced by plants which were exhibited earlier in the season and which had opened under glass. This is one of the most distinct and effective of dwarf-growing shrubs for early spring decorative purposes.

— FROM the schedule of the Spring Show of the Botanical Society of DURHAM, NORTHUMBERLAND, and NEWCASTLE-UPON-TYNE we gather that the admissions to the Newcastle Shows during 1877 numbered 35,000, a fact which shows that the spirited efforts of the managers and the excellent exhibitions were duly appreciated. The spring Show of the present year is announced to be held in the Town Hall and Corn Exchange on April 3rd and 4th. In order to encourage gentlemen's gardeners a class has been added from which nurserymen are excluded; it has also been decided that no exhibitor can take more than one prize in each competition. The schedule is comprehensive and well arranged, there being altogether ninety-four classes. The plant classes, which include forced shrubs and greenhouse plants, in section A are open to all, as also are the classes for bulbs in bloom, and the classes for cut flowers of Rhododendrons, Azaleas, Camellias, Roses, &c. In the same section classes are provided for ladies only. Section B, which comprises upwards of thirty classes, is open to all, nurserymen excepted; and section C, upwards of twenty classes, is limited to amateurs only. Provision is thus made for every type of exhibitors, and as the prizes offered are liberal, exceeding in value £185, an extensive display may be anticipated. The total amount of prizes provided for the three exhibitions of the year exceeds £700.

— AMONGST the many ornamental plants in Mr. B. S. Williams's conservatory at Holloway few are more striking than ARAUCARIA COOKII. This Araucaria, which is presumably a variety of A. excelsa, combines in a remarkable degree massiveness with elegance. The dense branches droop gracefully, which renders the plant, or rather miniature tree, highly attractive. Another variety of the same species, A. excelsa robusta, commands attention by its flat rigid branches, the topmost tier of which has a singular effect by the five branches composing it subdividing into clearly defined triangles growing with geometrical regularity, and which are

rendered the more striking since they form the very tops of the plants, the leaders not as yet having made any growth. These and other *Araucarias* of the same type are highly ornamental in a small state, and are well adapted for various purposes of decoration.

— FEW hardy flowers are more effective during the spring and early summer than **PANSIES**. Both the show and fancy varieties are represented in colours as brilliant as are to be found in any other flowers. The bedding **Pansies** (*Violas*), are also extremely gay when planted in masses. In order to produce not only good blooms but a long continuance of them, the importance of early planting, especially in the south and in dry districts, cannot be too emphatically urged. If the planting of **Pansies** were completed before the middle of March instead, as is not unfrequently the case, being deferred until May, we should hear fewer complaints of the transient beauty of this beautiful family of hardy plants.

— It is gratifying to observe that in comparatively small gardens excellent practice is often to be found. We recently had the pleasure of inspecting the garden of J. Boustead, Esq., at Cannizaro House, Wimbledon, and were much pleased with the condition of the pleasure grounds and health of the plants. *Cinerarias* had foliage more than a foot in diameter, and with proportionally large flowers and no insects. *Clerodendron splendens* planted out and trained on the back wall of a stove has produced large and brilliant scarlet trusses throughout the winter, and continues producing them still; and the not less brilliant *Gesnera macrantha* merits notice on account of the intense velvety richness of its fiery scarlet tube-shaped flowers. The grounds also contain noteworthy specimens of trees and shrubs, and the whole aspect of the place betokens good management on the part of Mr. Jordan the gardener.

— AS attractive lawn ornaments few shrubs are more effective than well-grown and carefully managed specimens of choice **HOLLIES**. Some moderate-sized yet very beautiful examples are established in the Misses Christy's gardens at Coombe Bank. Besides well-trained specimens of the Gold and Silver Queen varieties, some distinct pendulous forms, both green and variegated, are especially ornamental. The weeping character of these is as decided as that of the drooping *Ash*, and the effect produced both in winter and summer is excellent. The condition of these handsome shrubs reflects much credit on Mr. Moorman, the gardener, and their appearance suggests their great value for either large or small lawns. The present is a very good time for transplanting **Hollies**, but it is important that the roots are kept moist during the process of removal.

— THE BOROUGH OF HACKNEY (late Stoke Newington) **CHRYSAETHUM SOCIETY** have issued their schedule, from which we observe that amongst the prizes offered are four silver cups—one by the Westminster Aquarium Company (where the show will be held) for six plants in 8½-inch pots; two by the Society for the best twelve and twenty-four incurved cut blooms respectively; and one by Messrs. Dixon & Son, Amhurst Nurseries, Hackney, for twelve blooms of Japanese varieties.

— PART 3 of vol. v. of the "JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY" is a sober pamphlet containing classified reports of *Violas*, also reports of *Clarkias*, *Iberises*, *Viscarias*, and *Godetias* grown at Chiswick in 1877. The *Elixir* or Buffalo Horn Manure is also favourably alluded to, and there is a complimentary notice of the late Mr. Andrew Murray, who was the Society's Scientific Director and Editor of the Journal in question.

WORK FOR THE WEEK.

KITCHEN GARDEN.

LIGHTLY fork over *Asparagus* beds, placing the rough portion of the surface soil, &c., in the alleys, where it should be pointed-in preparatory for growing *Cauliflowers*. The plants when strong and well hardened-off may be planted one row in each alley 18 inches to 2 feet apart. In the south this may be done now, but in cold localities the planting of the *Cauliflowers* may be delayed until the end of the month, or later if the weather be unfavourable. Prepare the ground intended to be planted with *Asparagus*. It is necessary to mix a quantity of well-decayed manure with the soil, which should be loosened to a depth of 2 feet or more by trenching. *Asparagus* prefers a rather light moist soil, yet free from stagnant water, and it can hardly be too heavily manured. Seaweed and sea sand are good additions to

the soil for this crop, as also is vegetable refuse. We plant in beds 4 feet wide, placing three rows of plants in a bed, with 2-feet alleys between the plants, which are 1 foot apart. Planting is proceeded with as soon as the tops of the seedlings are an inch or two long. Any *Seakale* too small for forcing and which has been kept in moderately moist soil or sand should have the crown or growing-point cut off and then planted in rows 18 inches apart, the sets being a foot asunder. Portions of the young roots of the thickness of the little finger may be cut into lengths of 4 to 6 inches, and be planted at the same distance. Seed of *Seakale* may also be sown now in warm situations, but defer sowing for another fortnight in cold localities and positions. Plant *Cabbage* plants in their permanent quarters, including the Red for pickling purposes. These remarks apply to the August sowing, the plants having been transplanted in beds. A planting made now succeeds those planted in late summer or early autumn.

HARDY FRUIT GARDEN.

Fig trees against walls may now have their winter covering removed, keeping, however, protecting material in readiness for use in case of frost, but in all mild weather the trees are better exposed. Pruning may be performed, but we prefer to defer it until the young fruit appear; indeed if due regard has been had to summer pruning and stopping not much pruning at this time will be necessary. Only the strongest and least ripened shoots should be taken out, thinning also the short-jointed fruitful wood, as the fruit under a mass of leaves does not ripen so well as that having the advantage of light and air.

Strawberries are occasionally planted at this season, indeed we can remember the time when the practice of spring planting was general and good crops were obtained: that mode is, however, generally too "slow" for the present advanced age. The ground for Strawberries should be trenched and well manured unless already done. Good well-rooted runners being at command, leave the plants until they are starting into growth, and then transplant them with balls. They should be planted 2 feet apart each way. Strong-growing kinds, such as *President*, should have 2 feet 6 inches distance between the rows. We do not keep Strawberries on the same ground for more than three years. In light soils annual or at most biennial cropping is preferable.

It is not usual to protect the blossom of the Pear and Plum trees on walls, but it is very desirable to do so, as it may make all the difference between a full crop or a scant one should severe frost prevail. Canvas screens are not very expensive, and the fruit preserved by them would in many instances pay for their cost in a season. The netting employed for protecting fruit from birds is often when placed over the trees now of a double thickness effectual in protecting the blossom from frost; it possesses the advantage over canvas of not requiring to be removed daily in bright weather. There would be less blistered leaves and very little canker if the foliage were protected from the sudden and often severe cold of our spring months. Dry fronds of the *Bracken* are very suitable for sheltering the trees. They may be strung together with twine and be secured to the wall at intervals. Cherries on walls are also deserving of having the blossom protected, as also are espalier trees and pyramids of choice Apples and Pears. The protecting material should be in readiness for application by the time the blossoms show colour. Some material for protection will suggest itself corresponding to the means of the several cultivators, but protection of some kind must be afforded the trees when in bloom and the weather is severe.

FLOWER GARDEN AND PLEASURE GROUND.

Lawns having become brown and patchy should be well scratched with an iron rake, a little fine soil spread over the places, well raked again, and then sown with grass seeds and be well rolled. Those having plenty of grass but weak, and who object to a top-dressing of compost as before advised, or if such compost is not available, may apply equal quantities of soot and wood ashes to the lawn with much benefit, spreading on the mixture at the rate of a peck per square rod. Proceed with the pruning of *Roses*. In cold districts pruning should be deferred until next month. For a later bloom the pruning may be postponed until the middle of April in the south, and north of the Humber until the end of that month. We shall not give any directions for performing the operation after the sound and timely hints given by "WYLD SAVAGE" in a recent issue. Point-in manure, and remove any litter that has been used for protection.

Evergreen shrubs may now be pruned. Laurels, Portugal and common, especially the latter, become straggling and do not do so well as when well pruned. Both kinds may be cut hard in, and they will recover in a short time, forming much finer heads or bushes than when left to themselves. *Hollies* and *Yews* bear pruning well, as do *Laurustinuses* immediately after flowering. Symmetry of form should be the object aimed at—not the stiff formality of clipping and shearing, but assisting Nature by the removal of gross and irregular growths. *Rhododendrons* do not require much pruning, but irregularities should be removed, and if the shrubs are too large they may be cut-in closely. *Conifers* need very little pruning, but duplicate leaders should be removed, and any growths that are likely to disfigure the head should be

shortened. Roll walks frequently, turning the surface if full of small weeds, and applying a little fresh gravel.

Propagating Bedding Stock.—Attend to the increase of such plants as have been placed in heat to afford cuttings, and if there is likely to be a deficiency of plants from cuttings supplement them by sowing seeds. Seed of *Lobelia* should be sown at once in gentle heat to have good plants by planting-out time. Old plants placed in heat will afford a quantity of cuttings, which strike readily. Golden Feather may now be sown in cold frames placed in a warm situation, and better plants will be produced than those raised in heat. Golden Chickweed is also better increased from seed than by cuttings, both of which are easily raised in a cold frame. Various perennials, such as *Delphinium*, *Dianthus Heddewigii*, &c., flower the first year if the seed is sown early in gentle heat, pricking off the seedlings in due time and growing them on. Sow seeds of Ten-week Stock, Asters, Marigolds, and *Phlox Drummondii* in gentle heat for the principal summer display. All seedlings when large enough to be handled should be pricked out and be kept near the glass, and well ventilated so as to have the plants sturdy.

FRUIT HOUSES.

Pines.—The young roots, especially of vigorous plants, are tender and susceptible of injury from too much bottom heat; therefore the bed should be frequently examined, and suckers or young plants recently repotted should also be examined, and when roots appear at the sides of the pots a lessened bottom heat will suffice; for though 90° or a few degrees more may facilitate speedy root action, 85° is safer when the roots reach the sides of the pots. The pots should be raised if the temperature of the bed is excessive. The plants require to be regularly watered as they make roots rapidly, and they must not be allowed to become dry nor root-bound, or they will receive a serious check. In order to secure good results the plants must make steady progress; therefore have the material for potting in readiness, and shift the plants promptly when they are well rooted. Fruiting plants and those in or near flowering keep at 65° to 70° at night, 75° to 80° by day, with an advance from sun heat to 90°, closing at 85°, damping all available surfaces at the same time. Attend to the watering, &c., of succession, indeed to all plants, and the water should not be less in temperature than that in which the roots are.

Cherry House.—The trees are now in blossom. Syringing may be discontinued, but a light sprinkling in the early part of the day will be judicious in bright weather, also damping in the afternoon all available surfaces, for Cherries as well as Peaches, and particularly Plums, are not so susceptible of injury to the blossom from a light sprinkling overhead as by a close moist atmosphere. The borders must be well watered, particular care being had in that respect to trees in pots. Ventilate freely whenever the weather is favourable, and if artificial impregnation is resorted to let a bright day be chosen if possible for the operation. A little air should be left on constantly day and night at the top of the house. Keep the night temperature at 45° to 40° at night, 50° to 55° by day from fire heat, increasing the ventilation at 55°, having full air on at 65° and closing at 55°. Fumigation is the best remedy for aphids, but it must be done moderately or the foliage will be injured.

Strawberries.—It is a capital plan to have a house specially provided for the swelling-off of the fruit, which then attains a much higher quality than when it ripens on shelves in structures the inmates of which require treatment adverse to the swelling-off or ripening of Strawberries. In bright weather 80° to 85° should be a maximum, closing at the latter with a copious moisture obtained by sprinkling. La Grosse Sucrée has ripened fruit a week to ten days in advance of Vicomtesse Héricart de Thury, both having been started early in December. The last batch of plants should be placed in their fruiting quarters, or at least in frames, without delay, so that they may be making progress. Plants swelling the fruit assist with liquid manure, and to such as are to be placed on shelves remove a little of the surface soil and replace with fresh, seeing that the drainage is clear and the pots clean. It is well worth while to impregnate the flowers, it being expeditiously done with a good-sized camel's-hair brush. Aphids destroy by fumigation, and "spittle fly" by removing the insects beneath the froth. Red spider keep under by syringing the under side of the leaves, but this pest is not troublesome when the plants are well supplied with water or liquid manure, the plants being examined for the purpose twice a-day.

PLANT HOUSES.

Greenhouse.—Complete the necessary potting of all the hard-wooded plants as soon as possible, such as *Aphelexis*, *Acrophylum venosum*, *Chorozemas*, *Diosmas* or *Adenandras*, *Droophyllum gracile*, *Eriostemona*, *Eutaxias*, *Metrosideros*, &c., and as the sun is more powerful and March proverbially windy the admission of side air should be given cautiously, allowing a slightly higher temperature rather than admit drying currents of air, especially to plants recently repotted. Early-flowered *Cytisanes*, *Epacris*, and *Acacias* out of bloom should be cut-in, and if kept rather warmer they will soon break, and may then be repotted. They will flower early without much forcing. *Coronillas* may be treated in the same manner. Cuttings of *Monochaetums* should now be

inserted, selecting the young shoots when 2 or 3 inches in length, and placing the cutting pots in gentle bottom heat. *Libonia floribunda* may be treated in the same way, young plants grown on through the summer being more serviceable than old plants. Pot *Statice* and similar plants at once, not omitting *Witsenia corymbosa*, one of the finest of late summer-flowering plants, its fine blue flowers being very desirable. *Plumbago capensis* must have a light airy situation. Plants kept in small pots over the winter should be cut back, and when started into growth shifted into pots 1 to 2 inches larger, 6 to 8-inch pots being quite large enough for decorative purposes. *Agapanthus umbellatus* afford a light situation, and if additional stock be wanted divide the old plants. Any plants in small pots shift into larger; the sky-blue flowers are very useful. *Imantophyllums* assist with weak liquid manure, and *Richardias* likewise. They are gross feeders, and amply repay by the increased size of the spathes for any extra nourishment. Repot *Lapagerias* and other climbing plants grown in pots.

Increase and Propagation of Plants.—Pot a good batch of tuberous-rooted *Begonias*, and disroot and repot such sorts as *B. Dregei* (*parvifolia*) and *Weltoniensis*, and place them in gentle heat. *Gloxinias* and *Achimenes* should also be forwarded in gentle heat, such as that afforded by a hotbed; they are very serviceable for a greenhouse in summer. Insert cuttings of Tree *Carnations* in sandy loam, and place the pots in gentle heat. The cuttings speedily emit roots, and the plants should then be hardened-off, potted, and placed outdoors in summer. *La Belle*, *Miss Joliffe*, *Princess Christian*, *Princess Beatrice*, *Marchioness of Westminster*, *Rose Perfection*, *Queen of the Belgians*, *Scarlet Defiance*, *Empress of Germany*, *Zouave*, *Monsieur Baldwin*, and *Prince of Orange* (*Picotee*), are a select dozen. Pot-off early-struck double *Petunias*, inserting more cuttings; and cuttings of Zonal *Pelargoniums* may be inserted now to afford plants for flowering in autumn and winter. Pot and grow-on for summer bloom such plants as have been wintered in small pots, affording weak liquid manure to those advancing for bloom, and do not neglect the stopping and regulating of the shoots when they require it. Also pot and grow-on *Pelargoniums* cultivated for their foliage, and do not omit the scented sorts, such as *odoratissimum*, *denticulatum*, *capitatum major*, &c. Insert cuttings of *Bouvardias* and *Abutilon* *Boule de Nieve*, placing them in gentle heat, and grow the plants on for winter flowering; also cuttings of *Fuchsias* for late bloom. Keep Show *Pelargoniums* near the glass, tying and regulating the shoots, feeding the plants with liquid manure unless they are very robust, shifting into larger pots those for late bloom, also *Calceolarias*. Sow *Mignonette* in gentle heat for affording plants for growing in pots. *Reseda odorata* *Queen Victoria* is a fine variety. *Primula sinensis* vars. sow in heat for autumn flowering, also *Balsams* and other tender annuals for the decoration of this structure at a later period. Pot-off *Chrysanthemums*; those already potted-off and which have filled the pot with roots shift into larger pots, stopping the growths when about 4 to 6 inches high if specimen plants are required, and keeping them in a cold frame and well ventilated. Cuttings may yet be inserted; they strike quickly in gentle heat. *Echeveria retusa* is one of the best succulents for winter flowering; cuttings root freely kept rather dry either with or without heat. Repot *Hydrangeas*, and place a portion of the plants in gentle heat for early flowering. *H. hortensis*, *H. Thomas Hogg*, *H. stellata* *flore-pleno* are good, the latter being very useful for furnishing; *H. paniculata grandiflora* having fine heads of creamy-white flowers. Syringe any plants infested with red spider, such as *Chorozemas*, *Pimeleas*, *Eutaxias*, &c. Fumigate with tobacco upon the first appearance of aphids or thrips, and remove brown and white scale with an approved insecticide. Pot more Musk and place in gentle heat.

Conservatory.—This structure will now be at its gayest. Any plants at all "seedy" looking should be removed and replaced by others from the forcing pit. Continue to introduce to the forcing pit *Ghent Azaleas*, *mollis* var., *indica* var., *Rhododendrons*, *Kalmias*, *Lilacs*, *Laburnums*, *Hawthorns*, *Viburnums*, *Prunuses*, *Deutzias*, *Spiræas* *Thunbergi*, *arizifolia*, and *callosa alba*, *Clematises*, *Weigelas*, &c., *Lily of the Valley*, *Dielytras*, *Spiræas* *palmata*, *venusta*, *filipendula*, *Ulmaria*, and *japonica*, with such bulbs as it may be desirable to forward. A good batch of *Liliums* should be forwarded in heat, especially *L. longiflorum* and *L. auratum*. The retubbing of such plants as require it should be seen to at once, and all plants in borders to be supplied with water according to their requirements, attending to top-dressing, &c. Tree Ferns will be starting into growth and require very copious supplies of water. *Camellias* as they go out of bloom should be top-dressed. We use old dry cow dung, removing a little of the surface soil. This treatment answers well also for the Orange family, promoting surface roots. Orange trees are subject to attacks of scale; there is no remedy but frequent sponging of the leaves on both surfaces with soapy solutions. *Camellias* may be cleansed in a similar manner, but the sponging must be done before the plants commence growth or the tender young shoots will be damaged. Many plants, such as *Oleanders*, *Acacias*, *Lapagerias*, *Palms*, &c., are liable to white scale, which may be cleared with 1 lb. of soft soap to a gallon of water, adding a quarter pint

of spirits of turpentine, applying with a brush and syringing immediately afterwards.

TRADE CATALOGUES RECEIVED.

James Carter & Co., High Holborn, London, E.C.—*Illustrated Catalogue of Prize Farm Seeds.*

R. Edwards & Sons, Nuthall, Nottingham.—*Catalogue of Dahlias.*
Samuel Hawley & Co., Forest Gate, London.—*List of Garden Manures and Horticultural Requisites.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (*W. Henshaw*).—The book you refer to has been out of print for years, but we can procure you a copy. (C. A.).—Thomson on the Culture of the Vine.

GREEN ROSE (*E. E.*).—We do not know the origin or history of the Rose. It is very rare. The name is *Rosa viridiflora*, and the green colour of the petals is perfectly natural.

PROPAGATING AZALEA MOLLISS (*A Liverpool Subscriber*).—It is propagated in the nurseries by seed, layers, and grafting. Raising seedlings is a slow process, and not likely to be satisfactory in your case. Layering is effected by having the plants planted out, the branches being notched or twisted, and pegged into the ground in March. Plants are also increased by grafting on healthy stocks of *A. pontica*, the stocks being potted and side-grafted in March, and kept in a close temperature until the union is complete. Usually the most satisfactory mode is to obtain plants from the nurseries. When they are purchased in a small state they are not costly.

WHITE AZALEAS FOR FORCING (*J. Wallace*).—*Virginalis*, pure white; *Souvenir de l'Universelle*, white, striped with rose; *Purity*; *Princess Alice*, pure white, flowers of fine form; *Mademoiselle Léonie Van Houtte*, white, striped with rose; *Beauty of Dorking*, white, spotted with carmine; *Flag of Truce*, pure white flowers, large and double; and *A. Borris*, double white.

CULTURE OF PITCHER-PLANTS (*Puddy Carey*).—Now is the time to examine your Pitcher-plants to report them if necessary—that is to say, if the roots are found to have taken hold of all the soil given them in the last potting a little more will now be required in order to keep them in full vigour, taking especial care to avoid overpotting. See that the drainage is right. It should fill quite a fourth of the pot. The roots revel in a mixture of two parts sphagnum with one of very fibrous peat, having all the finer particles sifted out of it, and with a sprinkling of pieces of charcoal the size of a filbert. Pot firmly, and prune any long shoots for the sake of uniformity, but no regular systematic pruning is necessary after the plants are once furnished; otherwise, if they are of straggling habit they may be cut down nearly as closely as *Geraniums* are cut to promote a greater number of growths, and consequently pitchers. Pruning must only be done when the plants are in a thoroughly healthy state, the present being a suitable time for the operation. Keep the plants in a very high and moist atmosphere, and shade them from the sun.

PLANTS FOR A GRAVE (*J. H. Glasgow*).—This is a subject which scarcely admits of advice; the tenant of the grave, the relations, the burial ground, ought to influence the selection. We know a sod-covered grave where, the grass being very small-leaved, *Snowdrops* are planted for winter; these are followed sometimes by *Hyacinths*, and for the summer a few *Ferns* are used. Thus in the summer months flowers are altogether discarded, and nothing but the *Ferns* are seen, and the effect is at once quiet and graceful. For an ordinary grave the sexton is requested to leave the mound a little less than the usual size, and the remainder of the space is occupied by *Snowdrops* and *Ferns*. In addition to the appropriateness and good taste of this style of grave decoration, it possesses the advantage of requiring the very least of attendance. Both the *Snowdrops* and the *Ferns* will last for many years, and all that is required is an occasional cutting of the grass on the mound and the keeping the other parts free from weeds.

GARDENIAS SHEDDING THEIR FLOWER BUDS (*Constant Reader*).—The temperature you give would suffice for the Chinese and Cape species, but it would be much too low for such as *Devoniana*, *Stanleyana*, and kindred kinds, which should now be in an Orchid house to be flowered to perfection, or, what is equally good, plunged in the bed of a Pine stove. Besides unsuitable temperature, bud-shedding may arise from excessive drought or overwatering, or a sudden removal from a cold pit into a brisk heat. We should only pinch the gross-growing shoots, and should increase the temperature gradually.

HYACINTHS AFTER FLOWERING (*Various*).—The bulbs are only good for border culture after they have been grown in pots or glasses—that is, they will not produce such fine spikes as those produced the first year after the bulbs were imported. Yet with judicious management the bulbs grown in pots will produce useful spikes for cutting another year, and for this purpose we grow three to five bulbs in a 5-inch pot, or several bulbs in a pan. As soon as the flowers fade the spike should be cut off and the plants be placed in a light frame, and be watered as carefully as before they flowered, giving them weak liquid manure occasionally to promote a good growth of foliage. This must be kept green as long as possible, and must be ripened off in the full sun. After the plants have been in the frame for a time they may be planted when the weather is mild in light soil on a warm sunny border. After the bulbs have flowered in glasses we have found it a good plan to empty the water out of the glasses and fill them at once with leaf soil, working it well amongst the roots and keeping it moist, the plants being placed in a frame, treated the same as those grown in pots, and afterwards planted out. The bulbs may remain in the ground until August, or permanently if

they are not wanted for pot culture a second year. Those planted out and covered with a glazed frame always give us a valuable supply of cut flowers.

HERRACEOUS PLANTS TO FLOWER IN JULY (*Midland Counties*).—*Campanula macrantha*, *C. pyramidalis alba*, *Delphinium Belladonna*, *D. Madame Henri Jacotot*, *Eupatorium angustifolium album*, *Eupatorium cannabinum*, *Galega officinalis alba*, *Geum coccineum grandiflorum*, *Helianthus multiflorus flore-pleno*, *Lathyrus grandiflorus Frederic splendens*, *L. latifolius albus*, *Lychnis Chalcodonica flore-pleno*, *Lobelia fulgens St. Clair*, *Enothera macrocarpa*, *Polygonum undulatum*, *Saxifraga longifolia*, *Spigelia marilandica*, *Spiraea Ulmaria foliis variegatis*, *S. palmata*, *S. venusta*, *Verbena venosa*, *Phlox decussata* vars. To have the required twenty it will be necessary to have more variety, and have duplicates or more of those required; indeed, we should not think of exhibiting twenty plants or cut flowers without having an extensive collection to select from.

PLANTING VINES (*E. H. Lichtfeld*).—Presuming that you do not intend forcing the Vines early, we think in the case of a house constructed as yours is that outside planting would be the most satisfactory. There would be danger of the roots becoming too dry in the narrow, elevated, inside border. Drain the border well and see that superfluous water can pass away freely, and plant the Vines outside, wrapping the rods with haybands between the soil and the apertures by which they are introduced to the house. If the Vines were under an experienced cultivator and ripe fruit was required in May we should plant inside.

SOIL FOR A VINE BORDER (*J. D.*).—Soil that will grow good vegetables will grow good Grapes; if you have such, use it. Avoid soil from a wood, as likely to contain the spores of fungi which prove hurtful to Vine roots. If the soil at your disposal is poor enrich it by mixing with every five cart-loads one load of mortar rubbish, one of wood ashes (to be had from a baker), one of old well-decayed dung, and 3 cwt. of crushed bones. Twenty feet is the width of a first-class Vine border, but it need not be more than half that width for the first three or four years. Black Hamburg is the best Grape for general purposes, and your house 30 feet long will require six Vines.

PLACING STRAWBERRIES IN POTS IN SAUCERS (*C. E.*).—It is not desirable to place the pots in saucers half filled with manure, and that in a fresh state. Fowls' dung is a powerful fertiliser and should not be used for such a purpose, even if sand has been mixed with it for a year. We find better results without saucers, the plants being watered with liquid manure after the fruit is set and swelling freely until it changes colour for ripening. One peck of fowls' dung to thirty gallons of water forms a good liquid manure. We know of no means of rendering fresh dung fit for immediate use for mixing with soil for potting except by drying it over a fire or other heated surface, though much may be done by mixing with very dry soil. A very moderate quantity of fowls' dung should be mixed with the soil for potting plants, not more for gross feeders than a tenth. To burn the fresh dung would destroy its organic value.

TRANSPLANTING RASPBERRIES (*A Cheshire Subscriber*).—If it is only a question of removing canes from one part of a garden to another, so that there is no danger of the fibrous roots becoming dry by exposure to the air, we should not hesitate to transplant the canes now. We should, however, not dig up the entire plantation, but should only thin out the canes and plant such as have an abundance of fibrous roots near the surface, leaving the others for another year to prevent a blank in the fruit supply. The canes removed should be shortened to within about a foot from the surface of the soil, which will promote the growth of stronger canes for fruiting next year.

PLANTING POTATOES (*G. S.*).—A dressing of lime alone is insufficient; supplement it with a heavy dressing of your stable manure immediately, then when the soil is in working order draw drills 30 inches apart and place the sets a foot apart in the rows, drawing the soil over the Potatoes with a Canterbury hoe, covering them 4 inches deep. When the young shoots become visible above the surface pass a hoe through the surface of the ground to destroy weeds, stir the soil between the rows with a light steel fork, and at the same time earth-up the Potatoes with the fork, thus leaving the soil clean, light, and open to the action of the air, inducing a strong rapid growth, and avoiding any further trouble with weeds, as the haulm soon meets and keeps them down. Have nothing to do with steeping in petroleum. Choose good well-ripened seed of fair size, plant it in soil that is well stirred and enriched with manure. Keep down weeds, and stir and earth-up before the growth is much advanced. Lift the crop as soon as it arrives at maturity, and with favourable weather you will probably be more successful than if you attempt any more elaborate process of culture.

DRAWING DRILLS FOR PEAS (*An Amateur*).—In gardening practice we do not know of a better implement for drawing the drills than the hoe. There are implements for drawing drills for such small seeds as Carrots and Onions; but even in the case of those crops, and when the land to be sown is of comparatively limited extent, we prefer the corner of the hoe for forming the drills, these being drawn by the side of the garden line tightly stretched.

NITRATE OF SODA (*A Constant Reader*).—It is popularly known as cubic nitre or cubic petre. One pound to 30 square yards of land is a sufficient quantity as a manure. Plants probably decompose it. In the above quantity it has been found beneficial to Carrots, Cabbages, lawns, and Potatoes. Dissolved in water, 1 lb. to twelve gallons, it has been used with advantage as a liquid manure to Lettuces, Celery, Chrysanthemums, Dahlias, Fuchsias, Carnations, and Pinks.

BLASTING TREE STUMPS.—"A Forester" writes in answer to "Puddle" that he has blasted many roots by the old method of boring a hole in the stump with an inch wimble, the hole reaching as near to the centre of the root as possible, filling the hole with coarse blasting powder to within 3 inches of the top, and filling to the surface with moist clay hammered very firmly. The powder is also pressed very firmly with a hard wooden rammer. Previous to placing in the clay one end of a fuse is inserted in the powder, the other passing through the clay for the purpose of being lighted. If shelter is near the fuse need only be short, but if the roots are in the open the fuse must be longer, so that when lighted it does not ignite the powder before the operator has retreated to a safe distance from the point of explosion. A little experiment as to the time a given length of fuse will burn will suggest the length required for any particular site or operation. Our correspondent states that he has blasted roots very successfully by that plan, and has never met with or seen an accident occur to those engaged in the work.

LIME DRESSINGS FOR GARDENS (*South Hants*).—Much caution is required in the use of gas lime, and we should mix it with a heap of garden refuse, and turn the heap over a few times before applying it to garden crops;

then given in moderation it would do good. Pure lime, on the contrary, may be applied unmixed at the rate of eighty bushels per statute acre on light soils, and from a hundred to two hundred bushels on medium and heavy soils. As much as three hundred bushels have been used with benefit upon very heavy wet soils.

HEATING APPARATUS FOR A GREENHOUSE (*Idem*).—A hot-water boiler and iron piping is best.

HEATING CONSERVATORY (*Mrs. Ashley Maude*).—A conservatory 21 feet by 13 feet and 15 feet in height cannot be heated satisfactorily by an oil stove. Two such stoves would not mend matters, being alike inefficient and very expensive. A slow-combustion boiler would probably answer, having two rows of 3-inch pipes all around the house excepting the doorways. We should have a stokehole outside and heat with a flued saddle boiler and 4-inch pipes, two rows up the pathway all round the house in an open flue, covered with ornamental iron grating, or four rows of piping if the path only extends the length of the house. A rough plan would have enabled us to be more explicit.

PETROLEUM STOVE (*Inquirer*).—We have seen testimonials in favour of that manufactured by Messrs. Dick Radcliffe & Co.

GREEN FLY ON GOOSEBERRIES (*E. Richardson*).—Syringe the Gooseberry bushes with a solution of Gishurst compound in the proportion of 3 ozs. to the gallon of soft water.

NAMES OF PLANTS (*T. B. D.*).—*Amaryllis blanda*, or Blush Lily, found by Sir Joseph Banks at the Cape of Good Hope. (*W. G.*).—The specimens are insufficient. You can send anything under an ounce weight for a penny. Send us better specimens and in bloom. (*Jean*).—1, *Santolina Chamaecyparissias*; 2, *Picaria ranunculoides*; 3, *Anemone appennina*; 4, *Omphalodes verna*. (*J. S. E.*).—*Eriostemon baxifolius*. (*O. H. C.*).—*Maxillaria picta*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE CULTIVATION OF OATS.

We will write about the oat as lent corn, and postpone our observations relating to the winter oat until a future time.

The oat crop is commonly considered of less importance than any of the cereals, and is often put in anyhow or anywhere without much preparation or manure; but we have found it pay as well or better than other cereals, particularly upon heavy land or on the mixed soils, and in cold and exposed climates like Scotland, Wales, and various parts of the northern and north-western districts of England; and after an untoward season for wheat, like the past winter, seeding in proper time and condition has in some districts been impossible, and much heavy and difficult land for tillage has been left over unsown. In such cases the oat crop offers an eligible substitute for the wheat crop, as we have often found on land in good condition that as many quarters of oats per acre can be obtained as of sacks of wheat, and therefore at the relative value of each kind of grain the acreable produce will be nearly equal in money value. Oats are generally sown upon the chalk hill farms after saintfoin or clover lea, and also upon various soils, particularly the mixed loams, after a root crop. When sown out of lea the land should be ploughed and pressed early in the spring, in order that it may settle down firm, otherwise the wireworm often causes serious injury; but it is a safe plan when oats are sown out of lea to sow about 3 cwt. per acre of rape cake, which is a good manure for the oats, and at the same time it has the effect of attracting the wireworms. When oats are sown in good ground after turnips they are often mixed with barley in order to secure a regular plant, and also to increase the crop, which it does by about 6 or 8 bushels per acre; at the same time it is the best security against the depredations of the wireworm, because when the mixed grain is sown we have never known them eat both kinds, and we are pretty sure to obtain a plant of either one or the other when 2½ bushels of Tartarian oats and 1 bushel of barley are sown per acre. It is a common practice to sow oats very early, but we prefer to wait for a favourable season instead of sowing so early as to disregard the state of the land. Many say, "Oh! that will do for oats," but we have found that they grow slowly in such cases, and often lose plants in consequence, whereas when sown about the middle of March they come up and usually (particularly the early white sorts) go on well until harvest without a check.

We will now refer to the sorts of oat most in use. First and in general cultivation is the black Tartarian. The white Tartarian suits some soils. The early white varieties most in esteem are white Canadian and white Poland. Later sorts are white Water-

loo, also the French copper-coloured. Taking first the black Tartarian, and especially the pedigree stock raised by Major Hallett, we must say for general purposes they are about the best for land in general. They are selling at rather more money than the ordinary samples, but being pedigree stock it is not more expensive to seed an acre of land, because a bushel of seed less will suffice. The white Tartarian oat is a very heavy cropper, and used to be very long and light in the samples, but within the past few years we have noticed that by selection the samples have been much improved. This sort is much in favour for feeding cab and carriage horses, as many proprietors state that weight for weight they are the best oat they get. These oats are late to harvest, but the straw is much relished by cattle, and we have found it excellent fodder for fattening bullocks. It is also a good plan to mix barley with this sort. We have always in our own occupation been in favour of the white Canadian and white Poland oats, ours being a forward climate and loamy mixed soil. We often grow them before the turnip crop, and have often grown 9 or 10 quarters per acre weighing 46 to 48 lbs. per bushel, according to the season, but they require to be cut very early and whilst comparatively green, otherwise they soon shake out with the wind and much loss ensues. The early harvesting, too, is very beneficial to the straw, we having used it instead of hay for many years for cattle and horses in chaff with great advantage, and the value of green straw is capably illustrated by the excellent article by Dr. Voelcker, whose analysis of oat straw gives a very nutritious return, and which we find coincides entirely with our own practice for many years. We grow the early oats in preference to making a fallow for turnips, and our plan is to cut and tie into sheaves and set up the produce in stooks upon one-third of the land, and as fast as the oats are cut we proceed to plough between the lines of stooks, work down, and drill turnips every day as fast as the corn is out; the one-horse drill acts well in such a case when two-thirds of the ground are drilled before the oats are carted. When the turnips are sown the same day that the land is ploughed the seed is sure to vegetate, as all the moisture in the land is available in the driest of weather. We generally find these oats fit to cut about the 15th or 20th of July, and we usually secure a good crop of turnips by drilling about 1 cwt. of guano and 8 cwt. of bone superphosphate per acre, and the plant is much surer to take after a corn crop than after a fallow preparation, as they do not suffer from wireworm and grub. These oats we often sow after potatoes, which crop entirely rids the land of wireworm. For many years before we grew potatoes to any great extent we used to be troubled with wireworm, and found it very difficult to obtain a regular plant of lent corn or turnips either. The potatoes, however, when removed carry away the wireworms also, as they bury themselves just under the skin of the tubers, and we have never seen any damage to crops from this cause since we have made potatoes a part of our rotation of crops. The white Waterloo and French copper-coloured sorts are generally grown upon kind dry soils, and especially for late sowing. We have seen very fine crops grown on chalk, sand, and gravel soils, where the climate is mild and the aspect south or south-west. The later varieties of oats, such as the white Tartarian and French, can remain uncut until a much later period without serious loss by shedding of the grain, and for this reason they are sometimes selected for growth on exposed hillsides at a high altitude and situations which suffer from wind off the sea coast. The cutting and harvesting of oats is often thought of little consequence, and they are cut and left lying on the ground for a long time under ordinary management; but since straw has now attained a value little short of hay for feeding purposes more pains and trouble is taken with the crop, and to have the straw in the best feeding condition it should be cut and tied into sheaves of moderate size, and about 12 or 15 inches through at the bond, and in this way oats may be cut much greener, because there is little fear of loss of grain, as is often the case when harvested as loose corn, particularly when the crop has been lying on the earth for a considerable time, and in showery seasons sprouted grain is sometimes found amongst the samples harvested as loose corn, whereas when tied

and set-up in stooks of about twenty sheaves in each it is very rare that the grain is injured, nor can the straw be damaged and discoloured when the sheaves are looked to and kept set-up. Loose corn is, however, in a fine time not without its advantages, because it will be fit to carry to rick several days earlier than when tied into sheaves. The cost of tying the crop will be greater than forking and raking a loose crop, but the expense of carting will be much less, and since ricks are now usually made in the fields where grown the sheaved oats can be got into stack not only at little expense but in a very short time, which is of consequence in a catching harvest. There is one matter requiring particular attention, because when the crop is tied into sheaves they are very liable to heat in the stack, for it is a fact that no corn is so liable to heat, especially where clover is found amongst the crop; and as it is usual to sow clover seeds with this crop care must be observed in order that the clover may have sufficient time to become quite dry before carting, for although when heating in rick occurs if it arises from greenness only it will not injure the straw as fodder, but it will come for use like the American oat hay, yet the grain will be injured, and cannot be used as seed corn, the vegetating power being destroyed.

WORK ON THE HOME FARM.

Horse Labour.—Ploughing for the various crops will still be going on, drilling also and harrowing-in the seed at every opportunity when the weather is favourable of beans, peas, oats, barley, &c. Rolling the clover seeds and meadow land must be attended to, but it may be done after rain when the arable land is too wet for the ordinary tillage it requires. The odd horse will likewise find constant employment in fetching and carrying the commodities which now form the chief food of the animals on the farm, such as roots for the dairy cows and pigs, hay and roots for the horses, and hay and cake for the sheep; and where there is a milking dairy and the produce sold as milk, on the return of the light van which takes the milk to town or station many items required may be brought home as back carriage, such as grains for the cows and pigs, cake for the sheep and fattening bullocks, also manures of the kinds required may be fetched from the station, so that with a proper vehicle employed it need not be charged entirely to the milk trade, but will always be found useful in otherwise saving labour.

Hand Labour will now be required in many ways at once; for instance, on the mixed soils it is seldom that the land where the turnips and swedes are being fed-off is quite clean and free from couch grass; and we find it a good plan to have the lumps or bunches forked out before the sheep, as it cannot be seen after the sheep have gone over the land and trodden the ground. We often employ both men and women, but it is light work and suits female labour very well, and they, when accustomed to outdoor work, will do as much at it as men. The Swedish turnips now begin to find of the time of year, and are fast running up to green stalks. To stop them is important at the exact time, otherwise the quality of the roots is depreciated, and when near to towns the greens are a ready sale if not wanted on the farm; and the method of topping the roots must depend upon when and for what purpose the roots will be required. If a good stock of sheep are on the farm which require all, both bulbs and tops, they may be only cut down in the ordinary way by mowing. If, however, there is plenty of food for the sheep the greens may be cut and sold to the market men who attend the towns. We have sometimes made from 20s. to 30s. per acre of them; but should the swedes be required for a late period they may be so managed as to prove good food for sheep and allowed to remain in the land as they grew through the months of May and June, for on various occasions we have not finished feeding with the sheep until after midsummer. Our plan is to pull a road for the carts to enter the field across in various directions for the purpose of carrying away the greens. We adopt the method of what we call crowding down the bulbs, which is cutting the stalks off close to the crown where the rim is formed by the fall of the first leaves. The time to do this is just as the seed buds form a head about the size of a shilling or pennypiece, and this work is done by women, who use a fagging hook, giving each bulb a separate cut, and when cut close down on the crown it is a long time before any young shoots come at all, the buds being cut away, so that if they make any shoot at all it has to be formed on the clean smooth surface of the bulb. The roots bleed a little sap, but not enough to injure their value for feeding or to rot them, and we have had them in excellent feeding condition on many occasions until all our field hay has been made and ricked, and thereby saved large quantities of hay, which must have otherwise been fed as grass, to continue a heavy stock of sheep during the months of May and June. When the roots are fed late in this way we have grown capital white Belgian carrots by one ploughing and sown any time before the 20th of May. The portion of fields fed later does well to be seeded with vetches and oats or tall rape mixed. This plan, however, of feeding on the land to a late period is not so much approved as it has been, because the cultivation and preservation of mangel is better understood, and mangel now forms the staple root food of

the farm during the summer months to supplement grass, &c., for sheep and dairy cows, for which purpose it is admirably adapted, particularly the Golden Tankard variety sold by Sutton of Reading.

PRICKLY COMFREY.

My management is first to plough the ground as deeply as possible, a good dressing of dung being put on previous to ploughing; the land is then harrowed to make it even. We then dig good-sized holes 2 feet 6 inches apart. The land is poor, or we should dig the holes 3 feet apart over the entire piece intended to be planted. We then place two shovelfuls of dung in each hole, and mix a little fine soil with it, stirring the whole together and filling up the holes again. The dung makes the stations appear like little mounds. We then dib in the cuttings or eyes, as may be, one in each mound. When the plants show leaf we give a top-dressing of guano, superphosphate, and dissolved bones at the rate of 1½ cwt. per acre, and have the ground then hoed over to clean it from weeds. After the second cutting another dressing of guano will assist the autumn cutting. In fact, Comfrey cannot be over-manured any more than can rhubarb; each will take any amount of manure, and may have as much liquid manure as can be given. I should not advise your correspondent (see page 195) to rake his manure off the land, but to point it in with a fork. We always manure our Comfrey ground heavily in the winter, and fork the manure in during this month (March). Prickly Comfrey must be fed well and grown quickly, for, like a cucumber, if grown slow it is very bitter, and will even impart to the milk an unpleasant taste.—W. MOWBRAY.

I PLANTED a field of Prickly Comfrey last year, and according to advice it was not cut at all. It is now beginning to shoot well, but has large clusters of last year's decayed leaves attached all round the stem or root. Should these be removed or not, and should the crowns be manured round?—G. M.

[It will be necessary to carefully remove the old dead leaves of last year's growth. As, however, the young shoots now begin to appear it should be done with care, as the new buds are exceedingly tender. The old dried leaves if allowed to remain are certainly an impediment and injurious to the coming produce; and this being a most valuable production for cattle food, it will well repay the grower for properly attending to the plants at all times, and especially by manuring without stint; and at this time of year either Peruvian guano or nitrate of soda and mineral superphosphate may be applied round the plants, and just forked or raked-in with care.]

MANAGEMENT OF POULTRY IN SPRING.

THERE is no time of year during which careful management of poultry, whether bred for exhibition or use, is more necessary than the present. It is a season of cold winds, hot suns, and sudden changes of temperature; and though we have hitherto been favoured with a genial old-fashioned spring, who knows that east winds and snow showers may not yet be in store for us and for our chickens? Many people are enthusiastic about their poultry by fits and starts. They go to the great autumn shows, are filled with admiration of the prize birds, buy one or two fine specimens and send them home, and perhaps look at them daily in their new quarters for a week or two; then interest flags, and the birds are left to the care of some servant who has plenty of other things to attend to, and consequently the birds are pretty much left to take care of themselves. A certain amount of energy, perhaps, revives in their owners upon the arrival of the first brood of chickens; but it is transient, and little trouble is taken with the poultry yard till the next exhibition season, and then there is wonderment and disgust if splendid chickens do not appear both in the show pen and on the table. With the true fancier the early spring, far from being an idle time, is the working season. The management of the breeding stock as well as of their young produce is now all-important, and we will therefore give some results of our experience in both.

Many people seem to think that so long as a pen of birds are good in points, and exist in some sort of condition so that the hens lay eggs, an equally good race of descendants must follow. We need hardly tell any of our readers that this is a great mistake. The development and constitution of the future chickens depend in the first instance on the condition of the parents when the eggs are laid. We were much struck the other day by a letter of Mr. James Long's in a contemporary, in which he pointed out the great necessity of keeping the male birds in good condition during the breeding season, and limiting them to a small number of hens. We have always found the great difficulty in managing breeding stock at this time of year to be that the hens are apt to get too fat, while the cocks, if not specially fed and looked after, will often become emaciated. The fact is, the moult of a cock is a much longer and more exhausting process than that of a hen. We have often known a hen begin laying again in five weeks, having moulted in the interval; but cocks generally take three

months to recover their long hackle and tail feathers; then, perhaps, a sickle is lost by accident and again replaced; the result is that the bird comes out of the moult in an exhausted state, and takes a long time completely to recover. Hens, on the other hand, soon begin laying on flesh; if young they probably lay through the winter, and this keeps them from becoming unduly fat, but old hens often have an interval of three or four months between the moult and commencement of laying, and in the meanwhile become positively obese. The best way is to ascertain their condition by frequently handling them on the perch. Judiciously starve any over-fat birds by shutting them up on prison diet for a few days; and, on the other hand, if the cocks show consumptive tendencies take every opportunity of giving them little private luncheons of delicacies and scraps. They should learn to eat out of their attendant's hand, and so be easily fed apart from the hens. Again, warmth derived from sun is even more necessary to sprightliness and vigour than that obtained by food. Always try to have in a poultry run some wall or hedge under which the birds can sun themselves, protected from the north and east winds; if this cannot be, a little peat or turf bank is a good substitute, or even a hole dug in the ground with the excavated soil thrown up on one side. As a rule we allow them about four hens to one cock in the early spring, but if they are old birds and their quarters cold or confined we should advise that the numbers be reduced to two; indeed, we have this season one or two famous old birds with only a single pullet, to make sure of a vigorous progeny. It is not that the eggs will necessarily be unfertile if more hens are allowed them, but the produce will have no constitution, and will succumb to the first check or chill. So closely do they follow the condition of their parents, that once when we had a poultry servant who greatly overfed the breeding stock, the chickens were all hatched in a state which we should call in the old birds "down behind." They had no power of digestion, and scores died under a week old. Many eggs, too, from birds in soft or poor condition duly develop up to a certain point and then fail. We examine them before a candle after six days or so of incubation and find all going on well, but between that time and the date for hatching vitality fails in the embryo, and they become "addled."

So much for the management of breeding stock. We will now pass on to the chickens. Our readers ought by this time to have their broods coming off in rapid succession—that is, if they are ambitious of seeing spring chickens on the table or of winning prizes at the early chicken shows; indeed, if they keep the Asiatic varieties, which take so long to reach maturity, they must have early chickens if they are to win at all this year. We do not ourselves go in much for very early broods, being chiefly content with later chickens, which are in the end the strongest and finest specimens. However, all should by this time be preparing for young stock. It has been usual in directions for the management of newly-hatched broods to read a list of dainties—boiled eggs, peppered potatoes, curds, and custards, on which they are to be fed in their early days, until promoted to the more ordinary diet of meal and grain. All this pampering we consider, as a rule, wrong; it does not so much do harm at the time, as make it difficult to wean the chicks from those delicacies to their permanent fare. If the change takes place gradually, and the one food is mixed with the other, the little creatures soon find it out and pick it out, leaving the plainer stuff; or if the latter is at once entirely substituted they often refuse it altogether, and pine in consequence. Whatever is to be their staple food, with that they should begin at once; a few tempting morsels may be given in addition, but only now and then, and as a treat. We have found oatmeal and ground oats—i.e., the whole oat ground to meal—by far the best food for general use; this we have boiled or scalded, and sufficient Indian corn meal or barley meal added to make a light crumbly mixture. Chickens will never refuse this if only as much is given at one time as they require, and none left about to turn sour and disgust them. Bread and milk, too, we give occasionally; it should be boiled, and then there is little fear of it giving them diarrhoea; but they must not have more than one meal a-day of it. Weakness of bone is certainly an increasing failing in the larger and heavier breeds. Cockerels are more liable to it than pullets. To what cause it is chiefly attributable we are not prepared to say, probably to a combination of several causes; among them high breeding, an erroneous selection of breeding stock with large bones, which are by no means the same thing as strong bones; and over-stimulating diet, which makes chickens literally outgrow their strength. We have always found it follow feeding on meat or patent meals containing meat. We had long thought this its chief cause, and were confirmed in our opinion last autumn when visiting Lady Gwydyr's yards by hearing from Mr. Wragg, quite independently of any suggestion of our own, that such was his experience. The acknowledged weakness of the teeth of the present generation of Englishmen has been by many eminent dentists attributed to the greater quantity of meat which we eat than our forefathers did. It seems not unlikely that a like diet may have a like effect in weakening the bones of animals or birds. We advise as far as possible a farinaceous and vegetable diet for chickens, save in very inclement weather, when the supply of mixed food entirely

fails. Old mortar should be handy, and we have always been used to have eggshells pounded up and added to the food, according to the advice of that great and practical authority Mrs. Arbuthnot. These hints should enable the fancier to have good hatches and to carry his broods safely through their early days, and we hope to give further advice about the management of the young stock as the season advances.—C.

DEATH OF MR. C. W. JOHNSON, F.R.S.

WE have sorrowfully to record the death of Mr. Cuthbert W. Johnson, F.R.S., so long and so well known as a writer on agricultural subjects. He died at his residence, Waldronhyrst, near Croydon, on the 8th inst., in the seventy-ninth year of his age.

Mr. Johnson was the eldest surviving son of William Johnson, Esq., of Widmore House, Bromley, in Kent, where he was born on the 28th September, 1799. He was also the brother of one of the Editors of this journal, and was a barrister by profession, but he devoted himself so closely to the science and practice of agriculture that he at an early period became widely known as a reliable agricultural writer. In 1820 he published an "Essay on the Uses of Salt for Agricultural Purposes," and this was followed by "The Advantages of Railways to Agriculture" (1837), "On Liquid Manures" (1837), "On Fertilisers" (1839), "The Objects and History of the Thames Improvement Company" (1839), "On Gypsum as a Fertiliser" (1840), "On Saltpetre and Nitrate of Soda as Fertilisers" (1840), "On Increasing the Depths of Soils" (1840). In 1841, conjointly with Mr. Shaw, he began "The Farmers' Almanac," which was the first periodical of that kind, and which has existed uninterruptedly up to the present time. In 1842 he undertook "The Farmers' Encyclopædia," an extensive work of 1820 pages. Then followed "The Farmers' Medical Dictionary" (1845), "The English Rural Spelling Book" (1846), "Our House and Garden" (1867). Besides these there were "A Calendar for Young Farmers," "The Modern Dairyman," and other minor publications. Mr. Johnson held for many years the office of Chairman of the Croydon Local Board of Health, of which he was the original President, and on his retirement from that office in 1877 the Board presented him with a splendid piece of plate as a recognition of his services, on which was the following inscription:—

"Presented to Cuthbert William Johnson, Esq., F.R.S., by his Fellow Members of the Croydon Local Board of Health, in testimony of the valuable assistance in Law and Science rendered by him for upwards of a quarter of a century as their Chairman, and in memory of their high esteem and affectionate regard. 1877."

Mr. Johnson was at the time of his death also a Director of the Royal Farmers' Insurance Company, and Chairman of The Tithe and Rent Guarantee Company.

Thus lived and thus died one of the best of men. He was a willing and an assiduous worker, and his object was useful work, such as would benefit his country and the community. The kindness of his nature, his strict integrity, his firm friendship, and his high sense of honour, will endear him in the memories of all who had the benefit of his acquaintance.—H.

VARIETIES.

"A COUNTRY VICAR," referring to the paragraph on page 196 stating that eggs have been very scarce in January and February, states that in spite of the mild weather the same number of hens with him have produced exactly twice the quantity of eggs that they did in those months last year. No doubt the cause is to be found, says our correspondent, in the roost having been made warmer, but at all events the season is not the cause of eggs being scarce.

It is proposed that an International Agricultural Show be held in London next year, and that every kind of European and, so far as is possible, of American farm and dairy produce shall be represented, and that all attempted solutions of food problems shall be afforded ample space. Live and dead animals, meat killed at a distance and preserved by various methods, butter, cheese, and the methods of producing them, as well as the huge catalogue of agricultural machinery and implements, will make up an exhibition of engrossing interest to the landowners and agricultural population of this country.

BUTTER FROM HOLLAND.—According to the Dutch *Landbouw Courant* the exports to the United Kingdom of two Dutch butter-making firms represent a value of £25,000 weekly, natural and artificial butter both included. For the manufacturing of their artificial butter these two firms use daily 20,000 kilograms of margarine, 8000 litres of new milk, some casks of white American syrup, and other minor ingredients.

AN instance of the damage which mice can commit in a bee hive lately occurred in the garden of Sir H. W. Peek, Bart., at Wimbledon House. Mr. Ollerhead, the gardener, who is a most successful practical bee-keeper, had observed a singular absence of bees in connection with what he conceived was a strong stock in a large Pettigrew hive. On turning up the hive it was tenanted

by five enormous mice, which were imprisoned in the hive and had grown fat on its contents—so fat that they were quite unable to pass through the aperture of the hive by which they must have entered when in quite a small state. The mice had eaten nearly all the bees and brood, and had, in fact, totally ruined a hive which last year yielded 95 lbs. of honey.

It is very certain, says an American writer, that it will not pay to keep pigs running around in what is called "store" condition, but which is often a half-starved state; for although they cost but little for food they pay nothing at all for that little, whereas when well fed from the first they pay all the while, and by being kept in styes they will so enrich any farm with their manure as to bring it up to bear heavy crops.

At the last Whitechapel hay and straw market there was a moderate supply of fodder, the demand for which was good, at slightly increased prices. Prime clover, 100s. to 134s.; inferior ditto, 85s. to 95s.; prime meadow hay, 86s. to 100s.; inferior ditto, 70s. to 80s.; and straw, 44s. to 51s. per load.

WINTERING BEES.

THE large honey supplies from Russia and North America clearly prove that the honey bee lives and flourishes in those countries, where severe winters are the rule not the exception. The extreme dryness of the atmosphere causes their winters to be less severely felt than our more moist and variable ones. There are few who have failed to observe the effects of frost on soft and succulent plants as compared with those dry and well hardened off. The same rule holds good with bees.

Mr. Pettigrew says he "has met with but few records of wild bees and fugitive swarms in Canada, or of honey harvests from them." One would have supposed he would have been much interested in the exploits and sagacity of the Indian bee-hunters in tracing and following-up the flight of those pioneers of civilisation "the white man's fly" to the "bee-tree," so termed by the native Indian, as indicating the approach of European settlements, and thus referred to by the poet Evans:—

"Ere o'er thy cozy leaf 'the white man's fly'
Shall, fear'd no more, her peaceful labours ply,
Enamour'd nestle on thy saffron crest,
Or in thy hollow'd trunk her bee-nymphs rest."
